<td>Gl upset: Dyspepsia</td>
</tr>
</tbody>
</table>

Adverse Reactions of Heparin
- hemorrhage: depends on dose, age, and concomitant use of antiplatelet agents or thrombolytics
- heparin-induced thrombocytopenia: associated with venous or arterial thrombosis (see Table 23, H29)
- osteoporosis: with long-term use

Low Molecular Weight Heparin (enoxaparin, dalteparin, tinzaparin)
- increased bioavailability compared to normal heparin
- increased duration of action
- SC route of administration
- do not need to monitor aPTT
- adverse reactions less common than UFH
- patients with renal failure (CrCl <30) can accumulate LMWH, therefore must adjust dose
- only partially reversible with protamine sulphate

<td>Low dose prophylactic platelet transfusion decreases total number of platelets transfused but increases number of transfusions but not incidence of bleeding in patients with hypoproliferative thrombocytopenia</td>
</tr>
<tr>
<td>ESPIRIT</td>
<td><em>Lancet</em> 2008; 367:1665-73</td>
<td>ASA plus dipyridamole is recommended over ASA alone as antithrombotic therapy after cerebral ischemia of arterial origin</td>
</tr>
<tr>
<td>Hodgkin Lymphoma: ABVD vs. MOPP</td>
<td><em>NEJM</em> 1992; 327:1478-84</td>
<td>In Hodgkin lymphoma, ABVD regimen has equal failure-free and overall survival to MOPP + ABVD, but less myelotoxicity; ABVD is standard chemotherapy for Hodgkin lymphoma</td>
</tr>
<tr>
<td>ITP: Dexamethasone</td>
<td><em>NEJM</em> 2003; 349:831-6</td>
<td>A four-day course of high-dose dexamethasone is effective initial therapy for adults with immune thrombocytopenic purpura</td>
</tr>
<tr>
<td>MInT Group</td>
<td><em>Lancet</em> 2011; 12:1013-1022</td>
<td>Rituximab added to CHOP-like chemotherapy improved long-term outcomes for young patients with good-prognosis DLBCL</td>
</tr>
<tr>
<td>MSH</td>
<td><em>NEJM</em> 1995; 332:1317-22</td>
<td>Hydroxyurea is effective in reduction of complications and clinical manifestations of sickle cell disease</td>
</tr>
<tr>
<td>Platelet Transfusion Threshold</td>
<td><em>NEJM</em> 1997; 337:1870-5</td>
<td>The risk of major bleeding in patients with AML undergoing induction chemotherapy was similar whether the platelet-transfusion threshold was set at 20 or 10; use of the lower threshold reduced platelet usage by 21.5%</td>
</tr>
<tr>
<td>PT1</td>
<td><em>NEJM</em> 2005; 353:85-96</td>
<td>Hydroxyurea plus low-dose ASA is superior to anagrelide plus low-dose ASA for patients with essential thrombocytopenia at high risk for vascular events</td>
</tr>
<tr>
<td>R-CHOP</td>
<td><em>NEJM</em> 2002; 346:235-42</td>
<td>Addition of rituximab to CHOP increases complete response rate and prolongs event-free survival and overall survival in elderly with DLBCL</td>
</tr>
<tr>
<td>StIL</td>
<td><em>Lancet</em> 2013; 381(9873):1203-10</td>
<td>Bendamustine plus rituximab is superior to R-CHOP in terms of progression-free survival and fewer toxic effects in patients with previously untreated indolent lymphoma</td>
</tr>
<tr>
<td>Therapeutic Platelet Transfusion</td>
<td><em>Lancet</em> 2012; 380:1309-16</td>
<td>Therapeutic platelet transfusions (when bleeding occurs) may be used if severe bleeding can be identified early in autologous stem-cell transplant patients; prophylactic transfusion (when platelets &lt;10) should remain standard of care in AML patients</td>
</tr>
<tr>
<td>TRICC</td>
<td><em>NEJM</em> 1999; 340:409-17</td>
<td>A restrictive strategy of red-cell transfusion (when Hb &lt;70) is at least as effective as and possibly superior to a liberal transfusion strategy (when Hb &lt;100) in ICU patients; one possible exception is patients with an acute MI or unstable angina</td>
</tr>
<tr>
<td>VISTA</td>
<td><em>JCO</em> 2010; 28:2259-66</td>
<td>Bortezomib plus melphalan and prednisone (MPV) is superior to melphalan and prednisone (MP) in overall survival of non-transplant-eligible multiple myeloma patients</td>
</tr>

Bacteriology

Bacteria Basics
- bacteria are prokaryotic cells that divide asexually by binary fission
- Gram stain divides most bacteria into two groups based on their cell wall
  - Gram positive (GP): thick, rigid layer of peptidoglycan
  - Gram negative (GN): thin peptidoglycan layer + thicker outer membrane composed of lipopolysaccharides
  - clinical significance: GN thick outer membrane makes it resistant to penicillin's mechanism of action
- AFB: high mycolic acid content in cell wall, "acid fast" as washout phase of Gram stain is ineffective, e.g. Mycobacteria, Nocardia
- "atypical" bacteria: not seen on Gram stain and difficult to culture
- obligate intracellular bacteria: e.g. Mycoplasma
- spirochetes: e.g. Treponema pallidum
- O₂ can be either vital or detrimental to growth
  - obligate aerobes: require O₂
  - obligate anaerobes: require environment without O₂
  - facultative anaerobes: can survive in environments with or without O₂

Mechanisms of Bacterial Disease
1. adherence to and colonization of skin or mucous membranes
   - e.g. fimbriae (pili): microfilaments extending through the cell wall – like burrs sticking to your clothes, they attach to epithelial cells e.g. E. coli in the urinary tract
2. invasion or crossing normal epithelial barriers
3. evasion of host defense system through inhibition of:
   - phagocytic uptake via polysaccharide capsule (S. pneumoniae, N. meningitidis, H. influenzae) or surface proteins (Staphylococcus, Streptococcus)
4. toxin production
   - exotoxins are secreted by living pathogenic bacteria and cause disease even if the bacteria is not present (e.g. Clostridium)
   - endotoxins are structural components of GN bacterial cell wall, and may be shed by live cells or released during cell lysis
5. intracellular growth
   - obligate intracellular: Rickettsia and Chlamydia
   - facultative intracellular: Salmonella, Neisseria, Brucella, Mycobacteria, Listeria, Legionella
6. biofilm
   - an extracellular polysaccharide network forming mesh around the bacteria (e.g. S. epidermidis) which can coat prosthetic devices like IV catheters

### Figure 2. Laboratory identification of bacterial species
Virology

Viral Basics
- Viruses are infectious particles consisting of RNA or DNA covered by a protein coat
  - Infect cells and use host metabolic machinery to replicate
  - Nucleic acid can be double stranded (ds) or single stranded (ss)
  - Can be enveloped or naked
- Virions are mature virus particles that can be released into the extracellular environment
- Host susceptibility is governed by the host cell and virus surface proteins (viral tropism) and cellular immunity

Viral Disease Patterns
1. Acute infections (e.g. adenovirus)
   - Host cells are lysed in the process of virion release
   - Some produce acute infections with late sequelae (e.g. measles virus → subacute sclerosing panencephalitis)
2. Chronic infections (>6 mo): (e.g. HBV, HIV)
   - Host cell machinery is used to produce and chronically release virions
3. Latent infections
   - Viral genome remains latent in host cell nucleus
   - Can reactivate (e.g. HSV, VZV)

Mycology

Fungal Basics
- fungi are eukaryotic organisms, they can have the following morphologies
  1. yeast (unicellular)
  2. molds (also known as filamentous fungi) (multicellular with hyphae)
  3. dimorphic fungi (found as mold at room temperature but grow as yeast-like forms at body temperature)

Table 4. Membrane and Cell Wall Compositions

<table>
<thead>
<tr>
<th>Membrane Sterol</th>

<tbody>
<tr>
<td>Bacteria</td>
<td>–</td>
</tr>
<tr>
<td>Human Cell</td>
<td>Cholesterol –</td>
</tr>
<tr>
<td>Fungi</td>
<td>Ergosterol Chitin</td>
</tr>
</tbody>
</table>

Mechanisms of Fungal Disease
- primary fungal infection by
  - overgrowth of normal flora (e.g. Candida species)
  - inhalation of fungal spores
  - traumatic inoculation into skin
  - toxins produced by fungi (e.g. ingestion aflatoxins)
  - allergic reactions to fungi (e.g. bronchopulmonary aspergillosis)

Parasitology

Parasite Basics
- parasite: an organism that lives in or on another organism (host) and damages the host in the process
- parasites with complex life cycles require more than one host to reproduce
  - reservoir host: maintains a parasite and may be the source for human infection
  - intermediate host: maintains the asexual stage of a parasite or allows development of the parasite to proceed to the larval stage
  - definitive host: allows the parasite to develop to the adult stage where reproduction occurs
- 2 major groups of parasites: protozoa and helminths
- see Tables 26 and 27 for examples of clinically important parasites

Table 5. Differences Between Protozoa and Helminths

<td>Eosinophilia (proportional to extent of tissue invasion)*</td>
</tr>
<tr>
<td>Indefinite life span</td>
<td>Definite life span</td>
</tr>
</tbody>
</table>

*Adult ascaris (roundworm) does not cause eosinophilia

Characteristics of Parasitic Disease
- symptoms are usually proportional to parasite burden
- tissue damage is due to the parasite and host immune response
- chronic infections may occur with or without overt disease
- immunocompromised hosts are more susceptible to manifestations of infection, reactivation of latent infections, and more severe disease
- eosinophilia may suggest a parasitic infection

Mechanisms of Parasitic Disease
1. mechanical obstruction (e.g. ascariasis, clonorchiasis)
2. competition with host for resources (e.g. anemia in hookworm disease, vitamin B₁₂ deficiency in diphyllobothriasis)
3. cytotoxicity leading to abscesses and ulcers (e.g. amoebiasis, leishmaniasis)
4. inflammatory
  - acute hypersensitivity (e.g. pneumonitis in Loeffler’s syndrome)
  - delayed hypersensitivity (e.g. egg granulomas in schistosomiasis)
  - cytokine-mediated (systemic illness of malaria, disseminated strongyloidiasis)
5. immune-mediated injury
  - autoimmune (e.g. myocarditis of Chagas disease, tissue destruction of mucocutaneous leishmaniasis)
  - immune complex (e.g. nephritis of malaria, schistosomiasis)
Transmission of Infectious Diseases

Table 6. Mechanism of Transmission

<table>
<thead>
<tr>
<th>Mechanism</th>
<th>Mode of Transmission</th>
<th>Examples</th>
<th>Preventative Measure*</th>

Prevention of Infectious Diseases

Overview
- efforts to control the spread of infectious disease involves infection control and prevention measures in health care settings and public health measures outside of health care settings

Infection Control and Prevention Measures
1. surveillance for important nosocomial infections or problem organisms (such as: surgical site infections, vascular access-related infections, C. difficile infections, colonization or infections due to antimicrobial resistant organisms e.g. methicillin-resistant S. aureus). (see Population and Community Health, PH19 for a definition of active vs. passive surveillance)
2. routine practices (also known as standard precautions) used for all patients
   - perform hand hygiene before and after seeing patient or patient environment contact, before aseptic procedures, and after body fluid exposure
   - use gloves for any encounter with body fluids
   - wear eye protection, mask, and gown for any procedures likely to generate splashes of body fluids
   - do not recap sharps by hand and dispose of sharps in puncture-resistant container near point-of-use
   - use mouthpieces for resuscitator bags instead of using mouth-to-mouth resuscitation
   - discard soiled waste properly
   - ensure routine cleaning and disinfection of patient environment and patient care equipment
3. additional precautions used for various syndromes or known infectious diseases
   - contact precautions (private room, gown, gloves to be used routinely) (e.g. used for patients with C. difficile)
   - droplet/contact precautions (private room, gown, gloves, eye protection, fluid-resistant mask) (e.g. used for influenza, meningitis due to Neisseria meningitidis)
   - airborne precautions (negative-pressure private room with door closed, fit-tested N95 respirator) (e.g. used for TB, measles, VZV)

Duodenal Infusion of Donor Feces for Recurrent Clostridium difficile
Study: RCT stopped after an interim analysis. Population: 43 patients at least 18 yr of age, with a life expectancy of at least 3 mo, and a relapse of C. difficile after at least one course of adequate antibiotic therapy (>10 d of vancomycin or a dose of ≥125 mg 4/d or >10 d of metronidazole at a dose of 500 mg 3/d). Intervention: Initial vancomycin regimen (500 mg orally 4/d for 4 d) followed by a bowel lavage and infusion of a donor feces solution through a nasoduodenal tube, standard vancomycin regimen (500 mg orally 4/d for 14 d), or a standard vancomycin regimen with bowel lavage. Primary Outcome: Resolution of diarrhea associated with C. difficile infection without relapse after 10 wk. Results: 87% of patients in the group with duodenal infusion of donor feces had a resolution of C. difficile-associated diarrhea after the first infusion. 31% of patients receiving vancomycin with bowel lavage had a resolution of C. difficile-associated diarrhea. After the infusion, patients showed greater fecal bacterial diversity similar to healthy donors. Conclusions: Infusion of donor feces was more effective for the treatment of recurrent C. difficile infection than the use of vancomycin alone or vancomycin with bowel lavage.
4. decolonization (e.g. topical and oral antimicrobials be used in an attempt to decolonize methicillin-resistant \textit{S. aureus} [MRSA])

5. outbreak investigations (see Population and Community Health, PH19)

**Public Health Measures**

1. vaccination
2. post-exposure prophylaxis (e.g. use of immunoglobulin or vaccination post-exposure to infectious disease agents in an attempt to reduce the likelihood or severity of disease)
3. reportable diseases (e.g. list of reportable communicable diseases that physicians are legally required to report to local public health officials) (see Population and Community Health, PH25)
4. contact tracing (tracking of individuals who have been exposed to a person with a communicable disease during its period of communicability)
5. quarantine (restriction of the activities of well persons who have been exposed to a person with a communicable disease during its period of communicability to prevent disease transmission during the incubation period if infection should occur)
6. outbreak investigation (see Population and Community Health, PH19)

**Nosocomial Infections**

- definition: infections acquired >48 h after admission to a healthcare facility or within 30 d from discharge
- risk factors: prolonged hospital stay, antibiotic use, surgery, hemodialysis, intensive care, colonization with a resistant organism, immunodeficiency
- patients with nosocomial infections have higher mortality, longer hospital stays, and higher healthcare costs
- hand hygiene is an essential precaution

Respiratory Infections

Pneumonia

- see Pediatrics, P90
- see Family Medicine, FM18

**Definition**
- infection of the lung parenchyma

**Etiology and Risk Factors**
- impaired lung defenses
  - poor cough/gag reflex (e.g. illness, drug-induced)
  - impaired mucociliary transport (e.g. smoking, cystic fibrosis)
  - immunosuppression (e.g. steroids, chemotherapy, AIDS/HIV, DM, transplant, cancer)
- increased risk of aspiration
  - impaired swallowing mechanism (e.g. impaired consciousness, neurologic illness causing dysphagia, mechanical obstruction)
- no organism identified in 75% of hospitalized cases, and >90% of ambulatory cases

*See Pediatrics P90, Table 45 for Common Causes and Treatment of Pneumonia at Different Ages

**Clinical Features**
- cough (± sputum), fever, pleuritic chest pain, dyspnea, tachypnea, tachycardia
- elderly often present atypically; altered LOC is sometimes the only sign
- evidence of consolidation (dullness to percussion, bronchial breath sounds, crackles)
- features of parapneumonic effusion (decreased air entry, dullness to percussion) (see Respirology, R21)
- complications: ARDS, lung abscess, parapneumonic effusion/empyema, pleuritis ± hemorrhage

**Investigations**
- pulse oximetry to assess severity of respiratory distress
- CBC and differential, electrolytes, urea, Cr, ABG (if respiratory distress), troponin/CK, LFTs, urinalysis
- sputum Gram stain/C&S, blood C&S, ± serology/viral detection, ± pleural fluid C&S (if effusion >5 cm or respiratory distress)
- CXR±CT chest shows distribution (lobar consolidation or interstitial pattern), extent of infiltrate ± cavitation
- bronchoscopy ± washings for:
  - (1) severely ill patients refractory to treatment or (2) immunocompromised patients

**Treatment**
- ABC, O₂, IV fluids, consider salbutamol (nebulized or MDI)
- determine prognosis and need for hospitalization and antibiotics

©Stuart Jantzen 2012

Figure 6. Lobar, broncho, and interstitial pneumonia

When Klebsiella causes pneumonia; see red currant jelly sputum

3 As of Klebsiella
- Aspiration pneumonia
- Alcoholics and diabetics
- Abscess in lungs

Aspiration pneumonias more commonly manifest as infiltrates in the right middle or lower lobes due to the larger caliber and more vertical orientation of the right bronchus

Prevention

- Vaccine for influenza A and B recommended annually for all ages
- Two pneumococcal polysaccharide vaccines available: 23 valent (indicated for all adults) and 13 valent (indicated for adults >50 yr)
- The CDC recommends giving Pevnrix-13 to all adults at high risk for invasive pneumococcal disease (>65 yr, 19-64 with chronic disease, smokers, residents of long-term care facilities, Aboriginal peoples 50-64 yr)
Influenza

Definitions and Etiology
- influenza viruses A and B
- influenza A further divided into subtypes based on envelope glycoproteins:
  - hemagglutinin (H) and neuraminidase (N)
- seasonal (epidemic) influenza
  - main circulating influenza viruses: human-origin A (H1N1) and B (H3N2) subtypes
  - associated with antigenic drift (gradual, minor changes due to random point mutations)
  - may create a new viral subtype resulting in a seasonal epidemic (disease prevalence is greater than expected)
  - outbreaks occur mainly during winter months (late December to early March)
- pandemic influenza
  - associated with antigenic shift: abrupt, major changes due to mixing of two different viral strains from different hosts
  - may create a new viral strain resulting in a pandemic outbreak (worldwide)
  - antigenic shift occurs only in type A
- transmission: droplet, possibly airborne

</tbody>
</table>

Clinical Features
- incubation period 1-4 d
- acute onset of systemic (fever, chills, myalgias, arthralgias, headache, fatigue) and respiratory symptoms (cough, dyspnea, pharyngitis)
- complications: respiratory (viral pneumonia, secondary bacterial pneumonia, otitis media, sinusitis), muscular (rhabdomyolysis, myositis), neurologic (encephalitis, meningitis, transverse myelitis, Guillain-Barré syndrome)

Investigations
- diagnosis is primarily clinical based on symptoms during the influenza season
- nasopharyngeal swabs for rapid antigen detection, DFA (Direct Fluorescent Antigen) detection, RT-PCR (gold standard)
- serology: rarely used for clinical management

Treatment and Prevention
- primarily supportive unless severe infection or high-risk of complications (e.g. elderly, pulmonary or cardiac disease)
- neuraminidase inhibitors: zanamivir (Relenza*) and oseltamivir (Tamiflu*) for treatment and prophylaxis against types A and B
  - decreases duration (by 1-2 d) and severity of symptoms if given within <48 h of onset
  - treatment beyond 48 h time window may be warranted in immunosuppressed and critically ill patients
- M2-inhibitors: amantidine/rimantidine for treatment and prophylaxis against type A only no longer recommended due to increased resistance
- vaccine for influenza A and B viruses is recommended annually for all ages
  - vaccine is reformulated each year to reflect circulating influenza A and B strains

Skin and Soft Tissue Infections

Cellulitis

Definition
- acute infection of the skin principally involving the dermis and subcutaneous tissue

Etiology
- common causative agents: S. aureus, β-hemolytic streptococci
- immunocompromised patients or water exposure: may also include GN rods and fungi
- risk factors:
  - trauma with direct inoculation, recent surgery
  - peripheral vascular disease, lymphedema diabetes, cracked skin in feet/toes (tinea pedis)
Clinical Features
- pain, edema, erythema with indistinct borders ± regional lymphadenopathy, systemic symptoms (fevers, chills, malaise)
- can lead to ascending lymphangitis (visible red streaking in skin along lymphatics proximal to area of cellulitis)

Investigations
- CBC and differential, blood C&S if febrile
- skin swab ONLY if open wound with pus

Treatment
- antibiotics: cephalexin (broader coverage if risk factors for GN rods)
- if extensive erythema or systemic symptoms, consider cefazolin IV
- limb rest and elevation may help reduce swelling

Necrotizing Fasciitis

Definition
- life- and limb-threatening infection of the deep fascia characterized by rapid spread

Etiology
- Two main forms
  - Type I: polymicrobial infection – aerobes and anaerobes (e.g. S. aureus, Bacteroides, Enterobacteriaceae)
  - Type II: monomicrobial infection with GAS

Clinical Features
- pain out of proportion to clinical findings and beyond border of erythema
- edema, ± crepitus (subcutaneous gas from anaerobes), ± fever
- infection spreads rapidly
- patients may rapidly become very sick (tachycardia, hypotension, lightheadedness)
- late findings
  - skin turns dusky blue and black (secondary to thrombosis and necrosis)
  - induration, formation of hemorrhagic bullae

Investigations
- a clinical/surgical diagnosis – do NOT wait for results of investigations before beginning treatment
- blood and tissue C&S
- serum CK (elevated CK usually means myonecrosis – a late sign)
- plain film x-ray (soft tissue gas may be visualized)
- surgical exploration for debridement of infected tissue

Treatment
- resuscitation with IV fluids
- emergency surgical debridements to confirm diagnosis and remove necrotic tissue (may require amputation)
- IV antibiotics
  - unknown organism: meropenem or piperacillin/tazobactam + clindamycin IV ± vancomycin if MRSA is considered
  - Type I (polymicrobial): piperacillin/tazobactam + clindamycin IV
  - Type II (monomicrobial): penicillin G + clindamycin IV
  - with Type II, evaluate for streptococcal toxic shock syndrome and the need for IVIg

Gastrointestinal Infections

Acute Diarrhea
- see Gastroenterology, G15
- see Pediatrics, P35
- see Family Medicine, FM26

Epidemiology
- one of the top five leading causes of death worldwide, according to the World Health Organization
- significant morbidity in developed countries (over 900,000 hospitalizations in United States each year)
Definition
• passage of ≥3 loose or liquid stools/d OR >200 g stool/d for >2 d but ≤14 d

Approach to Acute Diarrhea
• rationale
  ▪ the vast majority of acute diarrhea is caused by infection
  ▪ in most cases, acute diarrheal illness is viral and/or self-limited, and lasts <3 d
  ▪ investigations are costly and are necessary only in certain circumstances
  ▪ therefore, the evaluation of acute diarrhea involves:
    ▪ identifying characteristics of the illness or patient that warrant further investigation
    ▪ assessing volume status to determine appropriate method of rehydration
  ▪ see Figure 7

Physical Exam
• volume status: appearance, level of alertness, pulse, BP, orthostatic vitals, JVP, mucous membranes, skin turgor, capillary refill
• abdominal exam: pain, guarding, peritoneal signs

Treatment
• rehydration is mainstay of treatment
  ▪ oral rehydration therapy
  ▪ IV rehydration if oral intake insufficient to replace fluid loss
• antidiarrheal agents reduce duration of diarrhea: loperamide, bismuth salicylate
  ▪ delays excretion of causative pathogens
  ▪ contraindications: diarrhea with fever, bloody stool or diarrhea caused by *Clostridium difficile*
• antibiotic therapy is rarely indicated because:
  ▪ most acute diarrheal illness is viral and self-limited
  ▪ antibiotics can eradicate normal gut flora, predisposing patient to *C. difficile* infection
  ▪ antibiotics prolong the shedding of *Salmonella* and other causes of bacterial diarrhea
  ▪ in EHEC infection, antibiotics may increase the risk of HUS
  ▪ indications for antibiotic therapy are shown in Figure 7

![Figure 7. Approach to acute diarrhea](image-url)

</tbody>
</table>
Traveler’s Diarrhea

• see Acute Diarrhea, ID11

Epidemiology
• the most common illness to affect travelers
• up to 50% of travelers to developing countries affected in first 2 wk and 10-20% after returning home

Etiology
• bacterial (80-90%): E. coli most common (ETEC), Campylobacter, Shigella, Salmonella, Vibrio (non-cholera); wide regional variation (e.g. Campylobacter more common in Southeast Asia)
• viral: norovirus, rotavirus, and astrovirus account for 5-8%
• protozoal (rarely): Giardia, Entamoeba histolytica, Cryptosporidium, Cyclospora for ~10% in long-term travelers
• pathogen-negative traveler’s diarrhea common despite exhaustive microbiological workup

Treatment
• rehydration is the mainstay of therapy
  ➤ rehydrate with sealed beverages
  ➤ in severe fluid loss use oral rehydration solutions (1 package in 1 L boiled or treated water)
• treat symptoms: antidiarrheal agents (e.g. bismuth salicylate, loperamide)
• empiric antibiotics in moderate or severe illness: ciprofloxacin or azithromycin or rifaximin
  ➤ note: there is increasing fluoroquinolone resistance in causative agents, especially in Southeast Asia

Prevention
• proper hygiene practices
  ➤ avoid consumption of: foods or beverages from establishments with unhygienic conditions (e.g. street vendors), raw fruits or vegetables without a peel, raw or undercooked meat and seafood
  ➤ avoid untreated water
  ➤ bismuth salicylate (Pepto-Bismol®): 60% effective (2 tablets qid according to CDC website)
  ➤ CDC Guidelines: antibiotic prophylaxis not recommended
  ➤ increased risk of infection with resistant organisms

**Traveler’s Diarrhea**: Bismuth salicylate (Pepto-Bismol®) can cause patients to have black stools, which may be mistaken for melena.
• high risk groups (e.g. immunocompromised) likely to be infected with pathogen not covered by standard antimicrobial agents
• Dukoral®: oral vaccine that offers protection against V. cholerae (efficacy ~80%) and ETEC (efficacy ~50-67%); the CDC does not recommend it for routine use in travelers

**Chronic Diarrhea**

• see Gastroenterology, G16

**Peptic Ulcer Disease (H. pylori)**

• see Gastroenterology, G12

**Bone and Joint Infections**

**Septic Arthritis**

**Routes of Infection**
• hematogenous (adults)
• contiguous osteomyelitis (children)
• direct inoculation via skin/trauma
• iatrogenic (surgery, arthroscopy, arthrocentesis)

**Etiology**
• gonococcal
  ▪ N. gonorrhoeae: previously accounted for 75% of septic arthritis in young sexually active adults
• non-gonococcal
  ▪ S. marcescens: affects all ages, rapidly destructive, accounts for most non-gonococcal cases of septic arthritis in adults (especially in those with rheumatoid arthritis)
  ▪ Streptococcus species (Group A and B)
  ▪ Gram-negatives: affects neonates, elderly, IV drug users, immunocompromised
  ▪ S. pneumoniae: affects children
  ▪ Kingella kingae: affects children aged <2 yr since Hib immunization (Hib possible cause in unvaccinated children)
  ▪ Salmonella spp.: characteristic of sickle cell disease
  ▪ coagulase-negative Staphylococcus species: prosthetic joints
• if culture negative: Borrelia spp. (Lyme disease) or Tropheryma whipplei (Whipple’s disease)

**Risk Factors**
• gonococcal
  ▪ age (<40 yr), multiple partners, unprotected intercourse, MSM
• non-gonococcal
  ▪ bacteremia (extra-articular infection with hematogenous seeding, endocarditis)
  ▪ prosthetic joints/recent joint surgery
  ▪ underlying joint disease (rheumatoid arthritis, osteoarthritis)
  ▪ immunocompromise (DM, chronic kidney disease, alcoholism, cirrhosis)
  ▪ loss of skin integrity (cutaneous ulcer, skin infection)
  ▪ age >80 yr

**Clinical Features of Gonococcal Arthritis**
• two forms (although overlap often)
  ▪ bacteremic form
    ▪ systemic symptoms: fever, malaise, chills
  ▪ gonococcal triad: migratory polyarthritis, tenosynovitis, dermatitis (pustular skin lesions)
  ▪ septic arthritis form
    ▪ local symptoms in involved joint: swelling, warmth, pain, inability to bear weight, marked decrease in range of motion (see Rheumatology, RH3 for differential diagnosis)

**Clinical Features of Non-Gonococcal Arthritis**
• acute onset of pain, swelling, warmth, decreased range of motion ± fever, chills
• most often in large weight-bearing joints (knee, hip, ankle) and wrists
• usually monoarticular (polyarticular risk factors: rheumatoid arthritis, endocarditis, GBS)
Infections

- consider rheumatologic causes for monoarthritis (see Rheumatology, RH3)
- gonococcal: blood C&S, as well as endocervical, urethral, rectal, and oropharyngeal testing
- non-gonococcal: blood C&S
- arthrocentesis (synovial fluid analysis) is mandatory: CBC and differential, Gram stain, C&S, examine for crystals
  - infectious = opaque, increased WBCs (>15,000/mm³; likelihood of infection increases with increasing WBCs), PMNs >90%, culture positive
  - growth of N. gonorrhoeae from synovial fluid is successful in <50% of cases
- ± plain x-ray: assess for osteomyelitis, provides baseline to monitor treatment

Treatment

- medical
  - empirical IV antibiotics (vancomycin + ceftriaxone) – delay may result in joint destruction
  - Gram stain guides subsequent treatment
  - gonococcal: ceftriaxone + azithromycin, for concurrent treatment of C. trachomatis
  - non-gonococcal: antibiotics against Streptococcus spp. (2 wk IV f/b PO), S. aureus (4 wk IV minimum), or GNB (4 wk)
- surgical drainage if: (see Orthopedics, OR10)
  - persistent positive joint cultures on repeat arthrocentesis
  - hip joint involvement
  - prosthetic joint
- daily joint aspirations until culture sterile; no need to give intra-articular antibiotics
- physiotherapy

Prognosis

- gonococcal: responds well after 24-48 h of initiating antibiotics (usually complete recovery)
- non-gonococcal: up to 50% morbidity (decreased joint function/mobility)

Diabetic Foot Infections

Etiology

- neuropathy, peripheral vascular disease, and hyperglycemia contribute to foot ulcers that heal poorly and are predisposed to infection
- organisms in mild infection: S. aureus, Streptococcus spp.
- organisms in moderate/severe infection: polymicrobial with aerobes (S. aureus, Streptococcus, Enterococcus, GNB) and anaerobes (Peptostreptococcus, Bacteroides, Clostridium)

Clinical Features

- not all ulcers are infected
- consider infection if: probe to bone (see below), ulcer present >30 d, recurrent ulcers, trauma, PVD, prior amputation, loss of protective sensation, renal disease, history of walking barefoot
- diagnosis of infected ulcer: ≥2 of the cardinal signs of inflammation (redness, warmth, swelling, pain) or the presence of pus
- ± crepitus, osteomyelitis, systemic toxicity
- visible bone or probe to bone → osteomyelitis
- infection severity:
  - mild = superficial (no bone/joint involvement)
  - moderate = deep (beneath superficial fascia, involving bone/joint) or erythema >2 cm
  - severe = infection in a patient with systemic toxicity (fevers, tachypnea, leukocytosis, tachycardia, hypotension)

Investigations

- curettage specimen from ulcer base, aspirate from an abscess or bone biopsy (results from superficial swabs do not represent organisms responsible for deeper infection)
- blood C&S if febrile
- assess for osteomyelitis by x-ray (although not sensitive in early stages) or MRI if high clinical suspicion
  - if initial x-ray normal, repeat 2-4 wk after initiating treatment to increase test sensitivity

Treatment

- evaluate for early surgical debridement ± revascularization or amputation
- eliminate/reduce pressure and provide regular local wound care
- mild: cephalixin or clindamycin
- moderate: clindamycin + ciprofloxacin or moxifloxacin PO, ceftriaxone or ertapenem IV ± MRSA coverage
- severe: piperacillin/tazobactam or meropenem IV ± vancomycin if MRSA known or suspected
- encourage glycemic control

Diabetic Foot Infections

Etiology

- neuropathy, peripheral vascular disease, and hyperglycemia contribute to foot ulcers that heal poorly and are predisposed to infection
- organisms in mild infection: S. aureus, Streptococcus spp.
- organisms in moderate/severe infection: polymicrobial with aerobes (S. aureus, Streptococcus, Enterococcus, GNB) and anaerobes (Peptostreptococcus, Bacteroides, Clostridium)

Clinical Features

- not all ulcers are infected
- consider infection if: probe to bone (see below), ulcer present >30 d, recurrent ulcers, trauma, PVD, prior amputation, loss of protective sensation, renal disease, history of walking barefoot
- diagnosis of infected ulcer: ≥2 of the cardinal signs of inflammation (redness, warmth, swelling, pain) or the presence of pus
- ± crepitus, osteomyelitis, systemic toxicity
- visible bone or probe to bone → osteomyelitis
- infection severity:
  - mild = superficial (no bone/joint involvement)
  - moderate = deep (beneath superficial fascia, involving bone/joint) or erythema >2 cm
  - severe = infection in a patient with systemic toxicity (fevers, tachypnea, leukocytosis, tachycardia, hypotension)

Investigations

- curettage specimen from ulcer base, aspirate from an abscess or bone biopsy (results from superficial swabs do not represent organisms responsible for deeper infection)
- blood C&S if febrile
- assess for osteomyelitis by x-ray (although not sensitive in early stages) or MRI if high clinical suspicion
  - if initial x-ray normal, repeat 2-4 wk after initiating treatment to increase test sensitivity

Treatment

- evaluate for early surgical debridement ± revascularization or amputation
- eliminate/reduce pressure and provide regular local wound care
- mild: cephalixin or clindamycin
- moderate: clindamycin + ciprofloxacin or moxifloxacin PO, ceftriaxone or ertapenem IV ± MRSA coverage
- severe: piperacillin/tazobactam or meropenem IV ± vancomycin if MRSA known or suspected
- encourage glycemic control
Osteomyelitis

- see Orthopedics, OR10

Cardiac Infections

Infective Endocarditis

Definition
- infection of cardiac endothelium, most commonly the valves
- classifications: acute vs. subacute, native valve vs. prosthetic valve, right-sided vs. left-sided
- leaflet vegetations that are comprised of platelet-fibrin thrombi, WBCs, and bacteria

Risk Factors and Etiology
- predisposing conditions
  - high risk: prosthetic cardiac valve, previous IE, congenital heart disease (unrepaired, repaired within 6 mo, repaired with defects), cardiac transplant with valve disease (surgically constructed systemic-to-pulmonary shunts or conduits)
  - moderate risk: other congenital cardiac defects, acquired valvular dysfunction, hypertrophic cardiomyopathy
  - low/no risk: secundum ASD or surgically repaired ASD < VSD, PDA, MV prolapse, ischemic heart disease, previous CABG
- opportunity for bacteremia: IVDU, indwelling venous catheter, hemodialysis, poor dentition, DM, HIV
- frequency of valve involvement MV >> AV > TV > PV
  - but in 50% of IVDU-related IE the tricuspid valve is involved

Table 16. Microbial Etiology of Infective Endocarditis Based on Risk Factors

Organisms in bold are the most common isolates.
1. Streptococcus includes mainly Viridans group streptococci
2. Other includes less common organisms such as:
   - Streptococcus bovis (usually associated with underlying GI malignancy, cirrhosis)
   - Culture-negative organisms including nutritionally-deficient streptococci, HACEK, Bartonella, C. burnetii, C. pneumoniae, Legionella, Brucella
   - Candida
3. IVDU endocarditis pathogens depend on substance used to dilute the drugs (i.e. tap water = Pseudomonas, saliva = oral flora, toilet water = GI flora)

Clinical Features
- systemic
  - fever (80-90%), chills, weakness, rigors, night sweats, weight loss, anorexia
- cardiac
  - dyspnea, chest pain, clubbing (subacute)
  - regurgitant murmur (new onset or increased intensity)
  - signs of CHF (secondary to acute MR, AR)
- embolic/vascular
  - petechiae over legs, splinter hemorrhages (linear, reddish-brown lesion within nail bed)
  - Janeway lesions (painless, 5 mm, erythematous, hemorrhagic pustular lesions on soles/palms)
  - focal neurological signs (CNS emboli), headache (mycotic aneurysm)
  - splenomegaly (subacute)
  - microscopic hematuria, flank pain (renal emboli) ± active sediment
- immune complex
  - Osler’s nodes (painful, raised, red/brown, 3-15 mm on digits)
  - glomerulonephritis
  - arthritis
  - Roth’s spots (retinal hemorrhage with pale center)

Diagnosis
- Modified Duke Criteria, see Table 17
  - definitive diagnosis if: 2 major, OR 1 major + 3 minor, OR 5 minor
  - possible diagnosis if: 1 major + 1 minor, OR 3 minor
### Table 17. Modified Duke Criteria

#### Major Criteria (2)

1. Positive blood cultures for IE
   - Typical microorganisms for IE from 2 separate blood cultures ([Streptococcus viridans](#), [HACEK group](#), [Staphylococcus bovis](#), [Streptococcus faecalis](#), community-acquired enterococci) OR
   - Persistently positive blood culture, defined as recovery of a microorganism consistent with IE from blood drawn > 12 h apart or all of 3 or a majority of 4 or more separate blood cultures, with first and last drawn > 1 h apart OR
   - Single positive blood culture for [Coxiella burnetii](#) or antiphase I IgG antibody titer > 1:800

2. Evidence of endocardial involvement
   - Positive echocardiogram for IE (oscillating intracardiac mass on valve or supporting structures, or in the path of regurgitant jets, or on implanted material in the absence of an alternative anatomic explanation OR abscess OR new partial dehiscence of prosthetic valve) OR
   - New valvular regurgitation (insufficient if increase or change in preexisting murmur)

#### Minor Criteria (5)

1. Predisposing condition (abnormal heart valve, IVDU)
2. Fever (100.4°F/38.0°C)
3. Vascular phenomena: major arterial emboli, septic pulmonary infarcts, mycotic aneurysms, ICH, conjunctival hemorrhages, Janeway lesions
4. Immunologic phenomena: glomerulonephritis, rheumatoid factor, Osler’s nodes, Roth’s spots
5. Positive blood culture but not meeting major criteria OR serologic evidence of active infection with organism consistent with IE

#### Investigations

- serial blood cultures: 3 sets (each containing one aerobic and one anaerobic sample) collected from different sites >1 h apart
  - persistent bacteremia is the hallmark of endovascular infection (such as IE)
- repeat blood cultures (at least 2 sets) after 48 to 72 h of appropriate antibiotics to confirm clearance
- blood work: CBC and differential (normochromic, normocytic anemia), ESR (increased), RF (+), BUN/Cr
- urinalysis (proteinuria, hematuria, red cell casts) and urine C&S
- ECG: prolonged PR interval may indicate perivalvular abscess
- Echo findings: vegetations, regurgitation, abscess
  - TTE (poor sensitivity) inadequate in 20% (obesity, COPD, chest wall deformities)
  - TEE indicated if TTE is non-diagnostic in patients with at least possible endocarditis or if suspect prosthetic valve endocarditis or complicated endocarditis (e.g. paravalvular abscess/perforation) (~90% sensitivity)

#### Treatment

- medical
  - usually non-urgent and can wait for confirmation of etiology before initiating treatment
  - empiric antibiotic therapy if patient is unstable; administer ONLY after blood cultures have been taken
    - first-line empiric treatment for native valve: vancomycin
    - first line empiric treatment for prosthetic valve: vancomycin + gentamicin + cefepime OR a carbapenem
  - targeted antibiotic therapy: antibiotic and duration (usually 4-6 wk) adjusted based on valve, organism, and sensitivities
  - monitor for complications of IE (e.g. CHF, conduction block, new emboli) and complications of antibiotics (e.g. interstitial nephritis)
  - prophylaxis only for high risk individuals listed above with dental procedures that may lead to bleeding OR invasive procedure of the respiratory tract that involves incision or biopsy of the respiratory mucosa, such as tonsillectomy and adenoidectomy OR procedures on infected skin, skin structure, or musculoskeletal tissue
    - dental/respiratory: amoxicillin single dose 30-60 min prior; clindamycin if penicillin-allergic
    - skin/soft tissue: cephalexin single dose 30-60 min prior; clindamycin if penicillin-allergic (modify based on etiology of skin/soft tissue infection)
  - surgical
    - most common indication is refractory CHF
    - other indications include: valve ring abscess, fungal etiology, valve perforation, unstable prosthesis, ≥2 major emboli, antimicrobial failure (persistently positive blood cultures), mycotic aneurysm, staphylococci on a prosthetic valve

#### Prognosis

- adverse prognostic factors: CHF, prosthetic valve infection, valvular/myocardial abscess, embolization, persistent bacteremia, altered mental status prognostic factors: CHF, prosthetic valve infection, valvular/myocardial abscess
- mortality: prosthetic valve IE (25-50%), non-IVDU *S. aureus* IE (30-45%), IVDU *S. aureus* or streptococcal IE (10-15%)
Neurological Infections

Meningitis

• see Pediatrics, P61

Definition
• inflammation of the meninges

Etiology

Risk Factors
• lack of immunization against S. pneumoniae, H. influenzae type b in children
• hematogenous spread after invasion from a mucosal surface (nasopharynx)
• parameningeal focus (otitis media, infection, sinusitis)
• penetrating head trauma
• anatomical meningeval defects – CSF leaks
• previous neurosurgical procedures, shunts
• immunocompromise (corticosteroids, HIV, asplenia, hypogammaglobulinemia, complement deficiency)
• contact with colonized or infected persons

Clinical Features
• neonates and children: fever, vomiting, lethargy, irritability, poor feeding
• older children and adults: fever, H/A, neck stiffness, confusion, N/V, lethargy, photophobia, altered level of consciousness, seizures, focal neurological signs, papilledema
• petechial rash in meningococcal meningitis, seen more frequently on trunk or lower extremities

Investigations
• blood work: CBC and differential, electrolytes (for SIADH), blood C&S
  - CSF: opening pressure, cell count + differential, glucose, protein, Gram stain, bacterial C&S
  - AFB, fungal C&Ss, cryptococcal antigen in immunocompromised patients, subacute illness, suggestive travel history or TB exposure
  - PCR for HSV, VZV, enteroviruses, WNV if viral cause suspected
• imaging/neurologic studies: CT, MRI, EEG if focal neurological signs present

Treatment
• bacterial meningitis is a medical emergency: do not delay antibiotics for CT or LP
• empiric antibiotic therapy
  • age <1 mo: ampicillin + cefotaxime IV OR ampicillin ± an aminoglycoside IV
  • age >1 mo: vancomycin + cefotaxime OR ceftriaxone IV
    • add ampicillin IV if risk factors for infection with L. monocytogenes present: age >50, alcoholism, immunocompromised
• steroids in acute bacterial meningitis: dexamethasone IV within 20 min prior to or with first dose of antibiotics
  • continue in those patients with proven pneumococcal meningitis
  • not recommended for patients with suspected bacterial meningitis in some resource-limited countries
Prevention
- see Pediatrics, P3
- immunization
  - children: immunization against H. influenzae (Pentacel®), S. pneumoniae (Synflorix®, Prevnar-13®), N. meningitidis (Menjugate®, Menactra®)
  - adults: immunization against N. meningitidis in selected circumstances (outbreaks, travel, epidemics) and S. pneumoniae (Pneumovax®) for high-risk groups
- prophylaxis: close contacts of patients infected with H. influenzae should be treated with rifampin if they live with an inadequately immunized (<4 yr) or immunocompromised child (<18 yr); ciprofloxacin, rifampin, or ceftriaxone if close or household contact of a patient with N. meningitidis

Prognosis
- complications
  - H/A, seizures, cerebral edema, hydrocephalus, SIADH, residual neurological deficit (especially CN VIII), deafness, death
- mortality
  - S. pneumoniae 25%; N. meningitidis 5-10%; H. influenzae 5%
  - worse prognosis if: extremes of age, delays in diagnosis and treatment, stupor or coma, seizures, focal neurological signs, septic shock at presentation

Encephalitis

Definition
- inflammation of the brain parenchyma

Etiology
- identified in only 40-70% of cases
  - when cause is identified, the most common etiology is viral
  - e.g. HSV, VZV, EBV, enteroviruses, CMV, West Nile, HIV, mumps, measles, rabies, polio
  - bacteria: L. monocytogenes, Mycobacteria, spirochetes (Lyme, syphilis)
  - parasites: protozoa (e.g. Toxoplasma) and helminths (rare)
  - fungi: e.g. Cryptococcus
  - post-infectious (e.g. acute disseminated encephalomyelitis [ADEM])

Pathophysiology
- acute inflammatory disease of the brain due to direct invasion or pathogen-initiated immune response
- viruses may reach the CNS via peripheral nerves (e.g. rabies, HSV)
- herpes simplex encephalitis
  - acute, necrotizing, asymmetrical hemorrhagic process with lymphocytic and plasma cell reaction which usually involves the medial temporal and inferior frontal lobes
  - associated with HSV-1, but can also be caused by HSV-2

Clinical Features
- constitutional: fever, chills, malaise, N/V
- meningeal involvement (meningoencephalitis): H/A, nuchal rigidity
- parenchymal involvement: seizures, altered mental status, focal neurological signs
- herpes simplex encephalitis
  - acute onset (<1 wk) of focal neurological signs: hemiparesis, ataxia, aphasia, focal or generalized seizures
  - temporal lobe involvement: behavioral disturbance
  - usually rapidly progressive over several days and may result in coma or death
  - common sequelae: memory and behavior disturbances

Investigations
- CSF: opening pressure, cell count + differential, glucose, protein, Gram stain, bacterial C&S, PCR for HSV, VZV, EBV, enteroviruses, and other less common viral etiologies
- serology: may aid diagnosis of certain causes of encephalitis (e.g. West Nile virus)
- imaging/neurologic studies: CT, MRI, EEG to define anatomical sites affected
- invasive testing: brain tissue biopsy may be required for culture, histological examination, and immunocytochemistry (if diagnosis not clear via non-invasive means)
- findings in herpes simplex encephalitis (must rule out due to high mortality)
  - CT/MRI: medial temporal lobe necrosis
  - EEG: early focal slowing, periodic discharges

Treatment
- general supportive care
- monitor vital signs carefully
- IV acyclovir empirically until HSV encephalitis ruled out

Meningococcal Quadrivalent Vaccine
- Healthy young adults (not immunized in childhood)
- Asplenia
- Travelers to high-risk areas
- Military recruits or laboratory personnel
- Complement, factor D, or properdin deficiency or acquired terminal complement deficiency through receipt of eculizumab

Meningococcal Quadrivalent Vaccine (Menactra® or Menomune®)
- Healthy young adults (not immunized in childhood)
- Asplenia
- Travelers to high-risk areas
- Military recruits or laboratory personnel
- Complement, factor D, or properdin deficiency or acquired terminal complement deficiency through receipt of eculizumab

Meningitis and encephalitis patients can be distinguished based on their cerebral function. Cerebral function is abnormal in encephalitis patients (e.g. altered mental status, motor or sensory deficits, altered behavior, speech or movement disorders), but may be normal in patients with meningitis. Note however, that there is considerable overlap between the two syndromes ("meningoencephalitis").
Generalized Tetanus

- see Family Medicine, FM3
- see Pediatrics, P3

Etiology and Pathophysiology
- caused by *Clostridium tetani*: motile, spore forming, anaerobic GP bacillus
- found in soil, splinters, rusty nails, GI tract (humans and animals)
- traumatic implantation of spores into tissues with low oxygenation (e.g. puncture wound, burns, nonsterile surgeries or deliveries)
- upon inoculation, spores transform into *C. tetani* bacilli that produce tetanus toxin
  - toxin travels via retrograde axonal transport to the CNS where it irreversibly binds presynaptic neurons to prevent the release of inhibitory neurotransmitters (e.g. GABA)
  - net effect is the disinhibition of spinal motor reflexes which results in tetany and autonomic hyperactivity

Clinical Features
- generalized tetanus
  - initially present with painful spasms of masseters (trismus or "lockjaw")
  - sustained contraction of skeletal muscle with periodic painful muscle spasms (triggered by sensory stimuli, e.g. loud noises)
  - paralysis descends to involve large muscle groups (neck, abdomen)
  - apnea, respiratory failure, and death secondary to tonic contraction of pharyngeal and respiratory muscles
- autonomic hyperactivity
  - diaphoresis, tachycardia, HTN, fever as illness progresses

Investigations
- primarily a clinical diagnosis, often although not always with a history of a traumatic wound and lack of immunization
- culture wounds, CK may be elevated

Treatment
- stop toxin production
  - wound debridement to clear necrotic tissue and spores
  - antimicrobial therapy: IV metronidazole, penicillin G IV is an effective alternative
- neutralize unbound toxin with tetanus immune globulin (TIG)
- supportive therapy: intubation, spasmolytic medications (benzodiazepines), quiet environment, cooling blanket
- control autonomic dysfunction: α- and β-blockade (e.g. labetalol), magnesium sulfate

Prevention
- infection with *C. tetani* does not produce immunity – vaccinate patients on diagnosis
- tetanus toxoid vaccination (see Pediatrics, P3/Emergency Medicine, ER17)

Rabies

Definition
- acute progressive encephalitis caused by RNA virus (family: *Rhabdoviridae*, genus *Lyssavirus*)

Etiology and Pathophysiology
- any mammal can transmit the rabies virus
  - most commonly transmitted by raccoon, skunk, bat, fox, cat, and dog; monkeys also a risk in the developing world
- transmission: breaching of skin by teeth or direct contact of infectious tissue (saliva, neural tissue) with skin or mucous membranes
  - almost all cases due to bites
- virus travels via retrograde axonal transport from PNS to CNS
- virus multiples rapidly in brain, then spreads to other organs, including salivary glands
- development of clinical signs occurs simultaneously with excretion of rabies virus in saliva
  - infected animal can transmit rabies virus as soon as it shows signs of disease

Clinical Features
- five stages of disease
  1. incubation period
     - 1-3 mo on average (can range from days to years)
  2. prodrome (<1 wk)
     - influenza-like illness: low-grade fever, malaise, anorexia, N/V, H/A, sore throat
     - pain, pruritus, paresthesia may occur at wound site
once prodromal symptoms develop, there is rapid, irreversible progression to death
• progression from prodrome to coma and death may occur without an intervening acute
  neurologic syndrome
3. acute neurologic syndrome: 3 types (<1 wk)
a. encephalitic (most common): hyperactivity, fluctuating LOC, hydrophobia, aerophobia,
  hypersalivation, fever, seizures
  • painful pharyngeal spasms on encountering gust of air or swallowing water cause
    aerophobia and hydrophobia, respectively
b. paralytic: quadriplegia, loss of anal sphincter tone, fever
c. atypical: rare
4. coma
  • complete flaccid paralysis, respiratory and cardiovascular failure
5. death (within days to weeks of initial symptoms)

Investigations
• purpose of diagnosis by investigations is to limit patient contact with others and to identify
  others exposed to the infectious source
• ante-mortem: direct immunofluorescence or PCR on multiple specimens: saliva, skin biopsy,
  serum, CSF
• post-mortem: direct immunofluorescence in nerve tissue, presence of Negri bodies (inclusion
  bodies in neurons)

Treatment
• post-exposure prophylaxis depends on regional prevalence (contact Public Health) and
  circumstances surrounding injury
• three general principles
  • wound care: clean wound promptly and thoroughly with soap and running water
  • passive immunization: HRIg infiltrated into wound site, with any remaining volume
    administered IM in anatomical site distant from vaccine administration
  • active immunization: inactivated rabies virus vaccine (series of shots post-exposure)
• treatment is supportive once victim manifests signs and symptoms of disease

Prevention
• pre-exposure vaccination
  • recommended for high risk persons: laboratory staff working with rabies, veterinarians,
    animal and wildlife control workers, long-term travelers to endemic areas

Systemic Infections

Sepsis and Septic Shock

• see Respirology, R33

Definitions
• systemic inflammatory response syndrome (SIRS): two or more of
  1. temperature <96.8°F/36°C or >100.4°F/38°C
  2. heart rate >90 beats per minute
  3. respiratory rate >20 breaths per minute or PaCO2 <32 mmHg
  4. WBC <4 x 10⁹/L or >12 x 10⁹/L or >10% bands
• sepsis: SIRS + proven or provable infection
• severe sepsis: sepsis + signs of end-organ dysfunction and hypoperfusion
• septic shock: severe sepsis + hypotension (<90 mmHg sBP), despite adequate fluid resuscitation

Pathophysiology
• causative agents are identified in only 50-70% of cases
• when organisms are identified, GP and GN organisms are the cause in 90% of cases
• primary bloodstream infection or secondary bacteremia → local immune response →
  immune cells release pro-inflammatory cytokines → immune response spreads beyond local
  environment → unregulated, exaggerated systemic immune response → vasodilation and
  hypotension → involvement of tissues remote from the site of injury/infection resulting in
  multiple major organ dysfunction → periodic immunoparalysis

Clinical Features
• history: fever, chills, dyspnea, cool extremities, fatigue, malaise, anxiety, confusion
• physical: abnormal vitals (fever, tachypnea, tachycardia, hypotension), local signs of infection

Investigations
• CBC and differential, electrolytes, BUN, creatinine, liver enzymes, ABG, lactate, INR, PT, FDP,
  blood CS&x3, urinalysis, urine CS& and cultures of any wounds or lines
• CXR (other imaging depends on suspicion of focus of infection)
Treatment (also see Respirology, R33)
- respiratory support: O2 ± intubation
- cardiovascular support: IV fluids, ± norepinephrine + ICU
- IV antibiotics (empirical, depends on suspected source)
  - start with broad spectrum antibiotics (piperacillin/tazobactam or meropenem) ± additional agents depending on patient risk factors, suspected etiology of infection, and local microbial susceptibilities (± aminoglycoside for drug-resistant GNs or vancomycin for MRSA)
  - narrow once susceptibilities are known
- hydrocortisone IV in patients with septic shock unresponsive to fluid resuscitation and vasopressors

Leprosy (Hansen’s Disease)

Etiology
- *Mycobacterium leprae*: obligate intracellular bacteria, slow-growing (doubling time 12.5 d), survives in macrophages
- bacteria transmitted from nasal secretions, potentially via skin lesions
- invades skin and peripheral nerves leading to chronic granulomatous disease

Clinical Features
- lesions involve cooler body tissues (e.g. skin, superficial nerves, nose, eyes, larynx)
- spectrum of disease determined by host immune response to infection
  i. paucibacillary "tuberculoid" leprosy (intact cell-mediated immune response)
    - ≤5 hypoesthetic lesions, usually hypopigmented, well-defined, dry
    - early nerve involvement, enlarged peripheral nerves, neuropathic pain
  ii. multibacillary "lepromatous" leprosy (weak cell-mediated immune response)
    - ≥6 lesions, symmetrical distribution
    - leonine facies (nodular facial lesions, loss of eyebrows, thickened ear lobes)
  iii. borderline leprosy
    - lesions and progression lies between tuberculoid and lepromatous forms

Investigations
- skin biopsy down to fat or slit skin smears for AFB, PCR
- histologic appearance: intracellular bacilli in spherical masses (lepra cells), granulomas involving cutaneous nerves

Treatment (WHO Treatment Regimens)
- paucibacillary: dapsone + rifampin monthly x 6 mo
- single skin lesion paucibacillary: single dose of rifampicin, ofloxacin, and minocycline
- multibacillary and borderline: dapsone + rifampin monthly + clofazimine monthly x 12 mo
  AND low dose clofazimide once daily x 12 mo
- treatment of leprosy can cause an immune reaction to killed bacteria (e.g. erythema nodosum leprosum and reversal reaction): symptomatic management with NSAIDs if mild, prednisone with 6-12 wk taper if severe; thalidomide for erythema nodosum leprosum

Prognosis
- curable with WHO-approved treatment regimens
- complications: muscle atrophy, contractures, trauma/superinfection of lesions, crippling/loss of limbs, erythema nodosum leprosum
- long post-treatment follow-up warranted to monitor for relapse and immune reactions

Lyme Disease

Etiology/Epidemiology
- spirochete bacteria: *Borrelia burgdorferi* (N. America), *B. garinii, B. afzelii* (Europe and Asia)
- transmitted by Ixodes tick
- reported in 49 of the 50 U.S. states, but most cases occur in the Northeast, the Midwest, and Northern California
- small rodents (mice) serve as primary reservoir, while larger animals (white tailed deer) serve as hosts for ticks
- human contact usually May-August in fields with low brush near wooded areas
- infection usually requires >36 h tick attachment
Clinical Features
- stage 1 (early localized stage: 7-14 d post-bite)
  - malaise, fatigue, H/A, myalgias
  - erythema migrans: expanding, non-pruritic bulls-eye (target) lesions (red with clear center) on thigh/groin/axilla
- stage 2 (early disseminated stage): weeks post-infection
  - CNS: aseptic meningitis, CN palsies (CN VII palsy), peripheral neuritis
  - cardiac: transient heart block or myocarditis
- stage 3 (late persistent stage: months to years post-infection)
  - may not have preceding history of early stage infection
  - MSK: chronic monoarticular or oligoarticular arthritis
  - neurologic: encephalopathy, meningitis, neuropathy

Investigations
- serology: ELISA, Western blot

Prevention
- use of protective clothing (tuck pants into socks), insect repellent, inspection for ticks and prompt removal of tick
- doxycycline prophylaxis within 72 h of removal of an engorged, *Ixodes scapularis* tick in hyperendemic area (local rate of infection of ticks ≥20%) for patients >8 yr who are not pregnant or lactating

Treatment
- stage 1: doxycycline/amoxicillin/cefuroxime
- stage 2-3: ceftriaxone

Toxic Shock Syndrome

Etiology
- superantigens produced by some strains of *S. aureus* or GAS cause widespread T-cell activation and pro-inflammatory cytokine release (IL-1, IL-6, TNF)
- course of disease is precipitous and leads to acute fever, shock, multiorgan failure
- Staphylococcal TSS involves the production of superantigen TSST-1 (toxic shock syndrome toxin 1)
- Streptococcal TSS involves the production of superantigens SPEA, SPEB, SPEC

Risk Factors
- Staphylococcal: tampon use, nasal packing, wound infections (e.g. postpartum vaginal or Cesarean or other surgical infections)
- Streptococcal: minor trauma, surgical procedures, preceding viral illness (chickenpox), use of NSAIDs

Clinical Features and Investigations
- acute onset
- Staphylococcal TSS
  - *T* >102°F
  - sBP <90 mmHg
  - diffuse erythroderma with subsequent desquamation, especially on palms and soles
  - involvement of 3 or more organ systems: GI (vomiting, diarrhea), muscular (myalgia, increased CK), mucous membranes (hyperemia), renal, hepatic, hematologic (thrombocytopenia), CNS (disorientation)
  - isolation of *S. aureus* is not required for diagnosis (*S. aureus* is rarely recovered from blood in TSS)
- Streptococcal TSS
  - sBP <90 mmHg
  - isolation of GAS from a normally sterile site (e.g. blood, pleural, tissue biopsy, or surgical wound)
  - ≥2 of coagulopathy, liver involvement, ARDS, soft tissue necrosis (necrotizing fasciitis, myositis, gangrene), renal impairment, erythematous macular rash that may desquamate

Treatment
- supportive: fluid resuscitation
- Staphylococcal: IV clindamycin + (cloxacillin or vancomycin depending on susceptibilities)
- Streptococcal: IV penicillin and clindamycin and IV Ig
Cat Scratch Disease

Etiology
- *Bartonella henselae*: intracellular bacteria
- cat-to-human transmission via cat scratch/bite

Clinical Features
- skin lesion appears 3-10 d post-inoculation
- may be followed by fever, tender regional lymphadenopathy
- in some patients, organism may disseminate causing hepatosplenomegaly, neurologic symptoms
- usually self-limited

Investigations
- serology, lymph node biopsy

Treatment
- supportive in most cases
- azithromycin x 10-14 d in patients with moderate-severe disease or immunocompromise

Rocky Mountain Spotted Fever

Etiology
- *Rickettsia rickettsii*: obligate intracellular GN organism
- reservoir hosts: rodents, dogs
- vectors: *Dermacentor* ticks
- organisms cause inflammation of endothelial lining of small blood vessels, causing small hemorrhages and thrombi
- can cause widespread vasculitis leading to H/A, CNS changes and can progress to death if treatment is delayed

Clinical Features
- usually occurs in summer following tick bite
- influenza-like prodrome: acute onset fever, H/A, myalgia, N/V, anorexia
- macular rash appearing on day 2-4 of fever
  - begins on wrists and ankles, then spreads centrally to arms/legs/trunk/palms/soles
  - occasionally "spotless" (10% of patients)

Investigations
- skin biopsy and serology (indirect fluorescent antibody test)

Treatment
- doxycycline, usually 5-7 d (3 days after afebrile)

West Nile Virus

Epidemiology
- virus has been detected throughout the United States and much of southern Canada
- overall case-fatality rates in severe cases are ~10%

Transmission
- primarily from mosquitoes that have fed on infected birds (crows, blue jays)
- transplacental, blood products (rare), organ transplantation

Clinical Features
- most are asymptomatic
- most symptomatic cases are mild (West Nile fever): acute onset of H/A, back pain, myalgia, anorexia, maculopapular non-pruritic rash involving chest, back, arms
- severe complications: encephalitis, meningoencephalitis and acute flaccid paralysis (especially in those >60 yr)

Investigations
- IgM antibody in serum or CSF (cross reactivity with yellow fever and Japanese encephalitis vaccines, and with dengue fever and St. Louis virus infection); may not reflect current illness as IgM antibody can last for >6 mo
- viral isolation by PCR from CSF, tissue, blood and fluids (all have low sensitivity)
- CSF: elevated lymphocytes and protein if CNS involvement
Treatment and Prevention

- treatment: supportive
- prevention: mosquito repellant (DEET), drain stagnant water, community mosquito control programs

Syphilis

Etiology

- *Treponema pallidum*: thick motile spirochetes historically detectable by dark-field microscopy
- transmitted sexually, vertically, or parenterally (rare)

Clinical Features

- see Dermatology, D30 and Gynecology, GY27
- multi-stage disease
  - i. primary syphilis (3-90 d post-infection)
    - painless chancre at inoculation site (any mucosal surface)
    - regional lymphadenopathy
    - acute disease lasts 3-6 wk, 25% progress to secondary syphilis without treatment
  - ii. secondary syphilis = systemic infection (2-8 wk following chancre)
    - maculo-papular non-pruritic rash including palms and soles
    - generalized lymphadenopathy, low grade fever, malaise, H/A, aseptic meningitis, ocular/otic syphilis
    - condylomata lata: painless, wart-like lesion on palate, vulva, or scrotum (highly infectious)
  - iii. latent syphilis
    - asymptomatic infection that follows untreated primary/secondary syphilis
    - early latent (<1 yr post-infection) or late latent/unknown duration (>1 yr post-infection)
    - increased transmission risk with early latent; longer treatment duration required for late latent
  - iv. tertiary syphilis (1-30 yr post-infection)
    - gummatous syphilis: nodular granulomas of skin, bone, liver, testes, brain
    - aortic aneurysm and aortic insufficiency
    - neurosyphilis: dementia, personality changes, Argyll-Robertson pupils, tabes dorsalis
  - v. congenital syphilis
    - causes spontaneous abortions, stillbirths, congenital malformations, developmental delay, deafness
    - infants may be asymptomatic until age 2-5 yr then present with rhinitis, lymphadenopathy, hepatosplenomegaly, bone and cartilage degeneration (including saddle nose, saber shins), CN VIII deafness

Investigations

- screening tests: VDRL or RPR (non-treponemal), EIA (treponemal)
- confirmatory tests: FTA-ABS, MHA-TP, TPPA, TPI, dark field microscopy with silver stain (rarely)
- LP for neurosyphilis if: seropositive and symptoms of neurosyphilis or treatment failure/other tertiary symptoms, or with HIV and late latent/unknown duration syphilis; consider in others

Treatment

- for 1ª, 2ª, early latent: benzathine penicillin G 2.4 million units IM x 1
- for 3ª, late latent: benzathine penicillin G 2.4 million units IM weekly x 3
- if allergic to penicillin: doxycycline 100 mg PO bid x 14 d
- neurosyphilis: aqueous Penicillin G 18-24 million units/d IV x 14 d
- see Family Medicine, FM4S for generalized STD workup
**Tuberculosis**

**Etiology, Epidemiology, and Natural History**
- 1/3 of the world's population is infected with TB
- contracted by aerosolized inhalation of *Mycobacterium tuberculosis*, a slow growing aerobe (doubling time = 18 h) that can evade innate host defenses, survive, and replicate in macrophages
- inhalation and deposition in the lung can lead to one of the following outcomes:
  1. immediate clearance of the pathogen
  2. latent TB: asymptomatic infection contained by host immune defenses (represents 95% of infected people)
  3. primary TB: symptomatic, active disease (represents 5% of infected people)
  4. secondary TB: symptomatic reactivation of previously dormant TB (represents 5-10% of those with latent TB, most often within the first 2-3 yr of initial infection) at a pulmonary or extra-pulmonary site

**Risk Factors**
- social and environmental factors
  - travel or birth in country with high TB prevalence (e.g. Asia, Latin America, Sub-Saharan Africa, Eastern Europe)
  - Aboriginal, crowded living conditions, low SES/homeless, IVDU
  - personal or occupational contact
- host factors
  - immunocompromised/immunosuppressed (especially HIV, including extremes of age)
  - silicosis
  - chronic renal failure requiring dialysis
  - malignancy and chemotherapy
  - substance abuse (e.g. drug use, alcoholism, smoking)

**Clinical Features**
- primary infection usually asymptomatic, although progressive primary disease may occur, especially in children and immunosuppressed patients
- secondary infection/reactivation usually produces constitutional symptoms (fatigue, anorexia, night sweats, weight loss) and site-dependent symptoms
  i. pulmonary TB
    - chronic productive cough ± hemoptysis
    - CXR consolidation or cavitation, lymphadenopathy
    - non-resolving pneumonia despite standard antimicrobial therapy
  ii. miliary TB
    - widely disseminated spread especially to lungs, abdominal organs, marrow, CNS
    - CXR: multiple small 2-4 mm millet seed-like lesions throughout lung
  iii. extrapulmonary TB
    - lymphadenitis, pleurisy, pericarditis, hepatitis, peritonitis, meningitis, osteomyelitis (vertebral = Pott's disease), adrenal (causing Addison's disease), renal, ovary

*Population denominations obtained from Statistics Canada*
**Investigations**
- screening for latent TB
  - PPD/Mantoux skin tests
    - both tests diagnose prior TB exposure; neither can diagnose or exclude active disease
  - IFN-γ release assay (IGRA):
    - in patients previously infected with TB, T-cells produce increased amounts of IFN-γ when re-exposed to TB antigen
    - detects antigen not present in the BCG vaccine or in most types of non-tuberculous-mycobacteria (NTM), therefore fewer false positives
  - American guidelines treat IGRAs as equivalent to the TB skin test and preferable in patients with a history of BCG vaccination or who may not return for skin test reading
- diagnostic tests/investigations for active pulmonary TB
  - morning sputum on 3 consecutive days for acid-fast bacilli smear and culture
  - BAL
  - CXR
    - nodular or alveolar infiltrates with cavitation (middle/lower lobe if primary, apical if secondary)
    - pleural effusion (usually unilateral and exudative) may occur independently of other radiograph abnormalities
    - hilar/mediastinal adenopathy (especially in children)
    - tuberculoma (semi-calciﬁed well-deﬁned solitary coin lesion 0.5-4 cm that may be mistaken for lung CA)
    - miliary TB
    - evidence of past disease: calcified hilar and mediastinal nodes, calcified pulmonary focus, pleural thickening with calciﬁcation, apical scarring

**Prevention**
- primary prevention
  - airborne isolation for active pulmonary disease
  - BCG vaccine
    - ~80% effective against pediatric miliary and meningeal TB
    - effectiveness in adults debated (anywhere from 0-80%)
    - routine use rarely recommended in American population, however widely used in other countries
- secondary prevention (defer in pregnancy unless mother is high risk)
  - likely INH-sensitive: isoniazid (INH) + pyridoxine (vit B6 to help prevent INH-associated neuropathy) x 9 mo
  - likely INH-resistant: rifampin x 4 mo

**Treatment of Active Infection**
- empiric therapy: INH + rifampin + pyrazinamide + ethambutol + pyridoxine
- pulmonary TB: INH + rifampin + pyrazinamide + ethambutol + pyridoxine x 2 mo (initiation phase), then INH + rifampin + pyridoxine x 4 mo in fully susceptible TB (continuation phase), total 6 mo
- extrapulmonary TB: same regimen as pulmonary TB but increase to 12 mo in bone/joint, CNS, and miliary/disseminated TB + corticosteroids for meningitis, pericarditis
- empiric treatment of suspected MDR (multidrug resistant) or XDR (extensively drug-resistant) TB requires referral to a specialist
  - MDR = resistance to INH and rifampin ± others
  - XDR = resistance to INH + rifampin + fluoroquinolone + ≥1 of injectable, second-line agents
  - very difﬁcult to treat, global public health threat
  - suspect MDR TB if previous treatment, exposure to known MDR index case, or immigration from a high-risk area
- note: TB is a reportable disease to Public Health (please see Center for Disease Control website http://www.cdc.gov/tb/ for more information)
HIV and AIDS

Epidemiology

American Situation (Center for Disease Control, 2012)
- at the end of 2009, an estimated 1,148,200 persons aged 13 and older were living with HIV infection in the United States, including 207,600 (18.1%) persons whose infections had not been diagnosed
- approximately 50,000 people in the United States are newly infected with HIV each year; in 2010 (the most recent year that data are available), there were an estimated 47,500 new HIV infections

Global Situation (WHO and UNAIDS Core Epidemiology Slides, December 2013)
- estimated 35.5 million people living with HIV/AIDS in 2012
- estimated 2.3 million newly infected in 2012
- estimated 1.6 million AIDS-related deaths in 2012

Definition and Pathophysiology

- HIV is a retrovirus that causes progressive immune system dysfunction which predisposes patients to various opportunistic infections and malignancies
- HIV virion includes an envelope (gp41 and gp120 glycoproteins), matrix (p17) and capsid (p24) enclosing 2 single-stranded copies of RNA + enzymes in its core
- virion glycoproteins bind CD4 and CXCR4/CCR5 on CD4+ T lymphocytes (T-helper cells) to fuse and enter the cells
- RNA converted to dsDNA by reverse transcriptase; dsDNA is integrated into host genome
- virus DNA transcribed and translated using host cell machinery, post-translational modifications include proteolytic activity of virally encoded protease enzymes
- newly produced virions bud out of host cell, incorporating host cell membrane; additional maturation steps are required before virion is considered infectious
- exact mechanisms of CD4 depletion incompletely characterized but likely include direct viral cytopathic effects, apoptosis, increased cell turnover

Modes of Transmission

NOTE: these estimates are for “all comers” i.e. they estimate transmission risk for anyone with HIV infection and do not take into account treatment status of the HIV+ person (in contrast to results of PARTNER study)
Natural History

Figure 10. Relationships between CD4 T-cell count, viral load, and anti-HIV antibodies

Acute (Infection) Retroviral Syndrome
- 40-90% experience an acute "flu-like" illness (may include fever, pharyngitis, lymphadenopathy, rash, arthralgias, myalgias, H/A, GI symptoms, oral ulcers, weight loss) 2-6 wk post-exposure lasting 10-15 d
- hematologic disturbances (lymphopenia, thrombocytopenia)
- 10-20% present with aseptic meningitis; HIV RNA and/or p24 may be detected in CSF
- associated with a high level of plasma viremia and therefore high risk of transmission

Asymptomatic (Latent) Stage
- during latent phase, HIV infects and replicates in CD4+ T lymphocytes (lymph nodes)
- normal CD4 count: 500-1,100 cells/mm³
- CD4 count drops 60-100 cells/mm³ per year
- by 10 yr post-infection, 50% have AIDS, 30% demonstrate milder symptoms, and <20% are asymptomatic if left untreated

AIDS Definition in United States
- CD4+ T-lymphocyte count of <200 cells/μL OR
- CD4+ T-lymphocyte percentage of total lymphocytes of <14% OR
- documentation of an AIDS-defining condition

Table 21. Symptomatic Stage (CD4 count thresholds for classic clinical manifestations)

</tr>
</tbody>
</table>

Laboratory Diagnosis
- anti-HIV antibodies detectable after a median of 3 wk, virtually all by 3 mo (therefore 3 mo window period)
- initial screening test (3rd generation antibody test): enzyme linked immunosorbsent assay (ELISA) detects serum antibody to HIV; sensitivity >99.5%
• increasingly, combination p24 antigen/HIV antibody tests (4th generation) used for screening; improved sensitivity in early or acute infection and sensitivity/specificity approach 100% for chronic infection

• confirmatory test: in positive screen, Western blot confirmation by detection of antibodies to at least two different HIV protein bands (p24, gp41, gp120/160); specificity >99.99%

• rapid (point of care) antibody tests: higher false positives, therefore need to confirm positive results with traditional serology

• p24 antigen: detection by ELISA may be positive during "window period"

### Management of the HIV-Positive Patient

- verify positive HIV test
- complete baseline history and physical exam, then follow-up every 3-6 mo
- laboratory evaluation
  - routine CD4 count to measure status of the immune system
  - routine HIV RNA levels (viral load)
    - also important indicator of effect of ART
  - baseline HIV resistance testing to guide ARV therapy
  - HLA-B*5701 genetic test to screen for abacavir hypersensitivity
  - baseline tuberculin skin test (PPD): induration greater than 5 mm is positive
  - baseline serologies (hepatitis A, B, and C, syphilis, toxoplasma, CMV, VZV)
  - routine biochemistry and hematology, CXR
  - annual fasting lipid profile and fasting glucose (due to HAART side effects)
- education
  - regular follow-up on CD4 counts and viral loads (q3-6 mo) as well as strict adherence to ART improves prognosis
  - prevention of further transmission through safer sex and clean needles for injection drug use
  - HIV superinfection (transmission of different HIV strains from another HIV+ person) does rarely occur so barrier protection during sex is still recommended
  - discuss importance of disclosing HIV status to partners including risk of criminal prosecution of non-disclosure in jurisdictions where applicable
  - connect to relevant community groups and resources
- health care maintenance
  - assessment of psychosocial concerns and referral to psychiatry or social work if appropriate
  - vaccines: influenza annually, 23-valent pneumococcal every 5 yr, HBV (if not immune), HAV (if seronegative)
  - annual screening (PAP smear, STDs)
  - management of comorbid conditions and provision of general primary care

SS = single strength; DS = double strength

### Anti-Retroviral Treatment

#### Overall Treatment Principles

- recommended that all HIV+ patients initiate HAART to prevent disease progression and transmission; strength of evidence supporting that recommendation changes depending on CD4 count and sexual practices (AI evidence that CD4 <350 should be on HAART)
- patients starting HAART should be committed to treatment and understand the importance of adherence; poor compliance can lead to viral resistance; may defer treatment on the basis of CD4 count and sexual practices (AI evidence that CD4 <350 should be on HAART)
- initiate ART if opportunistic infection/malignancy, pregnancy, HIV-associated nephropathy, HIV-associated thrombocytopenia, need for hepatitis B therapy in HBV co-infected patients
- consider starting treatment early if HCV co-infection, high HIV viral load, comorbid conditions (e.g. cardiovascular disease)
- consider results of baseline resistance testing and complete ART history before (re-) initiating HAART
- goal keep viral load below limit of detection i.e. <40 copies/mL (undetectable); viral load should decrease 10-fold within 4-8 wk, be undetectable by 6 mo and restore immunological function
- strong evidence against intermittent HAART or 'drug holidays'
- ART leads to 96% reduction in risk of transmitting HIV to sexual partners

- ART improves prognosis
- also important indicator of effect of ART
- CD4 count: progress and stage of disease
- Viral load: rate of progression

- Seroconversion: Development of detectable anti-HIV antibodies
- Window Period: Time between infection and development of anti-HIV antibodies (e.g. when serologic tests (ELISA, Western blot) are negative)

- HIV Status
  - CD4 count: progress and stage of disease
  - Viral load: rate of progression

- 1" and 2" prophylaxis may be discontinued if CD4 count is above threshold for >6 mo while on ART

- HLA-B*5701 Testing
  - Abacavir hypersensitivity reactions usually only occur in individuals carrying this HLA allele (~5-7% of Caucasians, lower prevalence in other ethnic groups).
  - Routine screening for HLA-B*5701 at baseline and definitely prior to abacavir use

- Reasons for Deterioration of a Patient with HIV/AIDS
  - Opportunistic infections
  - Neoplasms
  - Medication-related toxicities
  - Co-infections (e.g. HBV, HCV, STDs)
  - Non-AIDS-related comorbidities (e.g. cardiovascular, renal, hepatic, neurocognitive, bone disease)
HAART Recommendations for Treatment of Naïve Patients
- 2 NRTIs + 1 NNRTI/PI (boosted with ritonavir)/INSTI

Treatment Failure
- defined clinically (HIV progression), immunologically (failure to increase CD4 count by 25-50 over first year of treatment or CD4 decrease >100 over 1 yr), or virologically (failure to achieve viral load <40 copies/mL after 6 mo)
- ensure that viral load >40 is not just a transient viremia or 'blip'; confirm medication adherence, assess drug interactions, resistance testing

Prevention of HIV Infection

- education, including harm-reduction
  - safer sexual practices: condoms for vaginal and anal sex, barriers for oral sex
  - harm reduction for injection drug users: avoid sharing needles
- treatment of HIV+ women with HAART during the 2nd and 3rd trimester of pregnancy and AZT during delivery followed by treatment of the infant for 6 wk (decreases maternal-fetal transmission from 25% to <3%)
- universal blood and body precautions for health care workers
  - post-exposure prophylaxis (PEP) after occupational (e.g. needle-stick injury) and non-occupational (e.g. consensual sex, sexual assault) exposure to HIV: 2- or 3-drug regimen initiated immediately (<72 h) after exposure and continuing for 4 wk
- recent data has demonstrated efficacy of pre-exposure prophylaxis (oral PrEP or topical microbicides) in preventing HIV although additional data needed
- ART associated with 96% reduction in risk of transmitting HIV to sexual partners
- screening of blood and organ donation
**Types of Testing**

1. **Nominal/Name-Based HIV Testing**
   - the person ordering the test knows the identity of the person being tested for HIV
   - the HIV test is ordered using the name of the person being tested
   - person ordering the test is legally obligated to notify Public Health officials if test results are positive for HIV
   - the test result is recorded in the health care record of the person being tested

2. **Non-Nominal/Non-Identifying HIV Testing**
   - similar to nominal/name-based testing on all points except:
     - the HIV test is ordered using a code or the initials of the person being tested

3. **Anonymous Testing**
   - available at specialized clinics
   - the person ordering the HIV test does not know the identity of the person being tested
   - the HIV test is carried out using a unique non-identifying code that only the person being tested for HIV knows
   - test results are not recorded on the health care record of the person being tested
   - patient identification and notification of Public Health required to gain access to ART

**HIV Pre- and Post-Test Counseling**

- a diagnosis of HIV can be overwhelming and is often associated with stigma and discrimination
- consider pre- and post-test counseling, regardless of the results
- goals include: assessing risk, making informed decision to be tested, education to protect themselves and others from virus exposure, where to go for more information and support
- HIV+ patients should be connected with local support services

**Fungal Infections**

**Skin and Subcutaneous Infections**

**Superficial Fungal Infections**

- see Dermatology, D23

**Dermatophytes**

- see Dermatology, D25

**Subcutaneous Fungal Infection**

**Pathophysiology**

- fungi that naturally reside in soil and enter skin via traumatic break
- *Sporothrix schenckii*: most commonly affects gardeners injured by a rose thorn or splinter
  - causes subcutaneous nodule at point of entry
  - fungi may migrate up lymphatic vessels creating nodules along the way – “nodular lymphangitis”

**Treatment**

- oral azole (e.g. itraconazole)
- IV amphotericin B for severe or disseminated infection

**Endemic Mycoses**

**Basics**

- three major endemic mycoses in North America
  - histoplasmosis
  - blastomycosis
  - coccidioidomycosis
thermally dimorphic organisms: mold in cold temperature (e.g. soil) and yeast at higher temperature (e.g. tissue)
• infection occurs through inhalation of spores (soil, bird droppings, vegetation) or inoculation injury
• all can cause pneumonia and may disseminate hematogenously
• may reactivate or disseminate during immunocompromise

Treatment
• common to all endemic mycoses
  ▪ oral azole (e.g. itraconazole for mild-moderate local infection)
  ▪ IV amphotericin B for systemic infection

Table 25. Endemic Mycoses

<table>
<thead>
<tr>
<th>Disease</th>
<th>Endemic Region</th>
<th>Clinical Features</th>
<th>Investigations</th>
</tr>
</thead>
</table>
| Histoplasma capsulatum | Ohio and Mississippi River valleys in central USA, Ontario, Quebec; widespread | Asymptomatic (in most people) \[Primary pulmonary\]
  • Fever, cough, chest pain, headache, myalgia, anorexia
  • CXR (acute): pulmonary infiltrates ± hilar lymphadenopathy
  • CXR (chronic): pulmonary infiltrates, cavitary disease
  Disseminated (rare)
  • Occurs primarily in immunocompromised patients
  • Spread to bone marrow (pancytopenia), GI tract (ulcers), lymph nodes (lymphadenitis), skin, liver, adrenals, CNS
| Fungal culture, fungal stain
| Antigen detection (urine and serum) Serology |
| Blastomyces dermatitidis | States east of Mississippi River, Northern Ontario and along the Great Lakes | May be asymptomatic \[Primary: acute or chronic pneumonia\]
  • Fever, cough, chest pain, chills, night sweats, weight loss
  • CXR (acute): lobar or segmental pneumonia
  • CXR (chronic): lobar infiltrates, fibronodular interstitial disease
| Disseminated
  • Spread to skin (verrucous lesions that mimic skin cancer, ulcers, subcutaneous nodules), bones (osteomyelitis, osteolytic lesions), GU tract (prostatitis, epididymitis)
| Sputum smear and culture
| Direct examination of clinical specimens for characteristic broad-based budding yeast (sputum, tissue, purulent material) |
| Coccidioides immitis | Deserts in southwest USA, northwest Mexico | Primary \[“Valley fever”: subacute fever, chills, cough, chest pain, sore throat, fatigue that lasts for weeks to months\]
  • Can develop hypersensitivity with arthralgias, erythema nodosum
| Disseminated
  • Rare spread to skin (ulcers), joints (synovitis), bones (lytic lesions), meninges (meningitis)
| Common opportunistic infection in patients with HIV
| Sputum culture
| Direct examination of clinical specimens for characteristic yeast (sputum, tissue, purulent material) |

Opportunistic Fungi

Pneumocystis jiroveci (formerly P. carinii)

Microbiology
• unicellular fungi
• previously classified as a protozoa

Transmission
• rarely person-to-person transmission
• most disease is due to reactivation of latent infection acquired by the respiratory route or reinfection by a different genotype
• causes clinical disease in immunocompromised patients (steroid use, HIV)
• 80% lifetime risk without prophylaxis (TMP/SMX) in HIV patients with CD4 count <200 cells/mm³

Clinical Features
• symptoms of pneumonia: fever, nonproductive cough, progressive dyspnea
• classic CXR

Investigations
• demonstration of organism in induced sputum, bronchoalveolar lavage, or endotracheal aspirate (if intubated)
Treatment and Prevention
- oxygen to keep \( \text{SaO}_2 > 90\% \)
- antimicrobial options
  - TMP/SMX (PO or IV) *First line
  - dapsone and TMP
  - clindamycin and primaquine
  - pentamidine (IV)
  - atovaquone
- corticosteroids used as adjuvant therapy in those with severe hypoxia (\( \text{pO}_2 < 70 \text{ mmHg} \) or \( \Delta \text{a}_{\text{O}_2} > 35 \text{ mmHg} \))
- prophylactic TMP/SMX for those at high risk of infection (HIV patients when CD4 < 200 cells/mm\(^3\) or non-HIV immunocompromised patients under specific conditions)

**Cryptococcus spp.**

**Microbiology**
- encapsulated yeast found worldwide
- 2 human pathogenic species: C. gattii, C. neoformans

**Transmission**
- inhalation of airborne yeast from soil contaminated with pigeon droppings (C. neoformans) or certain tree species such as Eucalyptus or Douglas fir (C. gattii) → may cause local infection in lung → asymptomatic or pneumonia
- may also spread hematogenously to the CNS, skin, bones, and other organs
- C. neoformans tends to affect immunocompromised hosts
- C. gattii tends to affect immunocompetent hosts

**Clinical Features**
- pulmonary
  - usually asymptomatic or self-limited pneumonitis
  - only 2% of HIV+ patients present with pulmonary symptoms including productive cough, chest tightness, and fever
- disseminated
  - frequently disseminates in HIV+ population
  - CNS: meningitis (leading cause of meningitis in patients with HIV)
  - skin: umbilicated papules that resemble large lesions of *Molluscum contagiosum*

**Investigations**
- serum cryptococcal antigen
- CSF for meningitis: India-ink stain, cryptococcal antigen test, culture to confirm

**Treatment**
- in patients with HIV who have cryptococcal meningitis or severe pulmonary disease:
  - amphotericin B (+ flucytosine) is used in the first 2 wk for induction therapy; limited duration due to side effects
  - switch to fluconazole for at least 8 wk as consolidation therapy, then continue at lower dose for prolonged maintenance

**Candida albicans**

**Microbiology**
- yeast forms with pseudohyphae at 68°F/20°C and germ tube formation at 86°F/37°C

**Transmission**
- normal flora of skin, mouth, vagina, and GI tract
- risk factors for overgrowth
  - immunocompromised state (DM, corticosteroids)
  - ICU patients (broad-spectrum antibiotic use, central venous catheters, TPN)
  - obesity → maceration and moisture in intertriginous areas, pannus, under breasts

**Clinical Features**
- mucocutaneous
  - oral thrush, esophagitis (chest pain, odynophagia), vulvovaginitis (see *Gynecology*, GY24), balanitis, cutaneous (diaper rash, skin folds, folliculitis), chronic mucocutaneous
  - small satellite lesions beyond the margin of the rash
- invasive
  - candidemia, endophthalmitis, endocarditis, UTI (upper tract), hepatosplenic disease
**Aspergillus spp.**

**Microbiology**
- branching septate hyphae
- common species causing disease include *A. fumigatus, A. flavus*

**Transmission**
- ubiquitous in the air and the environment
- *Aspergillus* produces a toxin called aflatoxin that contaminates nuts, grains, and rice

**Clinical Features**
- allergic bronchopulmonary aspergillosis (ABPA)
  - IgE-mediated asthma-type reaction with dyspnea, high fever, and transient pulmonary infiltrates
  - occurs more frequently in patients with asthma and allergies
- aspergilloma (fungus ball)
  - ball of hyphae in a preexisting lung cavity
  - symptoms range from asymptomatic to massive hemoptysis
  - CXR: round opacity surrounded by a thin lucent rim of air, often in upper lobes (“air crescent” sign)
- invasive aspergillosis
  - associated with prolonged and persistent neutropenia or transplantation
  - pneumonia – most common
  - may disseminate to other organs: brain, skin
  - severe symptoms with fever, cough, dyspnea, caviation; fatal if not treated early and aggressively
  - CXR: local or diffuse infiltrates ± pulmonary infarction, pulmonary nodules with surrounding ground glass (“halo” sign)
- mycotoxicosis
  - aflatoxin produced by *A. flavus* (nuts, grains, rice)
  - results in liver necrosis and hepatocellular carcinoma

**Treatment Options**
- for invasive aspergillosis: voriconazole or amphotericin B
- surgical resection for aspergilloma
- corticosteroids ± itraconazole for ABPA

**Parasitic Infections**

**Protozoa – Intestinal/Genitourinal Infections**

**Entamoeba histolytica** (Amoebas)

**Transmission**
- reservoir: infected humans
- cysts by fecal-oral and food/waterborne transmission in areas of poor sanitation
- seen in immigrants, travelers, institutionalized individuals, Aboriginals, MSM

**Clinical Features**
- asymptomatic carriers
- amoebic dysentery
  - abdominal pain, cramping, colitis, dysentery, low grade fever with bloody diarrhea secondary to local tissue destruction and ulceration of large intestine
- amoebic abscesses
  - most common in liver (hematologic spread); presents with RUQ pain, weight loss, fever, hepatomegaly
- can also occur in lungs and brain
Investigations
- serology, fecal/serum antigen testing, stool exam (for cysts and trophozoites), colon biopsy
- E. histolytica indistinguishable microscopically from the non-pathogen E. dispar (distinguish by specific stool antigen detection)

Treatment and Prevention
- metronidazole
- for invasive disease or cyst elimination: follow with iodoquinol or paromomycin
- aspiration of hepatic abscess if risk of cyst rupture, poor response to medical therapy, or diagnostic uncertainty
- asymptomatic cyst: iodoquinol or paromomycin alone
- good personal hygiene, purification of water supply by boiling, filtration (not chlorination)

**Giardia lamblia**

Transmission
- reservoir: infected humans and other mammals
- food/waterborne (especially in the Rockies) and fecal-oral transmission of infectious cysts
- risk factors: travel, camping, institutions, day care centers, MSM

Clinical Features
- giardiasis (“beaver fever”)
  - symptoms vary from asymptomatic to self-limited mild watery diarrhea to malabsorption syndrome (chronic giardiasis where the parasite coats small intestine and thus prevents fat absorption)
  - nausea, malaise, abdominal cramps, bloating, flatulence, fatigue, weight loss, steatorrhea
  - no hematochezia (no invasion into intestinal wall), no mucus in stool

Investigations
- multiple stool samples (daily x 3 d) for microscopy, stool antigen used occasionally
- occasionally small bowel aspirate or biopsy

Treatment and Prevention
- metronidazole, nitazoxanide if symptomatic
- good personal hygiene and sanitation, water purification (iodine better than chlorination), outbreak investigation

**Trichomonas vaginalis**

Transmission
- sexual contact

Clinical Features
- often asymptomatic (10-50%), especially males (occasionally urethritis, prostatitis)
- trichomonas vaginitis (see Gynecology, GY25)
  - vaginal discharge (profuse, malodorous, yellow-green or gray, frothy), pruritus, dysuria, dyspareunia

Investigations
- wet mount (motile parasites), antigen detection, culture
- urine PCR to detect in males

Treatment
- metronidazole for patient and partner(s)

**Cryptosporidium spp.**

Transmission
- reservoir: infected humans and a wide variety of young animals
- fecal-oral transmission by ingestion of cysts, waterborne
- risk factors: summer and fall, young children (day care), MSM, contact with farm animals, immunocompromise, immune reconstitution

Clinical Features
- range from self-limited watery diarrhea (immunocompetent) to chronic, severe, non-bloody diarrhea with N/V, abdominal pain, and anorexia resulting in weight loss and death (immunocompromised)
Investigations
- modified acid-fast stain of stool specimen, microscopic identification of oocysts in stool or tissue, stool antigen detection by direct fluorescent antibody

Treatment and Prevention
- supportive care
- in HIV, try HAART to restore immunity; if fails, try nitazoxanide
- good personal hygiene, water filtration

Blood and Tissue Infections

Plasmodium spp. (Malaria)

Microbiology
- species include: P. falciparum (most common and most lethal), P. vivax, P. ovale, P. malariae, P. knowlesi (new species isolated from primates in Malaysia, potentially fatal)
- complex life cycle: human host for asexual reproduction and mosquito for sexual reproduction
- sporozoite from mosquitoes infect liver cells in which parasites multiply and are released as merozoites which infect RBCs causing disease
- P. ovale and P. vivax can produce dormant hypnozoites in the liver that may cause relapsing malarial attacks by reactivating (entering the erythrocytic cycle) after many months

Transmission
- reservoir: infected human
- transmission by the night-biting female Anopheles mosquito, vertical transmission, and blood transfusion
- occurs in tropical/subtropical regions (sub-Saharan Africa, Oceania, South Asia, Central America, Southeast Asia, South America)

Clinical Features
- flu-like prodrome
- paroxysms of high spiking fever and shaking chills (due to synchronous systemic lysis of RBCs)
  - lasts several hours
  - P. falciparum and P. ovale: chills and fever q48h but can be variable
  - P. malariae: chills and fever q72h but can be variable
- P. falciparum: less predictable fever interval, can be highly variable (>90% ill within 30 d)
- abdominal pain, diarrhea, myalgia, H/A, and cough
- hepatosplenomegaly and thrombocytopenia without leukocytosis

Complications
- P. falciparum: CNS involvement (cerebral malaria = seizures and coma), severe anemia, acute renal failure, ARDS, primarily responsible for fatal disease
- P. knowlesi, and rarely P. vivax can be fatal

Investigations
- microscopy: blood smear q12-24h (x3) to rule out infection
  - thick smear (Giemsa stain) for presence of organisms
  - thin smear (Giemsa stain) for species identification and quantification of parasites
- rapid antigen detection tests

Treatment and Prevention
- P. vivax, P. ovale: chloroquine (and primaquine to eradicate liver forms)
- P. vivax, chloroquine resistant: primaquine with quinine and doxycycline or tetracycline or mefloquine
- P. malariae, P. knowlesi: chloroquine
- P. falciparum: most areas of the world show chloroquine resistance – check local resistance patterns
  - artemisinin combination therapy (e.g. artesunate + doxycycline or clindamycin or atovaquone/proguanil)
  - atovaquone/proguanil combination (Malarone®)
  - quinine plus doxycycline, tetracycline, or clindamycin
  - mefloquine and artesinin resistance increasing in southeast Asia (check local resistance)
- prevention with antimalarial prophylaxis, covering exposed skin, bed nets, insect repellent

Trypanosoma cruzi

Transmission
- found in Mexico, South America, and Central America
- transmission by Reduviid insect vector ("Kissing Bug"), which defecates on skin and trypomastigotes in the stool are rubbed into bite site by host
also transmitted via placental transfer, organ donation, blood transfusion, and ingestion of contaminated food containing Reduviid insects (especially cane juice)

Clinical Features
- American trypanosomiasis (Chagas disease)
  - acute: usually asymptomatic, local swelling at site of inoculation (“Romana’s sign”; usually around one eye) with variable fever, lymphadenopathy, cardiomegaly, and hepatosplenomegaly
  - intermediate phase: asymptomatic but increasing levels of parasite and antibody in blood; most infected persons remain in this phase
  - chronic: can lead to chronic dilated cardiomyopathy, esophagomegaly, and megacolon 10-25 yr after acute infection in 30-40% of infected individuals

Investigations
- wet prep and Giemsa stain of thick and thin blood smear, serology, PCR

Treatment and Prevention
- acute: nifurtimox or benznidazole
- intermediate: increasing trend to treat as acute infection
- chronic: symptomatic therapy, surgery including heart transplant, or esophagectomy, colectomy, as necessary, may be a benefit to antiparasitic treatment
- insect control, bed nets

Toxoplasma gondii

Transmission
- acquired through exposure to cat feces (oocysts), ingestion of undercooked meat (tissue cysts), vertical transmission, organ transplantation, gardening without gloves, or whole blood transfusions

Clinical Features
- congenital
  - result of acute primary infection of mother during pregnancy (TORCH infection – see Obstetrics, OB19)
  - stillbirth (rare), chorioretinitis, blindness, seizures, severe developmental delay, microcephaly
  - initially asymptomatic infant may develop reactivation of chorioretinitis as adolescent or adult → blurred vision, scotoma, ocular pain, photophobia, epiphora, hearing loss, developmental delay
- acquired
  - usually asymptomatic or mononucleosis-like syndrome in immunocompetent patient
  - infection remains latent for life unless reactivation due to immunosuppression
- immunocompromised (most commonly AIDS with CD4 <200)
  - encephalitis with focal CNS lesions seen as single or multiple ring-enhancing masses on CT (H/A and focal neurological signs)
  - lymph node, liver, and spleen enlargement and pneumonitis
  - chorioretinitis

Investigations
- serology, CSF Wright-Giemsa stain, antigen or DNA detection (PCR); pathology provides definitive diagnosis
- immunocompromised patients: consider CT scan (ring-enhancing lesion in cortex or deep nuclei) and ophthalmologic examination
- negative serology in many AIDS patients (false negative due to decreased lymphocyte population)

Treatment and Prevention
- no treatment if: immunocompetent, not pregnant, no severe organ damage
- pregnancy: spiramycin to prevent transplacental transmission or pyrimethamine + sulfadiazine (add folinic acid), avoid undercooked meat and refrain from emptying cat litter boxes
- HIV: pyrimethamine + sulfadiazine (see Prophylaxis, ID29)
- eye disease, meningitis: corticosteroids
- proper hand hygiene, cook meat thoroughly to proper temperature

Figure 14. Life cycle of Toxoplasma gondii

**Trematodes/Flukes**

### Schistosoma spp.

#### Species
- *S. mansoni*, *S. hematobium*, *S. japonicum*

#### Transmission
- larvae (cercariae), released from snails, penetrate unbroken skin in infested fresh water
- adult worms live in terminal venules of bladder/bowel passing eggs into urine/stool
- eggs must reach fresh water to hatch; schistosomes cannot multiply in or pass between humans
  - more common in individuals from sub-Saharan Africa, South America, Asia, Caribbean, Eastern Mediterranean/North Africa

#### Clinical Features
- most asymptomatic; symptoms seen in travelers (nonimmune)
- Swimmer’s itch: pruritic skin rash at site of penetration (cercarial dermatitis)
- acute schistosomiasis (Katayama fever): hypersensitivity to migrating parasites (4-8 wk after infection)
  - fever, hives, H/A, weight loss, cough, abdominal pain, chronic diarrhea, eosinophilia

#### Complications of Chronic Infection
- *S. mansoni*, *S. japonicum*
  - worms in mesenteric vein, eggs in portal tracts of liver and bowel
  - heavy infections: intestinal polyps, portal and pulmonary HTN, splenomegaly (2° to portal HTN), hepatomegaly
- *S. hematobium*
  - worms in vesical plexus, eggs in distal ureter and bladder induce granulomas and fibrosis
  - hematuria and obstructive uropathy; associated with squamous cell bladder cancer
- neurologic complications: spinal cord neuroschistosomiasis (transverse myelitis), cerebral or cerebellar neuroschistosomiasis (increased ICP, focal CNS signs, seizures)
- pulmonary complications: granulomatous pulmonary endarteritis, pulmonary HTN, cor pulmonale; especially in patients with hepatosplenic involvement

*Figure 17. Life cycle of Schistosoma*
Investigations
- serology (high sensitivity and specificity), CBC (eosinophilia, anemia, thrombocytopenia)
- *S. mansoni*, *S. japonicum*: eggs in stool, liver U/S shows fibrosis, rectal biopsy
- *S. hematobium*: bladder biopsy, eggs in urine and occasionally stool, kidney and bladder U/S

Treatment and Prevention
- praziquantel
- add glucocorticoid if acute schistosomiasis or neurologic complications develop
- proper disposal of human fecal waste, molluscicide, avoidance of infested water
- do not swim in Lake Malawi

Ectoparasites
- scabies, lice
- see Dermatology, D26

Travel Medicine

General Travel Precautions
- vector-borne: long-sleeves, long pants, hats, repellents (containing permethrin) applied to clothes, belongings and bed nets, exposed skin
- food/water: avoid eating raw meats/seafood, uncooked vegetables, and milk/dairy products; drink only bottled beverages, chlorinated water, boiled water
- recreation: caution when swimming in schistosomiasis-endemic regions (Lake Malawi), fresh water rafting/kayaking, beaches that may contain human/animal waste products, near storm drains, after heavy rainfalls
- prophylaxis: malaria (chloroquine, mefloquine, atovaquone + proguanil, doxycycline), traveler’s diarrhea (bismuth salicylate)
- standard vaccines up to date (hepatitis B, MMR, tetanus/diphtheria, varicella, pertussis, polio)
- sexual transmission: HIV, HBV, syphilis, urinary tract infections (UTI), genital herpes
- travel vaccines: hepatitis A/B, Japanese encephalitis, typhoid fever, yellow fever, rabies, ETEC,
- prophylaxis: malaria (chloroquine, mefloquine, atovaquone + proguanil, doxycycline), traveler’s diarrhea (bismuth salicylate)
- recreation: caution when swimming in schistosomiasis-endemic regions (Lake Malawi), fresh water rafting/kayaking, beaches

Infectious Diseases to Consider
- sexually transmitted: HIV, HBV, syphilis, usual STDs
- zoonotic: rabies, *Bartonella bacilliformis* (Bartonellosis), *Rickettsia rickettsii* (Lyme Disease), *Leishmania* spp., *Brucella* spp., *Borreliosis*
- airborne: TB
- soil/water: schistosomiasis, strongyloidiasis, leptospirosis, cutaneous larva migrans, histoplasmosis, paracoccidioidomycosis

Fever in the Returned Traveler

Etiology
- commonly identified causes of fever in returning traveler
  - parasitic: malaria (20-30%), *Plasmodium* spp.
  - viral: non-specific mononucleosis-like syndrome (4-25%), dengue (5%), viral hepatitis (3%)
  - bacterial: typhoid from *Salmonella* spp. (2-7%), *Shigella* spp. (3%)
  - diverse group of causative pathogens: traveler’s diarrhea (10-20%), RTI (10-15%), UTI/STD (2-3%)
- febrile illness in travelers can be caused by routine infections that are common in non-travelers (e.g. URTI, UTI)
- less commonly, fever can be due to non-infectious causes: e.g. DVT, PE

History
- pre-travel preparation
- travel itinerary: when, where, why, what, how, who?
  - dates of travel (determine incubation period)
  - season of travel: wet or dry
  - destination: country, region (urban or rural), environment (jungle, desert, etc.)
  - purpose of trip

For up to date information on geographic and seasonal patterns of disease and travel advisories, check the website for the United States Centers for Disease Control and Prevention (wwwnc.cdc.gov/travel) or Foreign Affairs Canada (travel.gc.ca)
• persons visiting friends and family more likely to be exposed to local population and pathogens
  ▪ style of travel: lodgings, camping, adventure traveling
  ▪ local population: sick contacts
  ▪ transportation: use of animals
• exposure history
  ▪ street foods, untreated water: increased risk of traveler’s diarrhea, enteric fever
  ▪ uncooked meat/unpasteurized dairy: increased risk of parasitic infection
  ▪ body fluids (sexual contacts, tattoos, piercings, IVDU, other injections)
  ▪ increased risk of HBV, HCV, HIV, GC, C. trachomatis, syphilis
  ▪ animal/insect bites: increased risk of malaria, dengue, rickettsioses, rabies
• fever pattern
  ▪ incubation period: use the earliest and latest possible dates of exposure to narrow the differential diagnosis and exclude serious infections
    ▪ <21 d: consider malaria, typhoid fever, dengue fever, rickettsioses; exclude HBV, TB
    ▪ >21 d: consider malaria, TB; exclude dengue fever, travelers’ diarrhea, rickettsioses
  ▪ body systems affected: GI, respiratory, CNS, skin

### Investigations
• all travelers with fever should undergo the following tests
  ▪ blood work: CBC and differential, liver enzymes, electrolytes, creatinine, thick and thin blood smears x3 (for malaria), blood C&S
  ▪ urine: urinalysis, urine C&S
  ▪ special tests based on symptoms, exposure history, and geography
    ▪ stool: C&S, O&P
    ▪ CXR
    ▪ dengue serology for IgM

<td>Diagnosis uncertain after 3 d of investigation, including at least 2 d incubation of cultures</td>
<td>Diagnosis uncertain after 3 d of investigation, including at least 2 d incubation of cultures</td>
<td></td>
</tr>
</tbody>
</table>

#### Etiology of Classic FUO
- infectious causes (~30%)
  - TB: extra-pulmonary (most common), miliary, pulmonary (if pre-existing disease)
  - abscess: subphrenic, liver, splenic, pancreatic, perinephritic, diverticular, pelvis, psoas
  - osteomyelitis
  - bacterial endocarditis (culture negative)
  - uncommon: viral (CMV, EBV), fungal (histoplasmosis, cryptococcosis), parasitic (toxoplasmosis, leishmaniasis, amoebiasis, malaria)
- neoplastic causes (~20%)
  - most commonly lymphomas (especially non-Hodgkin’s) and leukemias, also multiple myeloma, myelodysplastic syndrome
  - solid tumors: RCC (most common), also breast, liver (hepatoma), colon, pancreas, or liver metastases
- collagen vascular diseases (~30%)
  - SLE, RA, rheumatic fever, vasculitis (temporal arteritis, PAN), JRA, Still’s disease
- miscellaneous (~20%)
  - drugs, factitious fever
  - sarcoidosis, granulomatous hepatitis, IBD
  - hereditary periodic fever syndromes (such as familial Mediterranean fever)
  - venous thromboembolic disease: PE, DVT
  - endocrine: thyroiditis, thyroid storm, adrenal insufficiency, pheochromocytoma
- unknown in 30-50% despite detailed workup

#### Approach to Classic FUO
- careful history: travel, environmental/occupational exposures, infectious contacts, medication history, immunizations, TB history, sexual history, past medical history, comprehensive review of systems (including symptoms that resolved before interview)
- thorough physical exam: fever pattern, rashes (skin, mucous membranes), murmurs, arthritis, lymphadenopathy, organomegaly
- initial investigations as appropriate
  - blood work: CBC and differential, electrolytes, BUN, Cr, calcium profile, LFTs, ESR, CRP, muscle enzymes, RF, ANA, serum protein electrophoresis (SPEP), blood smear
  - cultures: blood (x2 sets), urine, sputum, stool C&S, O&P, other fluids as appropriate
  - serology: HIV, monospot, CMV IgM
  - imaging: CXR, abdominal imaging
- if there are diagnostic clues from any of the above steps, proceed with directed exam, biopsies or invasive testing as required, followed by directed treatment once a diagnosis is established
- if no diagnosis with the above, consider empiric therapy vs. watchful waiting
  - without intervention: patients that remain undiagnosed despite extensive workup have good prognosis

#### Anti-Drugs that may Cause Fever:
- Anti-microbials (sulfonamides, penicillins, nitrofurantoin, antimalarials)
- Anti-hypertensives (hydralazine, methyldopa)
- Anti-epileptics (barbiturate, phenytoin)
- Anti-arrhythmics (quinine, propranolol)
- Anti-inflammatory (NSAIDs)
- Anti-thyroid

#### Causes of Nosocomial FUO
- B, C, D, E
- Bacterial and fungal infections of respiratory tract and surgical sites
- Catheters (intravascular and urinary)
- Drugs
- Emboli
Infections in the Immunocompromised Host

- immunocompromised hosts have increased susceptibility to infections from pathogens that are typically low virulence, commensal, or latent
- type of immunosuppression predicts probable spectrum of agents

Factors that Compromise the Immune System

- general: age (very young or elderly), malnutrition
- immune disease: HIV/AIDS, malignancies, asplenia (functional or anatomic), hypogammaglobulinemia, neutropenia
- DM
- iatrogenic: corticosteroids, chemotherapy, radiation treatment, anti-TNF therapy, other immunosuppressive drugs (e.g. in transplant patients)

Factors that Compromise the Immune System Table 30. Types of Immunocompromise

</tr>
<tr>
<td>Neutrophil Function</td>
<td>Myelodyplasia, paroxysmal nocturnal hemoglobinuria, radiation, cytotoxic drug therapy, C3 or C5 deficiencies, chronic granulomatous disease</td>
<td>Catalase-producing organisms (Staphylococcus, Serratia, Nocardia, Aspergillus)</td>
</tr>
</tbody>
</table>

Febrile Neutropenia

Definition
- fever (≥101°F/38.3°C or ≥100.4°F/38.0°C for ≥1 h) and one of:
  - ANC <0.5 OR
  - ANC <1.0 but trending down to 0.5

Pathophysiology
- decreased neutrophil production
  - marrow: infection, aplastic/myelophthisic anemia, leukemia, lymphoma, myelodyplastic syndromes
  - iatrogenic: cancer chemotherapy, radiation, drugs
  - deficiencies: vitamin B12, folate
- increased peripheral neutrophil destruction
  - autoimmune: Felty’s syndrome, SLE, antineutrophil antibodies
  - splenic sequestration

Epidemiology/Etiology
- most common life-threatening complication of cancer therapy
- 8 cases per 1,000 cancer patients per year in the U.S.
- causative organism identified only 1/3 of the time
- GN (especially Pseudomonas) historically most common
- GP more common now
- fungal superinfection if neutropenia prolonged or if concurrent antibiotic use (especially Candida, Aspergillus)

Investigations
- examine for potential sites of infection: mucositis and line infections are most common
- do NOT perform DRE; examine perianal region
- blood C&S (x2 sets), urine C&S, culture all indwelling catheter ports, ± sputum C&S and NP swab for respiratory viruses
- CBC and differential, Cr, BUN, electrolytes, AST/ALT, total bilirubin

Treatment
- most hospitals have their own specific protocol; one example is presented below
Infections in Solid Organ Transplant Recipients

- infection is a leading cause of early morbidity/mortality in transplant recipients
- infection depends on degree of immunosuppression
- common infections <1 mo post-transplant
  - bacterial infection of wound/lines/lungs, herpetic stomatitis
- common infections >1 mo post-transplant
  - viral (especially CMV, EBV, VZV)
  - fungal (especially Aspergillus, Cryptococcus, P. jiroveci)
  - protozoan (especially Toxoplasma)
  - unusual bacterial/mycobacterial infections (especially TB, Nocardia, Listeria)

Prophylactic Vaccinations Given Before Transplant
- to all transplant patients: D'TaP, pneumococcal, influenza, hepatitis A and B vaccines
- if low titer or poor documentation: MMR, polio, varicella vaccination (with booster 4-8 wk later)

Immune Reconstitution Syndrome

Definition
- a harmful inflammatory response directed against a previously acquired infection following a recovery of the immune system

Etiology
- paradoxical worsening of a successfully or partially treated opportunistic infection
- new onset response to a previously unidentified opportunistic infection
- the majority of cases are in HIV/AIDS or immunosuppressed patients starting antiretroviral therapy or discontinuing immunosuppressive therapy; sudden recovery from an immunosuppressive state towards a pro-inflammatory state directed towards subclinical infection results in fever and inflammation
- can occur in response to multiple infections
  - Mycobacteria (tuberculosis, avium complex)
  - Cryptococcus
  - Pneumocystis
  - Toxoplasma
  - HBV and HCV
  - Herpes viruses (VZV reactivation, HSV, CMV)
  - JC virus (progressive multifocal leukoencephalopathy)
  - Molluscum contagiosum
clinical features are dependent on the type and location of the pre-existing infection
thought to be worse with quick increase in CD4 count and with lower pre-treatment CD4 count
non-HIV conditions with documented IRS: solid organ transplant recipients, post-partum
women, neutropenic patients, anti-TNF therapy

Epidemiology
- in HIV patients starting HAART, IRS reported to affect ~10%

Investigations
- diagnosis of exclusion
- rule out drug reaction, patient non-adherence, drug resistance

Treatment
- continue HAART therapy in HIV patients with mild-moderate symptoms, but consider
discontinuation if symptoms are life-threatening or potentially irreversible
- treat underlying infection; initiate treatment for some infections prior to HAART initiation
- consider starting corticosteroids/NSAIDs to decrease inflammatory response

A Simplified Look at Antibiotics

1. Penicillins (most Streptococcus, N. meningitidis, many oral anaerobes except B. fragilis)

2. Cephalosporins (PO/IV)
   - 1st generation: cephalexin/cefazolin (mostly GP, some GN)
   - 2nd generation: cefuroxime/cefprozil (some GP and some GN, *anaerobes)
   - 3rd generation: cefixime/cefotaxime, ceftriaxone (good Streptococcal coverage, mostly GN) and
ceftazidime (no GP, mostly GN, Pseudomonas)
   - 4th generation: */cefepime (most GP, most GN, Pseudomonas)

3. Aminoglycosides (GN aerobic bacilli)
   - gentamicin
   - tobramycin
   - amikacin

4. Macrolides (GP, Haemophilus, and atypical bacteria [Legionella, Chlamydia, Mycoplasma])
   - erythromycin
   - clarithromycin
   - azithromycin

5. Fluoroquinolones (GN – although resistance becoming a huge problem)
   - ciprofloxacin (+ Pseudomonas)
   - norfloxacin (for UTI only)
   - respiratory fluoroquinolones (some GP, GN, "atypicals", Legionella, Mycoplasma, Chlamydia)
     - levofloxacin
     - moxifloxacin (+ anaerobes)

6. Carbapenems (broad coverage: GP, GN, and anaerobes)
   - imipenem (+ Pseudomonas)
   - meropenem (+ Pseudomonas)
   - ertapenem
7. Others
- doxycycline/tetracycline (GP, syphilis, Chlamyphila, Rickettsia, Mycoplasma)
- vancomycin (all GP and *C. difficile* – the oral form)
- linezolid (for resistant GP infections)
- clindamycin (most GP, GN anaerobes)
- TMP/SMX (most *S. aureus* including: MRSA, GN aerobes, *Pneumocystis*)
- nitrofurantoin (GN bacilli, *S. saprophyticus*, *Enterococcus*)
- metronidazole (anaerobes including: *C. difficile*, *Trichomonas*, *Entamoeba*)
- treatment for *C. difficile*: metronidazole OR oral vancomycin; consider both in serious infection

**Antimicrobials**

**Antibiotics**

- empiric antibiotic therapy
  - choose antibiotic(s) to cover for most likely and lethal organisms for the type of infection prior to obtaining laboratory results (usually reserved for serious infections)
  - adjust antibiotic(s) based on C&S
    - if causative organism identified, use antibiotic to which organism is sensitive
    - if causative organism not identified, re-evaluate need for ongoing antimicrobial therapy (and continue with empiric antibiotic(s) if indicated)

**Reasons for Combination Therapy**
- Polymicrobial infection
- Empiric therapy pending culture results
- Synergy for difficult to treat pathogens (e.g. *Enterococcus* spp. causing endocarditis)
- To prevent emergence of resistance

**Bactericidal Antibiotics**
- Vancomycin
- Fluoroquinolones
- Cephalosporins
- Carbapenems
- Glycopeptides

**Bacteriostatic Antibiotics**
- Erythromycin (and other macrolides)
- Clindamycin
- Sulfamethoxazole
- Trimethoprim
- Tetracyclines
- Chloramphenicol

**Figure 20. Mechanism of action of antibiotics**

## Imaging Modalities

### X-Ray Imaging
- x-rays, or Röentgen rays, are a form of electromagnetic energy of short wavelength
- as x-ray photons traverse matter, they can be absorbed (a process known as "attenuation") and/or scattered
- the density of a structure determines its ability to attenuate or "weaken" the x-ray beam
  - air < fat < water < bone < metal
- structures that have high attenuation (e.g. bone) appear white on the resulting images

### Plain Films
- x-rays pass through the patient and interact with a detection device to produce a 2-dimensional projection image
- structures closer to the film appear sharper and less magnified
- contraindications: pregnancy (relative)
- advantages: inexpensive, non-invasive, readily available
- disadvantages: radiation exposure, generally poor at distinguishing soft tissues

### Fluoroscopy
- used for guiding angiographic and interventional procedures, in contrast examinations of the GI tract, and in the OR for certain surgical procedures (e.g. orthopedic, urological)
- on the fluoroscopic image, black and white are reversed so that bone and contrast agents appear dark and radiolucent structures appear light
- advantages: continuous x-rays allow real-time visualization
- disadvantages: increased radiation dose; however, the use of pulsed fluoroscopy has reduced fluoroscopy time by 76% and radiation dose by 64% as compared with continuous fluoroscopy

### Computed Tomography
- x-ray beam opposite a detector moves in a continuous 360 degree arc as patient is advanced through scanner, higher cost, and less available than plain film
- allows 3D reconstruction, CTA is less invasive than conventional angiography
- disadvantages: high radiation exposure, IV contrast injection, anxiety of patient when going through scanner, higher cost, and less available than plain film

### Ultrasound
- high frequency sound waves are transmitted from a transducer and passed through tissues; reflections of the sound waves are picked up by the transducer and transformed into images
- reflection (or “echo”) occurs when the sound waves pass through tissue interfaces of different acoustic densities
- structures are described based on their echogenicity; hyperechoic structures appear bright (ultrasound reflected) whereas hypoechoic structures appear dark (U/S waves not reflected back but pass through)
- higher U/S frequencies result in greater resolution but greater attenuation (i.e. deeper structures more difficult to visualize)
- artifacts: acoustic shadowing refers to the echo-free area located behind an interface that strongly reflects (e.g. tissue/air) or absorbs (e.g. tissue/bone) sound waves; enhancement refers to the increase in reflection amplitude (i.e. increased brightness) from objects that lie below a weakly attenuating structure (e.g. cyst)
- Doppler: determines the velocity of blood flowing past the transducer based on the Doppler effect
- Duplex scan: Doppler + visual images
- advantages: relatively low cost, non-invasive, no radiation, real time imaging, may be used for guided biopsies, many different imaging planes ( axial, sagittal), determines cystic vs. solid
- disadvantages: highly operator-dependent, air in bowel may prevent imaging of midline structures in the abdomen, may be limited by patient habitus

### Typical Effective Doses from Diagnostic Medical Exposures (in adults) *

Magnetic Resonance Imaging

- non-invasive technique that does not use ionizing radiation
- able to produce images in virtually any plane
- patient is placed in a magnetic field; protons (H⁺) align themselves along the plane of magnetization due to intrinsic polarity. A pulsed radiofrequency beam is subsequently turned on which deflects all the protons off their aligned axes due to absorption of energy from the radiofrequency beam. When the radiofrequency beam is turned off, the protons return to their pre-excitation axis, giving off the energy they absorbed. This energy is measured with a detector and interpreted by a computer to generate MR images
- the MR image reflects the signal intensity picked up by the receiver. This signal intensity is dependent on:
  1. hydrogen density: tissues with low hydrogen density (e.g. cortical bone, lung) generate little to no MR signal compared to tissues with high hydrogen density (e.g. water)
  2. magnetic relaxation times (T1 and T2): reflect quantitative alterations in MR signal strength due to intrinsic properties of the tissue and its surrounding chemical and physical environment

Table 1. Differences Between Diffusion, T1- and T2-Weighted MR Imaging

<table>
<thead>
<tr>
<th>Imaging Techniques</th>
<th>Contrast Enhancements</th>
<th>Main Application</th>
<th>Advantages</th>
</tr>
</thead>
<tbody>
<tr>
<td>Diffusion Weighted Imaging</td>
<td>Contrast dependent on the molecular motion of water Decreased diffusion is hypointense (dark), whereas increased diffusion is hyperintense (bright)</td>
<td>Neuroradiology</td>
<td>Sensitive for detection of acute ischemic stroke and differentiating an acute stroke from other neurologic pathologies Acute infarction appears hyperintense Absence collections also show restricted diffusion</td>
</tr>
<tr>
<td>T1-Weighted</td>
<td>Fluid is hypointense (dark) and fat is hyperintense (bright)</td>
<td>Body soft tissues</td>
<td>Often considered an anatomic scan since they provide a reference for functional imaging</td>
</tr>
<tr>
<td>T2-Weighted</td>
<td>Fluid is hyperintense (bright) and fat is hypointense (dark)</td>
<td>Body soft tissues</td>
<td>Often considered a pathologic scan since they will highlight edematous areas associated with certain pathologies</td>
</tr>
</tbody>
</table>

Positron Emission Tomography Scans

- non-invasive technique that involves exposure to ionizing radiation (~7 mSv)
- nuclear medicine imaging technique that produces images of functional processes in the body
- current generation models integrate PET and CT technologies into a single imaging device (PET-CT) that collects both anatomic and functional information during a single acquisition
- positron-producing radioisotope, such as 18FDG is chemically incorporated into a metabolically active molecule (e.g. glucose), injected into patient, which travels to target organ, accumulates in tissues of interest, and as radioactive substance begins to decay, gamma rays are produced which are detected by PET scanner
- contraindications: pregnancy
- advantages: shows metabolism and physiology of tissues (not only anatomic), in oncology allows diagnosis, staging, restaging, has predictive and prognostic value, can evaluate cardiac viability
- disadvantages: cost, ionizing radiation

Contrast Enhancement

Table 2. Contrast Agents

<table>
<thead>
<tr>
<th>Imaging Modality</th>
<th>Types</th>
<th>Advantages</th>
<th>Disadvantages</th>
<th>Contraindications</th>
</tr>
</thead>
<tbody>
<tr>
<td>X-Ray/CT</td>
<td>1. Barium (oral or rectal)</td>
<td>Radiopaque substance which helps to delineate intraluminal anatomy, may demonstrate patency, lumen integrity, or large filling defects</td>
<td>Risk of nephrogenic systemic fibrosis in patients with end-stage renal disease</td>
<td>Previous adverse reaction to contrast; barium enema is contraindicated in toxic megacolon, acute colitis, and suspected perforation</td>
</tr>
<tr>
<td></td>
<td>2. Iodine (IV injection)</td>
<td>Delineates intraluminal anatomy, may demonstrate patency, lumen integrity, or large filling defects; under fluoroscopy, may also give information on function of an organ</td>
<td></td>
<td>Previous adverse reaction to contrast, renal failure, DM, pregnancy, multiple myeloma, severe heart failure and dehydration eGFR &lt;60 may require preventative measures and follow up</td>
</tr>
<tr>
<td>MRI</td>
<td>Gadolinium-Chelates</td>
<td>Shortens T1 relaxation time, thereby increasing signal intensity in T1-weighted sequences; gadolinium has some effect on T2-relaxation time; highlights highly vascular structures (e.g. tumors)</td>
<td>Risk of nephrogenic systemic fibrosis in patients with end-stage renal disease</td>
<td>Previous adverse reaction to contrast or if end-stage renal disease (relative contraindication)</td>
</tr>
<tr>
<td></td>
<td>(IV injection)</td>

Chest Imaging

Chest X-Ray

Standard Views
- PA: anterior chest against film plate to minimize magnification of the heart size
- lateral: better visualization of retrocardiac space and thoracic spine (more sensitive at picking up pleural effusions)
  - helps localize lesions when combined with PA view
- AP: for bedridden patients (generally a lower quality film than PA because of enlarged cardiac silhouette)
- lateral decubitus: to assess for pleural effusion and pneumothorax in bedridden patients; however, POCUS can also be utilized for both these purposes
- lordotic: angled beam allowing better visualization of apices normally obscured by the clavicles and anterior ribs

Figure 1. CXR views

Approach to CXR

Basics
- ID: patient name, MRN, sex, age
- date of exam
- markers: right and/or left
- technique: view (e.g. PA, AP, lateral), supine or erect
- indications for the study
- comparison: date of previous study for comparison (if available)
- quality of film: inspiration (6th anterior and 10th posterior ribs should be visible), penetration (thoracic spine should be visible) and rotation (clavicles vs. spinous process)

Analysis
- tubes and lines: check position and be alert for pneumothorax or pneumomediastinum
- soft tissues: neck, axillae, pectoral muscles, breasts/nipples, chest wall
  - nipple markers can help identify nipples (may mimic lung nodules)
  - amount of soft tissue, presence of masses and air (subcutaneous emphysema)
- abdomen (see Abdominal Imaging, MI10)
  - free air under the diaphragm, air-fluid levels, distention in small and large bowels
  - herniation of abdominal contents (i.e. diaphragmatic hernia)
- bones: C-spine, thoracic spine, shoulders, ribs, sternum, clavicles
  - lytic and blastic lesions and fractures
- mediastinum: trachea, heart, great vessels
  - cardiomegaly (cardiothoracic ratio >0.5), tracheal shift, tortuous aorta, widened mediastinum
- hila: pulmonary vessels, mainstem and segmental bronchi, lymph nodes
- lungs: lung parenchyma, pleura, diaphragm
  - comment on abnormal lung opacity, pleural effusions or thickening
  - right hemidiaphragm usually higher than left due to liver
  - right vs. left hemidiaphragm can be discerned on lateral CXR due to heart resting directly on left hemidiaphragm

Sodium Bicarbonate Plus N-Acetylcysteine Prophylaxis: A Meta-Analysis
J Am Coll Cardiol Intv 2009;2:1116-1124
Study: A meta-analysis of 10 RCTs.
Objective: To compare N-acetylcysteine (NAC) + sodium bicarbonate (NaHCO$_3$) to NAC + normal saline hydration in prevention of acute kidney injury (AKI) from IV contrast.
Patients: Those receiving IV contrast for various indications (PCI, angiography, catheterization)
Results: Combination treatment of NAC with intravenous NaHCO$_3$ reduced contrast-induced AKI by 35% (relative risk: 0.65; 95% confidence interval: 0.40-1.05). However, the combination of N-acetylcysteine plus NaHCO$_3$ did not significantly reduce renal failure requiring dialysis.
Conclusion: Combination prophylaxis should be considered for all high-risk patients (emergency cases or patients with chronic kidney disease).
**Anatomy**

**Localizing Lesions for Parenchymal Lung Disease**

- **silhouette sign**: loss of normal interfaces due to lung pathology (consolidation, atelectasis, mass), which can be used to localize disease in specific lung segments; note that pleural or mediastinal disease can also produce the silhouette sign)

- **spine sign**: on lateral films, vertebral bodies should appear progressively radiolucent as one moves down the thoracic vertebral column; if they appear more radiopaque, it is an indication of pathology (e.g. consolidation in overlying left lower lobe)

- **air bronchogram**: branching pattern of air filled bronchi on a background of fluid filled airspaces

Computed Tomography Chest

**Approach to CT Chest**
- **soft tissue window**
  - thyroid, chest wall, pleura
  - heart: chambers, coronary artery calcifications, pericardium
  - vessels: aorta, pulmonary artery, smaller vasculature
  - lymph nodes: mediastinal, axillary
- **bone window**
  - vertebrae, sternum, manubrium, ribs: fractures, lytic lesions, sclerosis
- **lung window**
  - trachea: patency, secretions
  - bronchial trees: anatomic variants, mucus plugs, airway collapse
  - lung parenchyma: fissures, nodules, fibrosis/interstitial changes
  - pleural space: effusions

**Lung Abnormalities**

**Atelectasis**
- pathogenesis: collapse of alveoli due to restricted breathing, blockage of bronchi, external compression, or poor surfactant
- findings
  - increased opacity of involved segment/lobe, vascular crowding, silhouette sign, air bronchograms
  - volume loss: fissure deviation, hilar/mediastinal displacement, diaphragm elevation
  - compensatory hyperinflation of remaining normal lung
- differential diagnosis
  - obstructive (most common): air distal to obstruction is reabsorbed causing alveolar collapse
    - post-surgical, endobronchial lesion, foreign body, inflammation (granulomatous infections, pneumoconiosis, sarcoidosis, radiation injury) or mucous plug (cystic fibrosis)
  - compressive
    - tumor, bulla, effusion, enlarged heart, lymphadenopathy
  - traction (cicatrization): due to scarring, which distorts alveoli and contracts the lung
  - adhesive: due to lack of surfactant
    - hyaline membrane disease, prematurity
  - passive (relaxation): a result of air or fluid in the pleural space
    - pleural effusion, pneumothorax
- management: in the absence of a known etiology, persisting atelectasis must be investigated (i.e. CT thorax) to rule out a bronchogenic carcinoma

**Consolidation**
- pathogenesis: fluid (water, blood), inflammatory exudates, protein, or tumor in alveoli
- findings
  - air bronchograms: lucent branching bronchi visible through opacification
  - airspace nodules: fluffy, patchy, poorly defined margins with later tendency to coalesce, may take on lobar or segmental distribution
  - silhouette sign
• differential diagnosis
  • fluid: pulmonary edema, blood (trauma, vasculitis, bleeding disorder, pulmonary infarct)
  • inflammatory exudates: bacterial infections, TB, allergic hypersensitivity alveolitis, BOOP, allergic bronchopulmonary aspergillosis, aspiration, sarcoidosis
  • protein: pulmonary alveolar proteinosis
  • tumor: bronchoalveolar carcinoma, lymphoma
• management: varies depending on the pattern of consolidation, which can suggest different etiologies; should also be done in the context of clinical picture

**Interstitial Disease**

• pathogenesis: pathological process involving the interlobular connective tissue (i.e. “scaffolding of the lung”)

• findings
  • linear: fine lines caused by thickened connective tissue septae
    • Kerley A: long thin lines in upper lobes
    • Kerley B: short horizontal lines extending from lateral lung margin
    • Kerley C: diffuse linear pattern throughout lung
  • nodular: 1-5 mm well-defined nodules distributed evenly throughout lung
    • seen in malignancy, pneumonia and granulomatous disease (e.g. sarcoidosis, miliary TB)
  • reticular (honeycomb): parenchyma replaced by thin-walled cysts suggesting extensive destruction of pulmonary tissue and fibrosis
    • seen in IPF, asbestosis, and CVD
    • watch for pneumothorax as a complication
  • reticulonodular: combination of reticular and nodular patterns
    • may also see signs of airspace disease (atelectasis, consolidation)

• differential diagnosis
  • occupational/environmental exposure
    • inorganic: asbestosis, coal miner’s pneumoconiosis, silicosis, berylliosis, talc pneumoconiosis
    • organic: hypersensitivity pneumonitis, bird fancier’s lung, farmer’s lung (moldy hay), and other organic dust
  • autoimmune: CVD (e.g. rheumatoid arthritis, scleroderma, SLE, polymyositis, mixed connective tissue disease), IBD, celiac disease, vasculitis
  • drug-related: antibiotics (cephalosporins, nitrofurantoin), NSAIDs, phenytoin, carbamazepine, fluoxetine, amiodarone, chemotherapy (e.g. methotrexate), heroin, cocaine, methadone
  • infections: non-tuberculous mycobacteria, certain fungal infections
  • idiopathic: hypersensitivity pneumonitis, IPF, BOOP
  • for Causes of Interstitial Lung Disease Classified by Distribution, see Respirology, R13

• management: high resolution CT thorax and biopsy

**Pulmonary Nodule**

• findings: round opacity ± silhouette sign
  • note: do not mistake nipple shadows for nodules; if in doubt, repeat CXR with nipple markers

• differential diagnosis
  • extrapulmonary density: nipple, skin lesion, electrode, pleural mass, bony lesion
  • solitary nodule
    • tumor: carcinoma, hamartoma, metastasis, bronchial adenoma
    • inflammation: histoplasmoma, tuberculosis, coccidioidomycosis
    • vascular: AV fistula, pulmonary varix (dilated pulmonary vein), infarct, embolism
    • multiple nodules: metastases, abscess, granulomatous lung disease (TB, fungal, sarcoïd, rheumatoid nodules, silicosis, GPA)
  • management: clinical information and CT appearance determine level of suspicion of malignancy
    • if high probability of malignancy, invasive testing (fine needle aspiration, transbronchial/ transthoracic biopsy) is indicated
    • if low probability of malignancy, repeat CXR or CT in 1-3 mo and then every 6 mo for 2 yr; if no change, then >99% chance benign

**DDx of Interstitial Lung Disease**

**FASSTEN (upper lung disease)**

- Farmer’s lung (hypersensitivity pneumonitis)
- Asbestosis
- Silicosis
- TB
- Eosinophilic granuloma (Langerhans cell histiocytosis)
- Neurofibromatosis
- BAD RASH (lower lung disease)
- BOOP
- Asbestos
- Drugs (nitrofurantoin, hydralazine, isoniazid, amiodarone, many chemotherapy drugs)
- Rheumatological disease
- Aspiration
- Sarcoidosis
- Harman Rich (IPF) and diastolic pulmonary fibrosis

**DDx for Cavitating Lung Nodule**

**WEIRD HOLES**

- GPA (Wegener’s)
- Embolic (pulmonary, septic)
- Infection (anaerobes, pneumococci, TB)
- Rheumatoid (necrobiotic nodules)
- Developmental cysts (sequestration)
- Histiocytosis
- Onco logical
- Lymphangioleiomyomatosis
- Environmental, occupational
- Sarcodeiosis

**Pulmonary Nodule Follow-Up**

Always check for previous CXR if available (lesions such as granuloma could be stable for many yr)
Reliable predictors of benign disease on CXR: 1) benign calcifications 2) absence of growth over 2 yr

**Pulmonary Vascular Abnormalities**

**Pulmonary Edema**
- pathogenesis: fluid accumulation in the airspaces of the lungs
- findings
  - vascular redistribution/enlargement, cephalization, pleural effusion, cardiomegaly (may be present in cardiac edema and fluid overloaded states)
  - fluid initially collects in interstitium
    - loss of definition of pulmonary vasculature
    - peribronchial cuffing
    - Kerley B lines
    - reticulonodular pattern
    - thickening of interlobar fissures
  - as pulmonary edema progresses, fluid begins to collect in alveoli causing diffuse air space disease often in a “bat wing” or “butterfly” pattern in perihilar regions with tendency to spare the outermost lung fields
- differential diagnosis: cardiogenic (e.g. CHF), renal failure, volume overload, non-cardiogenic (e.g. ARDS)

**Pulmonary Embolism**
- pathogenesis: arterial blockage in the lungs due to emboli from pelvic or leg veins, rarely from PICC lines, ports, or air, fat, or amniotic fluid (difficult to diagnose on imaging except by combination of clinical history and CXR and CT findings of ARDS)
- findings
  - CXR: Westermark sign (localized pulmonary oligemia), Hampton’s hump (triangular peripheral infarct), enlarged right ventricle and right atrium, atelectasis, pleural effusion, and rarely pulmonary edema
  - definitive imaging study: CT pulmonary angiography to look for filling defect in contrast-filled pulmonary arteries (emboli can be seen up to 4th order arterial branching)
  - V/Q scan: not a diagnostic study

**Pleural Abnormalities**

**Pleural Effusion**

</tbody>
</table>

- a horizontal fluid level is seen only in a hydropneumothorax (i.e. both fluid and air within pleural cavity)
- effusion may exert mass effect, shift trachea and mediastinum to opposite side, or cause atelectasis of adjacent lung
- U/S is superior to plain film for detection of small effusions and may also aid in thoracentesis, and POCUS is now standard of care in acute situations
- fluid level >1 cm on lateral decubitus film is indication to perform thoracentesis

**Pneumothorax**
- pathogenesis: gas/air accumulation within the pleural space resulting in separation of the lung from the chest wall
• findings
  ▪ upright chest film allows visualization of visceral pleura as curvilinear line paralleling chest wall, separating partially collapsed lung from pleural air
  ▪ more obvious on expiratory (increased contrast between lung and air) or lateral decubitus films (air collects superiorly)
  ▪ more difficult to detect on supine film; look for the “deep (costophrenic) sulcus” sign, “double diaphragm” sign (dome and anterior portions of diaphragm outlined by lung and pleural air, respectively), hyperlucent hemithorax, sharpening of adjacent mediastinal structures
  ▪ mediastinal shift may occur if tension pneumothorax
  ▪ differential diagnosis: spontaneous (tall and thin males, smokers), iatrogenic (lung biopsy, ventilation, CVP line insertion), trauma (associated with rib fractures), emphysema, malignancy, honeycomb lung
  ▪ management: needle decompression or chest tube insertion, repeat CXR to ensure resolution

Asbestos
• asbestos exposure may cause various pleural abnormalities including benign plaques (most common) that may calcify, diffuse pleural fibrosis, effusion, and malignant mesothelioma

Mediastinal Abnormalities

Mediastinal Mass
• the mediastinum is divided into four compartments; this provides an approach to the differential diagnosis of a mediastinal mass
• anterior (anterior border formed by the sternum and posterior border by the heart and great vessels)
  ▪ 4 Ts: see sidebar
  ▪ cardiophrenic angle mass differential: thymic cyst, epicardial fat pad, foramen of Morgagni hernia
• middle (extending behind anterior mediastinum to a line 1 cm posterior to the anterior border of the thoracic vertebral bodies)
  ▪ esophageal carcinoma, esophageal duplication cyst, metastatic disease, lymphadenopathy (all causes), hiatus hernia, bronchogenic cyst
• posterior (posterior to the middle line described above)
  ▪ neurogenic tumor (e.g. neurofibroma, schwannoma), multiple myeloma, pheochromocytoma, neurenteric cyst, thoracic duct cyst, lateral meningocele, Bochdalek hernia, extramedullary hematopoiesis
• superior boundaries (superiorly by thoracic inlet, inferiorly by plane of the sternal angle, anteriorly by manubrium, posteriorly by T1-T4, laterally by pleura)
• in addition, any compartment may give rise to lymphoma, lung cancer, aortic aneurysm or other vascular abnormalities, abscess, and hematoma

Enlarged Cardiac Silhouette
• heart borders
  ▪ on PA view, right heart border is formed by right atrium; left heart border is formed by left atrium and left ventricle
  ▪ on lateral view, anterior heart border is formed by right ventricle; posterior border is formed by left atrium (superior to left ventricle) and left ventricle
• cardiothoracic ratio = greatest transverse dimension of the central shadow relative to the greatest transverse dimension of the thoracic cavity
• using a good quality erect PA chest film in adults, cardiothoracic ratio of >0.5 is abnormal
• differential of ratio >0.5
  ▪ cardiomegaly (myocardial dilatation or hypertrophy)
  ▪ pericardial effusion
  ▪ poor inspiratory effort/low lung volumes
  ▪ pectus excavatum
• ratio <0.5 does not exclude enlargement (e.g. cardiomegaly + concomitant hyperinflation)
• pericardial effusion: globular heart with loss of indentations on left mediastinal border
• RA enlargement: increase in curvature of right heart border and enlargement of SVC
• LA enlargement: straightening of left heart border; increased opacity of lower right side of cardiovascular shadow (double heart border); elevation of left main bronchus (specifically, the upper lobe bronchus on the lateral film), distance between left main bronchus and “double” heart border >7 cm, splayed carina (late sign)
• RV enlargement: elevation of cardiac apex from diaphragm; anterior enlargement leading to loss of retrosternal air space on lateral; increased contact of right ventricle against sternum
• LV enlargement: displacement of cardiac apex inferiorly and posteriorly – “boot-shaped” heart
**Tubes, Lines, and Catheters**

- ensure appropriate placement and assess potential complications of lines and tubes
- avoid mistaking a line/tube for pathology (e.g. oxygen rebreather mask for pneumothoraces)

**Central Venous Catheter**
- used for fluid and medication administration, vascular access for hemodialysis, and CVP monitoring
- tip must be located proximal to right atrium to prevent inducing arrhythmias or perforating wall of atrium
  - if monitoring CVP, catheter tip must be proximal to venous valves
- tip of well positioned central venous catheter projects over silhouette of SVC in a zone demarcated superiorly by the anterior first rib and clavicle, and inferiorly by top of RA
- course should parallel course of SVC – if appears to bend as it approaches wall of SVC or appears perpendicular, catheter may damage and ultimately perforate wall of SVC
- complications: pneumothorax, bleeding (mediastinal, pleural), air embolism

**Endotracheal Tube**
- frontal chest film: tube projects over trachea and shallow oblique or lateral chest radiograph will help determine position in 3 dimensions
- progressive gaseous distention of stomach on repeat imaging is concerning for esophageal intubation
- tip should be located 4 cm above tracheal carina – avoids bronchus intubation and vocal cord irritation
- maximum inflation diameter <3 cm to avoid necrosis of tracheal mucosa and rupture – ensure diameter of balloon is less than tracheal diameter above and below balloon
- complications: aspiration (parenchymal opacities), pharyngeal perforation (subcutaneous emphysema, pneumomediastinum, mediastinitis)

**Nasogastric Tube**
- tip and sideport should be positioned distal to esophagogastric junction and proximal to gastric pylorus
- radiographic confirmation of tube is mandatory because clinical techniques for assessing tip position may be unreliable
- complications: aspiration (parenchymal opacities), intracranial perforation (trauma patients), pneumothorax

**Swan-Ganz Catheter**
- to monitor pulmonary capillary wedge pressure and to measure cardiac output for suspected LV dysfunction
- tip should be positioned within right or left main pulmonary arteries or in one of their large, lobar branches
- if tip is located more distally, increased risk of prolonged pulmonary artery occlusion resulting in pulmonary infarction or, rarely, pulmonary artery rupture
- complications: pneumothorax, bleeding (mediastinal, pleural), air embolism

**Chest Tube**
- in dorsal and caudal portion of pleural space to evacuate fluid
- in ventral and cephalad portions of pleural space to evacuate pneumothoraces
- tube may lie in fissure as long as functioning
- complications: lung perforation (mediastinal opacities)

**Abdominal Imaging**

**Abdominal X-Ray**

- indications
  - acute abdomen: bowel perforation, toxic megacolon, bowel ischemia, small bowel obstruction, large bowel obstruction
  - chronic symptoms: constipation, calcifications (gallstones, renal stones, urinary bladder stones, etc.)
  - not useful in: GI bleeds, chronic anemia, vague GI symptoms
- AXR 3 most common views: left lateral decubitus, supine, erect upright (see Figure 16, MI12)
Anatomy

- abdomen divided into 2 cavities
  - peritoneal cavity: lined by peritoneum that wraps around most of the bowel, the spleen, and most of the liver; forms a recess lateral to both the ascending and descending colon (paracolic gutters)
  - retroperitoneal cavity: contains several organs situated posterior to the peritoneal cavity; the contour of these can often be seen on radiographs

</tbody>
</table>

Approach to Abdominal X-Ray

- mnemonic: “Free ABDO”
- Free = free air and fluid
  - free fluid
    - small amounts of fluid: increased distance between lateral fat stripes and adjacent colon may indicate free peritoneal fluid in the paracolic gutters
    - large amounts of fluid: diffuse increased opacification on supine film; bowel floats to center of anterior abdominal wall
    - ascites and blood (hemoperitoneum) are the same density on the radiograph and therefore cannot be differentiated
    - free intraperitoneal air suggests rupture of a hollow viscus (anterior duodenum, transverse colon), penetrating trauma, or recent (<7 d) surgery
  - A = air in the bowel (can be normal, ileus, or obstruction)
    - volvulus – twisting of the bowel upon itself; from most to least common:
      - sigmoid: “coffee bean” sign (massively dilated sigmoid projects to right or mid-upper abdomen) with proximal dilation
      - cecal: massively dilated bowel loop projecting to left or mid-upper abdomen with small bowel dilation
      - gastric: rare
      - transverse colon: rare (usually young individuals)
      - small bowel: “corkscrew sign” (rarely diagnosed on plain films, seen best on CT)
      - toxic megacolon
    - manifestation of fulminant colitis
      - extreme dilatation of colon (>6.5 cm) with mucosal changes (e.g. foci of edema, ulceration, pseudopolyps), loss of normal haustral pattern
  - B = bowel wall thickening
    - increased soft tissue density in bowel wall, thumb-like indentations in bowel wall (“thumb-printing”), or a picket-fence appearance of the valvulae conniventes ("stacked coin" appearance)
    - may be seen in IBD, infection, ischemia, hypoproteinemic states, and submucosal hemorrhage
  - D = densities
    - bones: look for gross abnormalities of lower ribs, vertebral column, and bony pelvis
    - abnormal calcifications: approach by location
      - RUQ: renal stone, adrenal calcification, gallstone, porcelain gallbladder
      - RLQ: ureteral stone, appendicolith, gallstone ileus
      - LUQ: renal stone, adrenal calcification, tail of pancreas
      - LLQ: ureteral stone
      - central: aorta/aortic aneurysm, pancreas, lymph nodes
      - pelvis: phleboliths (i.e. calcified veins), uterine fibroids, bladder stones
  - O = organs
    - kidney, liver, gallbladder, spleen, pancreas, urinary bladder, psoas shadow
    - outlines can occasionally be identified because they are surrounded by more lucent fat, but all are best visualized with other imaging modalities (CT, MRI)

What’s in the Retroperitoneum?

- Duodenum (2nd, 3rd, 4th part)
- Ascending and descending colon
- Rectum
- Kidneys, ureters, bladder, adrenals
- Psoas, quadratus lumborum
- Aorta, inferior vena cava
- Pancreas

Approach to AXR

Free ABDO
- Free fluid or air (outside bowel)
- Air in the bowel
- Bowel wall thickening
- Densities (bones, calcifications)
- Organs

</tbody>
</table>

Abdominal CT
- indications for plain CT: renal colic, hemorrhage
- indications for CT with contrast
  - IV contrast given immediately before or during CT to allow identification of arteries and veins
    - portal venous phase: indicated for majority of cases
    - biphase (arterial and portal venous phases): liver, pancreas, bile duct tumors
  - oral contrast: barium or water soluble (water soluble if suspected perforation) given in most cases to demarcate GI tract
  - rectal contrast: given for investigation of colonic lesions
  - caution: contrast allergy (may premedicate with steroids and antihistamine)
  - contraindication: impaired renal function, based on eGFR

Biliary vs. Portal Venous Air
- “Go with the flow”: air follows the flow of bile or portal venous blood
- Biliary air is most prominent centrally over the liver
- Portal venous air is most prominent peripherally

ICV Function in Large Bowel Obstruction
- Competent ICV: Distention of large bowel between obstruction and ICV, small bowel unaffected
- Higher risk of perforation, especially with cecal distention >10 cm
- Incompetent ICV: Distention of large and small bowel
Approach to Abdominal Computed Tomography

- look through all images in gestalt fashion to identify any obvious abnormalities
- look at each organ/structure individually, from top to bottom evaluating size and shape of each area of increased or decreased density
- evaluate the following
  - soft tissue window
    - liver, gallbladder, spleen, and pancreas
    - adrenals, kidneys, ureters, and bladder
    - stomach, duodenum, small bowel mesentery, and colon/appendix
    - retroperitoneum: aorta, vena cava, and mesenteric vessels; look for adenopathy in vicinity of vessels
    - peritoneal cavity for fluid or masses
    - abdominal wall and adjacent soft tissue
  - lung window
    - visible lung (bases)
  - bone window
    - vertebrae, spinal cord, and bony pelvis

CT and Bowel Obstruction

- cause of bowel obstruction rarely found on plain films – CT is best choice for imaging
- the “3,6,9” rule is a very useful guide to determining when the bowel is dilated; the maximum diameter of the bowel is 3 cm for small bowel, 6 cm for large bowel, and 9 cm for cecum; this can also be useful to distinguish small and large bowel, and to assess for ‘impending’ cecal perforation (e.g. post-un-treated Ogilvie’s syndrome)
- closed-loop obstruction: an obstruction in two locations (usually small bowel) creating a loop of bowel segment obstructed both proximally and distally; complications (e.g. ischemia, perforation, necrosis) may occur quickly

CT Colonography (virtual colonoscopy)

- emerging imaging technique for evaluation of intraluminal colonic masses (i.e. polyps, tumors)
- two CT scans of the abdomen (prone and supine) after the instillation of carbon dioxide into a prepped colon
- computer reconstruction of 2D CT images into a 3D intraluminal view of the colon in order to look for masses
- lesions seen on 3D images correlated with 2D axial images
- indications: surveillance in low-risk patients, incomplete colonoscopy, staging of obstructing colonic lesions

Contrast Studies

Table 10. Types of Contrast Studies

</tbody>
</table>
Specific Visceral Organ Imaging

Liver
- U/S: assessment of cysts, abscesses, tumors, biliary tree
- CT ± IV: most popular procedure for imaging the liver parenchyma (primary liver tumors, metastases, cysts, abscesses, trauma, cirrhosis)
- MR: also excellent in evaluation of primary liver tumors, liver metastases, and other parenchymal conditions, and is particularly helpful in differentiating common benign hepatic hemangiommas from primary liver tumors and metastases
- findings
  - advanced cirrhosis: liver small and irregular (fibrous scarring, segmental atrophy, regenerating nodules)
  - portal HTN: increased portal vein diameter, collateral veins, splenomegaly (≥12 cm), portal vein thrombosis, recanalization of the umbilical vein
  - porto-systemic shunts: caput medusa, esophageal varices, spontaneous spleno-renal shunt
- U/S: cirrhosis appears nodular and hypechoic with irregular areas of atrophy of the right lobe and hypertrophy of the caudate or left lobes
- CT: fatty infiltration appears hypodense
- in order to be visualized, some masses require contrast

<table>
<thead>
<tr>
<th>Table 11. Triphasic/Quadriphasic Liver Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>Phase</td>
</tr>
</tbody>
</table>
| Non-Contrast CT | 0 | • For all initial investigations of liver lesions  
  • Post radiofrequency ablation of liver tumors  
  • Not usually indicated for surveillance imaging |
| Arterial Phase | 20-30 s | • Early and late arterial phase on multidetector CT  
  • Late arterial phase best for discriminating hypervascular HCC |
| Portal Venous Phase | 60-70 s | • Provides maximum enhancement of hepatic tissue  
  • Most tumors supplied by hepatic artery are relatively hypovascular, therefore appear as low-attenuation masses in portal venous phase  
  • Hypervascular tumors wash out (HCC) |
| Equilibrium (Delayed) Phase | 120-180 s | • Hemangioma: persistent enhancement suggests blood  
  • Enhancement of fibrous/scar tissue (HCC capsule, focal nodular hyperplasia, cholangiocarcinoma) |

<table>
<thead>
<tr>
<th>Table 12. Imaging of Liver Masses</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mass</td>
</tr>
</tbody>
</table>
| Metastases            | Multiple masses of variable echotexture  
  Usually low attenuation on contrast enhanced scan |
| HCC                   | Single/multiple masses, or diffuse infiltration  
  Hypervascular enhances in arterial and washes out in venous phase with portal venous tumor thrombus |
| Abscess               | Poorly defined, irregular margin, hypoechoic contents  
  Low-attenuation lesion with an irregular enhancing wall |
| Hydatid Cyst          | Simple/multiloculated cyst  
  Low-attenuation simple or multiloculated cyst; calcification |
| Hemangioma            | Homogeneous hypechoic mass  
  Peripheral globular enhancement in arterial phase scans; central-filling and persistent enhancement on delayed scans |
| Focal Nodular Hyperplasia | Well-defined mass, central scar seen in 50%  
  Hypervascular mass in arterial phase and isoattenuation to liver in portal venous phase |
| Hepatic Adenoma       | Most common in young women taking oral contraceptives. Well-defined mass with hypechoic areas due to hemorrhage  
  Well-defined hypervascular lesion with enlarged central vessel becoming slightly isoattenuating in venous phase |

Spleen
- U/S, CT, nuclear medicine scan (nuclear medicine only to distinguish ectopic splenic tissue from enhancing tumors)
- CT for splenic trauma (hemorrhage)

Biliary Tree
- U/S: bile ducts usually visualized only if dilated, secondary to obstruction (e.g. choledocholithiasis, benign stricture, mass)
- CT: dilated intrahepatic ductules seen as branching, tubular structures following pathway of portal venous system
- MRCP, ERCP, PTC: further evaluation of obstruction and possible intervention

Figure 18. ERCP: biliary tree

Liver Mass DDx
- 5 Hs
  - HCC
  - Hydatid cyst
  - Hemangioma
  - Hepatic adenoma
  - Hyperplasia (focal nodular)

Revised Estimates of Diagnostic Test Sensitivity and Specificity in Suspected Biliary Tract Disease
Arch Intern Med 1998;158:2573-2581

Purpose: To assess the sensitivity and specificity of tests used to diagnose cholelithiasis and acute cholecystitis, including ultrasonography, oral cholecystography, radionuclide scanning with Technetium, MRI, CT.

Study Characteristics: Meta-analysis of 30 studies evaluating the use of different imaging modalities in the diagnosis of biliary tract disease.

Participants: No limits.

Main Outcomes: Sensitivity and specificity of the different imaging modalities, using the gold standard of surgery, autopsy, or 3 mo clinical follow-up for cholecystitis. For acute cholecystitis, pathologic findings, confirmation of an alternate disease, or clinical resolution during hospitalization for cholecystitis were used as the standard.

Results: For evaluating cholecystitis, US had the best unadjusted sensitivity (0.97; 95% CI 0.95-0.99) and specificity (0.98; 95% CI 0.96-1.00) and adjusted (for verification bias) sensitivity (0.94; 95% CI 0.76-1.00) and specificity (0.98; 95% CI 0.97-1.00). For evaluating acute cholecystitis, radionuclide scanning has the best sensitivity (0.97; 95% CI 0.86-0.98) and specificity (0.98; 95% CI 0.89-0.97).

Conclusions: US is the test of choice for diagnosing cholecystitis and radionuclide scanning is the superior test for diagnosing acute cholecystitis.
Pancreas
- tumors
  - U/S: mass is more echogenic than normal pancreatic tissue
  - CT: preferred modality for diagnosis/staging
- ductal dilation secondary to stone/tumor
- ERCP: imaging of ductal system using MRI cholangiography; no therapeutic potential
- MRCP: imaging of ductal system using MRI; therapeutic potential (stent placement, stone retrieval); acute pancreatitis is a complication in 5% of diagnostic procedures and 10% of therapeutic procedures

“itis” Imaging

Acute Cholecystitis
- pathogenesis: inflammation of gallbladder resulting from sustained gallstone impaction in cystic duct or, in the case of acalculous cholecystitis, due to gallbladder ischemia or cholestasis (see General Surgery, GS46)
- best imaging modality: U/S (best sensitivity and specificity); nuclear medicine (HIDA scan) can help diagnose cases of acalculous or chronic cholecystitis
- findings: thick wall, pericholecystic fluid, gallbladder, positive sonographic Murphy's sign
- management: cholecystectomy

Acute Appendicitis
- pathogenesis: luminal obstruction → bacterial overgrowth → inflammation/swelling → increased pressure → localized ischemia → gangrene/perforation → localized abscess or peritonitis (see General Surgery, GS28)
- best imaging modality: U/S or CT
- findings
  - U/S: thick-walled appendix, appendicolith, dilated fluid-filled appendix, non-compressible; may also demonstrate other causes of RLQ pain (e.g. ovarian abscess, IBD, ectopic pregnancy)
  - CT: enlargement of appendix (>6 mm in outer diameter), enhancement of appendiceal wall, adjacent inflammatory stranding, appendicolith; also facilitates percutaneous abscess drainage
- management: appendectomy

Acute Diverticulitis
- pathogenesis: erosion of the intestinal wall (most commonly rectosigmoid) by increased intraluminal pressure or inspissated food particles → inflammation and focal necrosis → micro- or macroscopic perforation (see General Surgery, GS31)
- best imaging modality: CT is modality of choice, although U/S is sometimes used
- contrast: oral and rectal contrast given before CT to opacify bowel
- findings
  - cardinal signs: thickened wall, mesenteric infiltration, gas-filled diverticula, abscess
  - CT can be used for percutaneous abscess drainage before or in lieu of surgical intervention
  - sometimes difficult to distinguish from perforated cancer (therefore send abscess fluid for cytology and follow up with colonoscopy)
  - if chronic, may see fistula (most common to bladder) or sinus tract (linear or branching structures)
- management: ranges from antibiotic treatment to surgical intervention; can use imaging to follow progression

Acute Pancreatitis
- pathogenesis: activation of proteolytic enzymes within pancreatic cells leading to local and systemic inflammatory response (see Gastroenterology, G50); a clinical/biochemical diagnosis
- best imaging modality: imaging used to support diagnosis and evaluate for complications (diagnosis cannot be excluded by imaging alone)
  - U/S good for screening and follow-up
  - CT is useful in advanced stages and in assessing for complications (1st line imaging test)
- findings
  - U/S: hypoechoic enlarged pancreas (if ileus present, gas obscures pancreas)
  - CT: enlarged pancreas, edema, stranding changes in surrounding fat with indistinct fat planes, mesenteric and Gerota's fascia thickening, pseudocyst in lesser sac, abscess (gas or thick-walled fluid collection), pancreatic necrosis (low attenuation gas-containing non-enhancing pancreatic tissue), hemorrhage
- management: supportive therapy
  - CT-guided needle aspiration and/or drainage done for abscess when clinically indicated
  - pseudocyst may be followed by CT and drained if symptomatic

Computed Tomography and Ultrasonography to Detect Acute Appendicitis in Adults and Adolescents
Ann Intern Med 2004;141:537-546
Purpose: To review the diagnostic accuracy of CT or ultrasonography in the diagnosis of acute appendicitis.
Study Characteristics: Meta-analysis of 22 prospective studies evaluating the use of CT or ultrasonography, followed by surgical or clinical follow-up in patients with suspected appendicitis.
Participants: Age 14 and older with a clinical suspicion of appendicitis.
Main Outcomes: Sensitivity and specificity using surgery or clinical follow-up as the gold standard.
Results: CT (12 studies) had an overall sensitivity of 0.94 (95% CI 0.91-0.95) and a specificity of 0.95 (95% CI 0.93-0.96); Ultrasonography (14 studies) had an overall sensitivity of 0.81 (95% CI 0.79-0.83) and a specificity of 0.81 (95% CI 0.78-0.84).
Conclusions: CT is more accurate for diagnosing appendicitis in adults and adolescents, although verification bias and inappropriate blinding of reference standards were noted in the included studies.

Angiography requires active blood loss 1-1.5 mL/min under optimal conditions for a bleeding site to be visualized in cases of lower GI bleeding.
Chronic Pancreatitis
- pathogenesis: (see Gastroenterology, G51)
- best imaging modality: MRCP (can show calcification and duct obstruction)
- findings: U/S, CT scan, and MRI may show calcifications, ductal dilatation, enlargement of the pancreas and fluid collections (e.g. pseudocysts) adjacent to the gland

**Angiography of GI Tract**

- anatomy of the GI tract arterial blood supply branches
  - celiac artery: hepatic, splenic, gastroduodenal, left/right gastric
  - superior mesenteric artery: jejunal, ileal, ileo-colic, right colic, middle colic
  - inferior mesenteric artery: left colic, superior rectal
- imaging modalities
  - conventional angiogram: invasive (usual approach via femoral puncture), catheter used
    - flush aortography: catheter injection into abdominal aorta, followed by selective arteriography of individual vessels
  - CT angiogram: modality of choice, non-invasive using IV contrast (no catheterization required)

**Genitourinary System and Adrenal**

**Urological Imaging**

**KUB**
- a frontal supine radiograph of the abdomen
- indication: useful in evaluation of radio-opaque renal stones (all stones but uric acid and indinavir), as well as indwelling ureteric stents or catheters
- findings: addition of IV contrast excreted by the kidney (intravenous urogram) allows greater visualization of the urinary tract, but has been largely replaced by CT urography

**Abdominal CT**

**Renal Masses**
- Bozniak classification for cystic renal masses
  - class I-II: benign and can be disregarded
  - class III: should be followed
  - class III-IV: suspicious for malignancy, requiring additional workup

<table>

- plain CT KUB
  - indications: general imaging of renal anatomy, renal colic symptoms, assessment of renal calculi (size and location), and hydronephrosis prior to urological treatment
- CT urography
  - indications: investigation of cause of microscopic/gross hematuria, detailed assessment of urinary tracts (excretory phase), high sensitivity (95%) for uroepithelial malignancies of the upper urinary tracts, assessment of renal calculi
  - phases: unenhanced, excretory
- renal triphasic CT
  - indications: standard imaging for renal masses, allows accurate assessment of renal arteries and veins, better characterization of suspicious renal masses, especially in differentiating renal cell carcinoma from more benign masses, and pre-operative staging
  - phases: unenhanced, arterial and venous (nephrographic)
Ultrasound
• Indications: initial study for evaluation of kidney size and nature of renal masses (solid vs. cystic renal masses vs. complicated cysts); technique of choice for screening patients with suspected hydronephrosis (no IV contrast injection, no radiation to patient, and can be used in patients with renal failure); TRUS useful to evaluate prostate gland and guide biopsies; Doppler U/S to assess renal vasculature
• Findings: solid renal masses are echogenic (bright on U/S), cystic renal masses have smooth well-defined walls with anechoic interior (dark on U/S), and complicated cysts have internal echoes within a thickened, irregular wall

Retrograde Pyelography
• Indications: visualize the urinary collecting system via a cystoscope, ureteral catheterization, and retrograde injection of contrast medium, ordered when the intrarenal collecting system and ureters cannot be opacified using intravenous techniques (patient with impaired renal function, high grade obstruction)
• Findings: only yields information about the collecting systems (renal pelvis and associated structures), no information regarding the parenchyma of the kidney

Voiding Cystourethrogram
• Bladder filled with contrast to the point where voiding is triggered
• Fluoroscopy (continuous, real-time) to visualize bladder
• Indications: children with recurrent UTIs, hydronephrosis, hydroureter, suspected lower urinary tract obstruction or vesicoureteral reflux
• Findings: contractility and evidence of vesicoureteric reflux

Retrograde Urethrogram
• A small Foley catheter placed into penile urethral opening
• Indications: used mainly to study strictures or trauma to the male urethra; first-line study if trauma with blood present at urethral meatus

MRI
• Advantages: high spatial and tissue resolution, lack of exposure to ionizing radiation and nephrotoxic contrast agents
• Indications: indicated over CT for depiction of renal masses in patients with previous nephron sparing surgery, patients requiring serial follow-up (less radiation dosage), patients with reduced renal function, and patients with solitary kidneys

Renal Nuclear Scan

Gynecological Imaging

Ultrasound
• Transabdominal and transvaginal are the primary modalities, and are indicated for different scenarios
• Transabdominal requires a full bladder to push out air containing loops of bowel
  ▪ Indication: good initial investigation for suspected pelvic pathology
  ▪ TVUS provides enhanced detail of deeper/smaller structures by allowing use of higher frequency sound waves at reduced distances
  ▪ Indication: improved assessment of ovaries, first trimester development, and ectopic pregnancies

Hysterosalpingogram
• Indications: useful for assessing pathology of the uterine cavity and fallopian tubes, evaluating uterine abnormalities (e.g. bicornuate uterus), or evaluation of fertility (absence of flow from tubes to peritoneal cavity indicates obstruction)
• Performed by x-ray images of the pelvis after cannulation of the cervix and subsequent injection of opacifying agent

CT/MRI
• Indications: evaluating pelvic structures, especially those adjacent to the adnexa and uterus
• Invaluable for staging gynecological malignancies

Pregnancy should always be ruled out by β-hCG before CT of a female pelvis (or any organ system) is performed
Sonohysterogram
- saline infusion sonohysterogram involves instilling fluid into the uterine cavity transcervically to provide enhanced endometrial visualization during transvaginal U/S examination
- indications: abnormal uterine bleeding, uterine cavity abnormalities that are suspected or noted on transvaginal U/S (e.g. leiomyomas, polyps, synechiae), congenital abnormalities of the uterine cavity, infertility, recurrent pregnancy loss
- contraindications: pregnancy, pelvic infection

Adrenal Mass
- imaging modality: most often identified on CT scan as ‘incidentaloma’, can also use CT/MRI to distinguish benign from malignant masses

Neuroradiology

Modalities
- CT is the modality of choice for most neuropathology; even under circumstances when MRI is preferred, CT is frequently the initial study because of its speed, availability, and lower cost
  - acute head trauma: CT is best for visualizing “bone and blood”; MRI is used only when CT fails to detect an abnormality despite strong clinical suspicion
  - acute stroke: MRI ideal, CT most frequently used
  - suspected subarachnoid or intracranial hemorrhage
  - meningitis: rule out mass effect (e.g. cerebral herniation, shift) prior to lumbar puncture
  - tinnitus and vertigo: CT and MRI are used in combination to detect bony abnormalities and CN VIII tumors, respectively

Figure 26. Epidural hematoma
Skull Films
- rarely performed, generally not indicated for non-penetrating head trauma
- indications: screening for destructive bony lesions (e.g. metastases), metabolic disease, skull anomalies, post-operative changes and confirmation of hardware placement, skeletal surveys

CT
- excellent study for evaluation of bony abnormalities
- often done first without and then with IV contrast to show vascular structures or anomalies
- vascular structures and areas of blood-brain barrier impairment are opaque (e.g. hyperattenuating or white/show enhancement) with contrast injection
  ▪ when in doubt, look for circle of Willis or confluence of sinuses to determine presence of contrast enhancement
- posterior fossa can be obscured by extensive bony artifact
- rule out skull fracture, epidural hematoma (lenticular shape), subdural hematoma (crescentic shape), subarachnoid hemorrhage, space occupying lesion, hydrocephalus, and cerebral edema
- multiplanar imaging can be performed with newer generation of multidetector CT scanners

Myelography
- introduction of water-soluble, low-osmotic contrast media into subarachnoid space using lumbar puncture followed by x-ray or CT scan
- indications: excellent study for disc herniations, traumatic nerve root avulsions, patients with contraindication to MRI

MRI
- indications: shows brain and spinal soft tissue anatomy in fine detail, clearly distinguishes white from gray matter (especially T1-weighted series), multiplanar reconstruction helpful in pre-operative assessment

Cerebral Angiography/CTA/MRA
- indications: evaluation of vascular lesions such as atherosclerotic disease, aneurysms, vascular malformations, arterial dissection
- conventional DSA remains the gold standard for the assessment of neck and intracranial vessels; however, it is an invasive procedure requiring arterial (femoral) puncture; catheter manipulation has risk of vessel injury (e.g. dissection, occlusion, vasospasm, emboli)
- MRA methods (phase contrast, time of flight, gadolinium-enhanced) and CTA are much less invasive without actual risk to intracranial or neck vessels
- MRA and CTA are often used first as ‘screening tests’ for the assessment of subarachnoid hemorrhage, vasospasm, aneurysms

Nuclear Medicine
- SPECT using $^{99m}$Tc-exametazime (HMPAO) and $^{99m}$Tc-bicisate (ECD) imaging assesses cerebral blood flow by diffusing rapidly across the blood brain barrier and becoming trapped within cells
- $^{18}$FDG PET imaging assesses cerebral metabolic activity

<tr>
<th>Type</th>
<th>Cause</th>
</tr>
</thead>
<tbody>
<tr>
<td>Communicating/Extra-Ventricular</td>
<td>Obstruction distal to the ventricles (e.g. at the level of the arachnoid granulations); imaging shows all ventricles dilated</td>
</tr>
<tr>
<td>Non-Communicating</td>
<td>Obstruction within the ventricular system (e.g. mass obstructing the aqueduct or foramen of Monro); imaging shows dilatation of ventricles proximal to the obstruction</td>
</tr>
</tbody>
</table>
Approach to CT Head

- think anatomically, work from superficial to deep
- scan: confirm that the imaging is of the correct patient, whether contrast was used, if the patient is aligned properly, if there is artifact present
- skin/soft tissue: examine the soft tissue superficial to the skull, looking for thickening suggestive of hematoma or edema; also investigate ear, orbital contents (globe, fat, muscles), parotid, muscles of mastication (masseter, temporalis, pterygoids), visualized pharynx
- bone and airspace (use the bone window): check calvarium, visualize mandible, visualize C-spine (usually C1 and maybe part of C2) for fractures, absent bone, lytic/sclerotic lesions; inspect sinuses and mastoid air cells for opacity that may suggest fluid, pus, blood, tumor, or fracture; status of the orbital floor in cases of facial trauma (coronal series best)
- dura and subdural space: crescent-shaped hyperdensity in the subdural space suggests subdural hematoma; lentiform hyperdensity in the epidural space suggests epidural hematoma; check symmetry of dural thickness, where increased thickness may suggest the presence of blood
- parenchyma: asymmetry of the parenchyma suggests midline shift; poor contrast between gray and white matter suggests possible infarction, tumor, edema, infection, or contusion; hyperdensity in the parenchyma suggests enhancing lesions, intracerebral hemorrhage, or calcification; central gray matter nuclei (e.g. globus pallidus, putamen, internal capsule) should be visible, otherwise, suspect infarct, tumor, or infection
- ventricles/sulci/cisterns: examine position of ventricles for evidence of midline compression/shift; hyperdensities in the ventricles suggest ventricular/subdural hemorrhage; enlarged ventricles suggest hydrocephalus; obliteration of sulci may suggest presence of edema causing effacement, possible blood filling in the sulci, or tumor; cistern hyperdensities may suggest blood, pus, or tumor

Selected Pathology

- see Neurosurgery, NS4-22 for intracranial mass lesions
- see Neurosurgery, NS29 and Plastic Surgery, PL28 for head trauma
- see Emergency Medicine, ER9 for vertebral trauma
- see Neurosurgery, NS23-27 and Orthopedics, OR21 for degenerative spinal abnormalities

Cerebrovascular Disease (see Neurology, N43 and Neurosurgery, NS17)

- pathogenesis of stroke: see Neurology, N47
- best imaging modality: infarcts best detected by either CT or MRI
- findings of infarction
  - early changes
    - CT
      - usually normal within 6 h of infarction
      - edema (loss of gray-white matter differentiation – “insular ribbon” sign, effacement of sulci, mass effect)
      - within 24 h, loss of low-density, wedge-shaped area of infarction extending to periphery (correlating to vascular territory distal to affected artery)
      - in case of ischemic stroke, may see hyperattenuating (bright) artery (hyperdense MCA sign) representing intravascular thrombus or embolus
      - in case of hemorrhagic stroke or transformation (common in basal ganglia and cortex), may see bright acute blood surrounded by edema
    - MRI
      - edema with high signal on T2-weighted images and FLAIR image (loss of gray-white matter differentiation, effacement of sulci, mass effect)
      - DWI shows acute high signal changes demonstrating restricted movement of water indicative of cytotoxic edema; usually indicates stroke damage before CT
      - apparent diffusion coefficient image shows low signal intensity in acute ischemia (nadir 3-5 d, returns to baseline 1-4 wk)
  - subacute changes on CT and MRI
    - edema and mass effect more prominent
    - gyral enhancement with contrast indicative of blood-brain barrier breakdown
  - chronic changes on CT and MRI
    - encephalomalacia (parenchymal volume loss) with dilatation of adjacent ventricles
- carotid artery disease
  - best imaging modality: Duplex Doppler U/S
  - other modalities: MRA or CTA if carotid angioplasty or endarterectomy is under consideration (conventional angiography reserved for inadequate MRA or CTA)
Multiple Sclerosis (refer to Neurology, N52)
- best imaging modality: MRI has high sensitivity in diagnosing MS (>90%) but low specificity (71-74%)
- findings
  - characteristic lesion on MRI is cerebral or spinal plaque
  - plaques typically found in periventricular region, corpus callosum (arranged at right angles to the corpus callosum), centrum semiovale, and to a lesser extent in deep white matter structures and basal ganglia
  - "Dawson’s fingers" refers to perivenular regions of demyelination that are seen to radiate outwards into the deep periventricular region
  - plaques usually have ovoid appearance, hyperintense on T2 and hypointense on T1
  - conventional T2 may underestimate plaque size and overall plaque burden – advanced techniques (diffusion tensor imaging and MR spectroscopy) can be of use
  - perivascular and interstitial edema may be prominent
  - spinal cord lesions typical of MS
    - little or no cord swelling
    - unequivocal hyperintensity on T2-weighted sequences
    - size at least 3 mm but less than 2 vertebral segments in length
    - occupy only part of the cord in cross-section
    - focal (i.e. clearly delineated and circumscribed on T2-weighted sequences)

CNS Infections
- leptomeningitis
  - pathogenesis: inflammation of the pia or arachnoid mater, most often secondary to hematogenous spread from infection or via organisms gaining access across areas not protected by the blood-brain barrier (choroid plexus or circumventricular organs)
  - pathogens include: S. pneumoniae, H. influenzae, N. meningitidis, L. monocytogenes
  - best imaging modality: MRI (T2-weighted/FLAIR) superior to CT
  - findings
    - meningeal enhancement (following the gyri/sulci, and/or basal cisterns), hydrocephalus (communicating), cerebral swelling, subdural effusion
    - a normal MRI does not rule out leptomeningitis

- herpes simplex encephalitis (see Infectious Diseases, ID20)
  - pathogenesis: inflammation of the brain parenchyma secondary to infection with herpes simplex virus, asymmetrically affects the limbic regions of the brain (i.e. temporal lobes, orbitofrontal region, insula, and cingulate gyrus)
  - best imaging modality: MRI (T1- and T2-weighted)
  - findings
    - acute (within 4-5 d): asymmetric high intensity lesions on T2 MRI in temporal and inferior frontal lobes strongly suggestive
    - DDx: infarct, tumor, status epilepticus, limbic encephalitis
    - CT may show low density in temporal lobe and insula; rarely basal ganglia involvement
    - long-term may show parenchymal loss to affected areas

- cerebritis/cerebral abscess
  - pathogenesis: an infection of the brain parenchyma (cerebritis) which can progress to a collection of pus (abscess), most frequently due to hematogenous spread of infectious organisms, commonly located in the distribution of the MCA
  - pathogens include: S. aureus (often in IV drug users, nosocomial), Streptococcus, Gram negative bacteria, Bacteroides
  - best imaging modality: MRI including DWI imaging series (abscess will be DWI positive); CT still used as a viable alternative
  - findings according to one of four stages of abscess formation:
    - early cerebritis (1-3 d): inflammatory infiltrate with necrotic center, low intensity on T1, high intensity on T2
    - late cerebritis (4-9 d): ring enhancement may be present
    - early capsule (10-13 d): ring enhancement
    - late capsule (14 d or greater): well demarcated ring-enhancing lesion, low intensity core, with mass effect; considerable edema around the lesion, seen as hyperintensity on T2
Musculoskeletal System

Modalities

Plain Film/X-Ray
- usually initial study used in evaluation of bone and joint disorders
- indications: fractures and dislocations, arthritis, assessment of malalignment, orthopedic hardware, and bone tumors (initial)
- minimum of two films orthogonal to each other (usually AP and lateral) to rule out a fracture
- image proximal and distal joints (particularly important with paired bones (e.g. radius/ulna)
- minimally effective in evaluating soft tissue injury
- advantages: fast, inexpensive, readily available, reproducible

CT
- evaluation of fine bony detail
- indications: assessment of complex, comminuted, intra-articular or occult fractures including distal radius, scaphoid, skull, spine, acetabulum, calcaneus, and sacrum
- evaluation of soft tissue calcification/ossification
- advantages: fast, reproducible, excellent bone evaluation, and spatial resolution
- disadvantages: radiation dose, relatively poor soft tissue characterization in comparison with U/S and MRI

MRI
- indications: evaluation of internal derangement of joints (e.g. ligaments, joint capsule, menisci, labrum, cartilage), assessment of tendons and muscle injuries, characterization and staging of soft tissue and bony masses
- advantages: excellent soft tissue contrast, multiplanar imaging, no radiation
- disadvantages: long imaging times, expensive, claustrophobia, contraindications (e.g. pacemakers, orbital metallic bodies), artifact around metal hardware

U/S
- indications: tendon injury (e.g. rotator cuff, Achilles tendon), detection of soft tissue masses and to determine whether cystic or solid, detection of foreign bodies, U/S guided biopsy and injections
- Doppler determines vascularity of structures
- advantages: good soft tissue evaluation, easy contralateral comparison, dynamic imaging
- disadvantages: operator dependent, poor for bone evaluation

Nuclear Medicine (Bone Scintigraphy)
- determine the location and extent of bony lesions
- 99mTc-methylene diphosphonate localizes to areas of increased bone turnover or calcification – growth plate in children, tumors, infections, fractures, metabolic bone disease (e.g. Paget's), sites of reactive bone formation, and periostitis
- advantages: very sensitive, capable of imaging entire body with relatively low dose radiation
- disadvantages: low specificity, not widely available due to special requirements (e.g. gamma camera, radiopharmaceuticals)

Approach to Interpretation of Bone X-Rays
- identification: name, MRN, age of patient, type of study, region of investigation
- soft tissues: swelling, calcification/ossification
- joints: alignment, joint space, presence of effusion, osteophytes, erosions, bone density, overall pattern, and symmetry of affected joint
- bone: periosteum, cortex, medulla, trabeculae, density, articular surfaces, bone destruction, bone production, appearance of the edges or borders of any lesions

Trauma

Fracture/Dislocation
- description of fractures
- site of fracture (bone, region of bone, intra-articular vs. extra-articular)
- pattern of fracture line (simple vs. comminuted)
- displacement (distal fragment with reference to the proximal fragment)
- soft tissue involvement (calcification, gas, foreign bodies)
- type of fracture (stress vs. pathologic)
- for specific fracture descriptions and characteristics of fractures, see Orthopedics, OR5

### Arthritis

Radiographic Hallmarks of Osteoarthritis
- joint space narrowing – typically non-uniform
- subchondral sclerosis
- subchondral cyst formation
- osteophytes

Radiographic Hallmarks of Rheumatoid Arthritis
- joint space narrowing – typically uniform
- soft tissue swelling
- erosions
- periarticular osteopenia

### Bone Tumor

**Approach**
- metastatic tumors to bone are much more common than primary bone tumors, particularly if age >40 yr
  - diagnosis usually requires a biopsy if primary not located
  - few benign tumors/lesions have potential for malignant transformation
  - MRI is good for tissue delineation and pre-operative assessment of surrounding soft tissues, neurovascular structures, and medullary/marrow involvement
  - plain film is less sensitive than other modalities but useful for assessing aggressiveness and constructing differential diagnosis

**Considerations and Tumor Characteristics**
- for specific bone tumors, see Orthopedics, OR43
- age – most common tumors by age group
  - <1 yr of age: metastatic neuroblastoma
  - 1-20 yr of age: Ewing’s sarcoma in tubular bones
  - 10-30 yr of age: osteosarcoma and Ewing’s sarcoma in flat bones
  - >40 yr of age: metastases, multiple myeloma, and chondrosarcoma
- multiplicity: metastases, myeloma, lymphoma, fibrous dysplasia, enchondromatosis
- location within bone
  - epihysis: giant cell tumor, chondroblastoma, geode, eosinophilic granuloma, infection
  - metaphysis: simple bone cyst, aneurysmal bone cyst, enchondroma, chordromyxoid fibroma, nonossifying fibroma, osteosarcoma, chondrosarcoma
  - diaphysis: fibrous dysplasia, aneurysmal bone cyst, brown tumors, eosinophilic granuloma, Ewing’s sarcoma
- expansile
  - aneurysmal bone cyst, giant cell tumor, enchondromas, brown tumors, metastases (especially renal and thyroid), plasmacytoma
- matrix mineralization
  - chondroid (popcorn calcification) or osseous
- margin/zono of transition: area between lesion and normal bone
  - cortex: intact, disturbed
  - periosteal reaction
  - soft tissue mass

### Margination of lesions

- Punched out
- Thin rim of sclerosis
- Thick rim of sclerosis

### Patterns of cortical disturbance

- Expand
- Endosteal scalloping
- Invisible margin

### Patterns of medullary destruction

- Permeative
- Moth-eaten
- Saucerization

### Periosteal new bone formation

- Onion-skin layered
- Codman’s Triangle
- Hair-on-end spiculated
- Sunburst divergent
- Solid undulating

---

Figure 37. X-ray of first carpometacarpal joint: normal image (left) and osteoarthritis (right) with joint space narrowing and subchondral sclerosis

Figure 38. Rheumatoid arthritis (A) compared with osteoarthritis (B) changes on X-ray

Benign Lesions which may have Aggressive Features
- Osteomyelitis
- Osteoblastoma
- Aneurysmal bone cyst
- Langerhans cell histiocytosis
- Myositis ossificans

Periosteal Reaction
- “Onion skinning” = Ewing’s sarcoma
- “Sunburst”, “hair on end” = osteosarcoma
- “Codman’s triangle” = osteosarcoma, Ewing’s sarcoma, subperiosteal abscess

Figure 39. Radiographic appearance of bone remodelling and destruction processes

</tbody>
</table>

**Metastatic Bone Tumors**
- all malignancies have potential to metastasize to bone
- metastases are 20-30x more common than primary bone tumors
- metastasis can cause a lytic or a sclerotic reaction when seeding to bone
- when a primary malignancy is first detected, a bone scan is often part of the initial workup
- may present with pathological fractures or pain
- biopsy or determination of primary is the only way to confirm the diagnosis
- most common metastatic bone tumors: breast, prostate, lung, see Orthopedics, OR46

**Infection**

**Osteomyelitis**
- MRI is the imaging modality of choice for demonstrating bone, bone marrow, and soft tissue abnormalities
- \( ^{99m} \text{Tc} \), followed by \( ^{111} \text{In} \) labeled white cell scan or gallium radioisotope scan
- plain film
  - visible 8-10 d after process has begun
  - osteomyelitic changes on plain film
    - soft tissue swelling
    - local periosteal reaction
    - pockets of air (from anaerobes) may be seen in the tissues, may also suggest necrotizing fascitis
    - mottled and nonhomogeneous with a classic “moth-eaten” appearance
    - cortical destruction

**Bone Abscess**
- overlying cortex has periosteal new bone formation
- sharply outlined radiolucent area with variable thickness in zone of transition
- variable thickness periosteal sclerosis
- sequestrum: a piece of dead bone within a Brodie’s abscess
- a sinus tract or cloaca may communicate between the abscess through the cortex to the surface of the bone
- best modality: MRI for bone, bone marrow, and soft tissue abnormalities; CT for sequestra and cortical erosions

**Metabolic Bone Disease**

**Osteoporosis**
- reduction in amount of normal bone mass; fewer and thinner trabeculae; diffuse process affecting all bones
- DEXA: gold standard for measuring bone mineral density
  - T-score: the number of standard deviations from the young adult mean, most clinically valuable
    - osteopenia: \(-2.5 < \text{T-score} < -1\)
    - osteoporosis: \(\text{T-score} \leq -2.5\)
  - Z-score: the number of standard deviations from the age-matched mean
  - risk of fracture: related to bone mineral density, age, history of previous fractures, steroid therapy
• appearance on plain film
  ▪ osteopenia: reduced bone density on plain films
  ▪ may also be seen with osteomalacia, hyperparathyroidism, and disuse
  ▪ compression of vertebral bodies
  ▪ biconcave vertebral bodies (“codfish” vertebrae)
  ▪ long bones have appearance of thinned cortex and increased medullary cavity
  ▪ look for complications of osteoporosis (e.g. insufficiency fractures: hip, vertebrae, sacrum, pubic rami)
• see Endocrinology, E42

Osteomalacia/Rickets
• reduction in bone mineral density, usually due to vitamin D deficiency, resulting in softening and bowing of long bones
• similar to osteoporosis, initial radiological appearance of osteopenia (coarse and poorly defined bone texture)
• “fuzzy”, ill-defined trabeculae
• Looser’s zones (pseudofracture)
  ▪ characteristic radiologic feature
  ▪ fissures or clefts at right angles to long bones and extending through cortex
• DDx: chronic renal disease, fibrous dysplasia, hyperthyroidism, Paget’s, osteodystrophy, X-linked hypophosphatemia

Hyperparathyroidism
• most common cause is renal failure (secondary hyperparathyroidism)
• chondrocalcinosis
  ▪ calcium crystal deposition in hyaline cartilage or fibrocartilage (including arteries and periarticular soft tissue)
  ▪ resorption of bone typically in hands (subperiosteal and at tufts), sacroiliac joints (subchondral), skull (“salt and pepper” appearance), osteoclastoma (brown tumors)
  ▪ “rugger jersey spine”: band-like osteosclerosis at superior/inferior margins of vertebral bodies
• see Endocrinology, E45

Paget’s Disease
• abnormal remodeling involving single or multiple bones – especially skull, spine, pelvis
• 3 phases: 1st phase = lytic, 2nd phase = mixed (lytic/sclerotic), 3rd phase = sclerotic
• features
  ▪ coarsening of the trabeculae with bone expansion
  ▪ bone softening/bowing
  ▪ bone scan will reveal high activity, especially at bone ends
  ▪ thickened cortex
• see Endocrinology, E46
Nuclear Medicine

Brain

• $^{99m}$Tc-HMPAO and $^{99m}$Tc-ECD imaging to assess cerebral blood flow, taken up in cortical and subcortical gray matter; used for dementia, traumatic brain injury and to a lesser extent vasculitis, neuropsychiatric disorders and stroke
• PET imaging assesses metabolic activity by using $^{18}$FDG
• CSF imaging, intrathecal administration of $^{111}$In DTPA to evaluate CSF leak or to differentiate normal pressure hydrocephalus from other causes of hydrocephalus
• ventricular shunt evaluation for obstruction (most commonly ventriculoperitoneal) with $^{99m}$Tc or $^{111}$In-DTPA

Thyroid

Radioactive Iodine Uptake (see Endocrinology, E21)
• index of thyroid function (trapping and organification of iodine)
• radioactive $^{131}$I or $^{123}$I given PO to fasting patient
• measure percentage of administered iodine taken up by thyroid
• increased RAIU: toxic multinodular goitre, toxic adenoma, Graves’ disease
• decreased RAIU: subacute thyroiditis, late Hashimoto’s disease, hormone suppression
• falsely decreased in patient with recent radiographic contrast studies, high dietary iodine (e.g. seaweed)

Thyroid Imaging (Scintiscan)
• $^{99m}$Tc/pertechnetate IV or radioactive iodine ($^{123}$I)
• provides functional anatomic detail
• hot (hyperfunctioning) lesions: usually benign (e.g. adenoma, toxic multinodular goitre), cancer very unlikely (less than 1%)
• cold (hypofunctioning) lesions: cancer must be considered until biopsy negative even though only 6-10% are cancerous
• isointense lesions: cancer must be considered as an isointense lesion may represent cold nodules superimposed on normal tissue; if cyst suspected, correlate with U/S
• serum thyroglobulin to detect recurrent thyroid cancer post-treatment

Radioiodine Ablation
• $^{123}$I for Graves’ disease, multinodular goitre, thyroid cancer

Respiratory

V/Q Scan
• examine areas of lung in which ventilation and perfusion do not match
• ventilation scan
  • patient breathes radioactive gas ($^{99m}$Tc-DTPA, $^{133}$Xe, Technegas) through a closed system, filling alveoli proportionally to ventilation
  • ventilation scan defects indicate: airway obstruction, chronic lung disease, bronchospasm, tumor mass obstruction
• perfusion scan
  • radiotracer injected IV ($^{99m}$Tc-MAA) → trapped in pulmonary capillaries (1 in 1500 arterioles occluded) according to blood flow
  • gives a map of pulmonary circulation
  • relatively contraindicated in severe pulmonary HTN and right-to-left shunt
• with PE
  • areas of lung are well ventilated but not perfused (unmatched defect)
  • defects are wedge-shaped, extend to periphery, usually bilateral and multiple
  • reported as high probability, intermediate, low, very low, or normal
• V/Q scans for PE have been largely replaced by CT scan with contrast (see Radiology, R19)
• not valid for assessment of PE when patients have intrinsic lung diseases and ventilatory problems
• modified V/Q scan (perfusion only, lower dose contrast) may be used for pregnant patients if CXR is normal

For PE investigation: normal scan makes PE unlikely
Probability of PE: high 80-100%, intermediate 20-80%, low <20%, very low <10%

Ventilation Scan Defects indicate:
Airway obstruction, chronic lung disease, bronchospasm, tumor mass obstruction

Perfusion Scan Defects indicate:
Reduced blood flow due to PE, COPD, asthma, bronchogenic carcinoma, inflammatory lung diseases (pneumonia, sarcoidosis), mediastinitis, mucous plug, vasculitis
Cardiac

Myocardial Perfusion Scanning
- for investigation of angina, atypical chest pain, CAD, and follow-up post-bypass
- thallium-201 (a radioactive analogue of potassium), $^{99m}$Tc-sestamibi, or $^{99m}$Tc-tetrofosmin
- injected at peak exercise (physical stress) or after persantine challenge (vasodilator) and again later at rest
- persistent defect (at rest and stress) suggests infarction; reversible defect (only during stress) suggests ischemia
- used to discriminate between reversible (ischemia) vs. irreversible (infarction) changes when other investigations are equivocal
- see Cardiology and Cardiac Surgery C13

Radionuclide Ventrilography
- $^{99m}$Tc tagged to red blood cells
- first pass through RV $\rightarrow$ pulmonary circulation $\rightarrow$ LV; provides information about RV function
- cardiac MUGA scan sums multiple cardiac cycles
- evaluation of LV function
- images are obtained by gating (synchronizing) the count acquisitions to the ECG signal
- MUGA scan can be used to study the function of the heart at a particular stage of contraction
- provides information on ejection fraction (normal = 50-65%), ventricular volume, and wall motion

Abdomen and Genitourinary System

HIDA Scan
- IV injection of $^{99m}$Tc-disofenin (DISIDA) or $^{99m}$Tc-mebrofenin which is bound to protein, taken up, and excreted by hepatocytes into biliary system
- can be performed in non-fasting state but prefer NPO after midnight
- gallbladder visualized when cystic duct is patent (rules out cholecystitis with >99% certainty), usually seen by 30 min to 1 h
- acute cholecystitis: no visualization of gallbladder at 4 h or after administration of morphine at 30 min
- chronic cholecystitis: no visualization of gallbladder at 1 h but seen at 4 h or after morphine administration
- differential diagnosis of obstructed cystic duct: acute/chronic cholecystitis, decreased hepatobiliary function (commonly due to alcoholism), bile duct obstruction, parenteral nutrition, fasting less than 4 h or more than 24 h
- assess bile leaks post-operatively

RBC Scan
- IV injection of radiotracer with sequential images of the abdomen ($^{99m}$Tc RBCs)
- GI bleed
  - if bleeding acutely at <0.5 mL/min, the focus of activity in the images generally indicates the site of the acute bleed, look for a change in shape and location on sequential image
  - if bleeding acutely at >0.5 mL/min, use angiography (more specific)
- liver lesion evaluation
  - hemangioma has characteristic appearance: cold early, fills in later

Bone

Bone Scan
- isotopes
  - $^{99m}$Tc-diphosphonate
    - triphasic bone scan: flow $\rightarrow$ blood pool $\rightarrow$ delayed bone images
    - uptake can distinguish bone vs. soft tissue infection and septic arthritis vs. osteomyelitis vs. peripheral cellulitis
    - acute osteomyelitis: increased activity in flow, blood pool, and delayed bone images; usually does not cross joint
    - septic arthritis and cellulitis: increased activity in blood pool and normal or slightly increased activity in delayed images; may cross joint
  - $^{111}$In WBC: tracks the active migration of the WBC, more specific for infection
  - $^{67}$Ga citrate: may see uptake in some tumors, also more specific for infection
- radioactive tracer binds to hydroxyapatite of bone matrix
• increased binding when increased blood supply to bone and/or high bone turnover (active osteoblasts)
• indications: bone pain of unknown origin, avascular necrosis, suspected malignancy, staging malignancy (breast, prostate, kidney or lung), follow up after treatment, detection and follow up of primary bone disease, assessment of skeletal trauma, detection of soft tissue calcification renal failure
• differential diagnosis of positive bone scan: bone metastases (breast, prostate, lung, thyroid), primary bone tumor, arthritis, fracture, infection, anemia, Paget's disease
• multiple myeloma: typically normal or cold (false negative); need a skeletal survey
• "superscan": increased bone uptake and poor renal uptake due to diffuse metastases or metabolic causes (renal osteodystrophy)

**Interventional Radiology**

**Vascular Procedures**

**Angiography**
• injection of contrast material through a catheter placed directly into an artery or vein to delineate vascular anatomy
• catheter can be placed into a large vessel (e.g. aorta, vena cava) for a “flush” or selectively placed into a branch vessel for more detailed examination of smaller vessels and specific organs
• indications: diagnosis of primary occlusive or stenotic vascular disease, aneurysms, coronary, carotid and cerebral vascular disease, PE, trauma, bleeding (GI, hemoptysis, hematuria), vascular malformations, as part of endovascular procedures (endovascular aneurysm repair, thrombolysis, stenting, and angioplasties)
• complications (<5% of patients): puncture site hematoma, infection, pseudoaneurysm, AV fistula, dissection, thrombosis, embolic occlusion of a distal vessel
due to improved technology, non-invasive evaluation of vascular structures is being performed more frequently (color Doppler U/S, CTA, and MRA)
• see **Neuroradiology, MI18**

**Percutaneous Transluminal Angioplasty and Stents**
• introduction and inflation of a balloon into a stenosed vessel to restore distal blood supply
• common alternative to surgical bypass grafting with 5 yr patency rates similar to surgery, depending on site
• renal, iliac, femoral, mesenteric, subclavian, coronary, and carotid artery stenoses are amenable to treatment
• vascular stents may help improve long-term results by keeping the vessel wall patent after PTA
• stents are also used for angioplasty failure or complications
• stent grafts (metal mesh covered with durable fabric) may provide an alternative treatment option for aneurysms and AV fistulas
• complications: similar to angiography, but also includes vessel rupture

**Thrombolytic Therapy**
• may be systemic (IV) or catheter directed
• infusion of a fibrinolytic agent (urokinase, streptokinase, TNK, tPA – used most commonly) via a catheter inserted directly into a thrombus
can restore blood flow in a vessel obstructed with a thrombus or embolus
• indications: treatment of ischemic limb (most common indication), early treatment of MI or stroke to reduce organ damage, treatment of venous thrombosis (DVT or PE)
• complications: bleeding, stroke, distal embolus, reperfusion injury with myoglobinuria and renal failure if advanced ischemia present

**Embolization**
• injection of occluding material into vessels
• permanent agents: amplatz plugs, coils, glue, and onyx
• temporary: gel foam, autologous blood clots
• indications: management of hemorrhage (epistaxis, trauma, GI bleed, GU bleed), treatment of arteriovenous malformation, pre-operative treatment of vascular tumors (bone metastases, renal cell carcinoma), varicocele embolization for infertility, symptomatic uterine fibroids
• complications: post-embolization syndrome (pain, fever, leukocytosis), unintentional embolization of a non-target organ with resultant ischemia

---

Cochrane DB Syst Rev 2009;3:CD004437

**Study:** Systematic review of RCTs comparing thrombolytic therapy with placebo, heparin, or surgical intervention.

**Patients:** 679 patients with acute PE.

**Intervention:** Thrombolytics vs. heparin or placebo.

**Outcome:** Death rate, recurrence of PE, major and minor hemorrhagic events.

**Results:** Non-significant difference between thrombolytics and heparin or placebo in all measured outcomes. Rt-PA and heparin together reduced need for treatment for in-hospital events. Thrombolytics improved hemodynamic outcome, lung VQ scans, pulmonary angiography assessment, and echocardiograms greater than heparin. Need for further double-blinded RCTs.

**Conclusion:** We cannot conclude whether thrombolytic therapy is better than heparin for pulmonary embolism based on limited evidence found.
Inferior Vena Cava Filter
- insertion of metallic “umbrellas” to mechanically trap emboli and prevent PE
- may be temporary (retrievable) or permanent
- inserted via femoral vein, jugular vein, or antecubital vein
- usually placed infrarenally to avoid renal vein thrombosis
- indications: contraindication to anticoagulation, failure of adequate anticoagulation (e.g. recurrent PE despite therapeutic anticoagulant levels), complication of anticoagulation

Central Venous Access
- variety of devices available
- PICC, external tunneled catheter (Hickman or dialysis catheters), subcutaneous port (Portacath®)
- indications: chemotherapy, TPN, long-term antibiotics, administration of fluids and blood products, blood sampling
- complications: venous thrombosis and central venous stenosis, infection including sepsis, pneumothorax

Nonvascular Interventions

Percutaneous Biopsy
- replaces open surgical procedure
- many sites are amenable to biopsy using U/S, fluoroscopy or CT guidance
- complications: false negative (sampling error or tissue necrosis), pneumothorax in 30% of lung biopsies (chest tube required in approximately 5%), acute pancreatitis (pancreatic biopsies), bleeding from liver biopsies in patients with uncorrectable coagulopathies or ascites (can be minimized with transjugular approach)

Abscess Drainage
- placement of a drainage catheter into an infected fluid collection
- administer broad spectrum IV antibiotics prior to procedure
- routes: percutaneous (most common), transgluteal, transvaginal, transrectal
- complications: hemorrhage, injury to intervening structures (e.g. bowel), bacteremia, sepsis

Percutaneous Biliary Drainage/Cholecystostomy
- placement of drainage catheter ± metallic stent into obstructed biliary system (PBD) or gallbladder (cholecystostomy) for relief of jaundice or infection
- percutaneous gallbladder access can be used to crush or remove stones
- indications
  - cholecystostomy: acute cholecystitis
  - PBD: biliary obstruction secondary to stone or tumor, cholangitis
- complications
  - acute: sepsis, hemorrhage
  - long-term: tumor overgrowth and stent occlusion

Percutaneous Nephrostomy
- placement of catheter into renal collecting system
- indications: hydronephrosis, pyonephrosis, ureteric injury with or without urinary peritonitis (traumatic or iatrogenic)
- complications: bacteria and septic shock, hematuria due to pseudoaneurysm or AV fistulas, injury to adjacent organs

Gastrostomy/Gastrojejunostomy
- percutaneous placement of catheter directly into either stomach (gastrostomy) or through stomach into small bowel (transgastric jejunostomy)
- indications: inability to eat (most commonly CNS lesion) or esophageal obstruction, decompression in gastric outlet obstruction
- complications: gastroesophageal reflux with aspiration, peritonitis, hemorrhage, bowel or solid organ injury

Radiofrequency Ablation
- U/S or CT guided probe is inserted into tumor, radiofrequency energy delivered through probe causes heat deposition and tissue destruction
- indications: hepatic tumors (HCC and metastases), renal tumors
- complications: destruction of neighbouring tissues and structures, bleeding

Figure 42. Retrievable IVC filter

Indications for Central Venous Access
- FAT CAB
- Fluids
- Antibiotics
- TPN
- Chemotherapy
- Administration of blood
- Blood sampling

Figure 43. Femoral arteriogram: distal occlusion of superficial femoral artery
Breast Imaging

Modalities

Mammography

Description
- x-ray imaging of the breasts for screening in asymptomatic patients, or diagnosis of clinically-detected or screening-detected abnormalities (see General Surgery, GS54)

Indications
- screening
  - begin screening from age 50 q1-2 yr
  - if over the age of 70, continue screening mammography if in good general health
  - not routinely recommended if under the age of 50 unless strong family history
  - if positive family history, begin screening 5-10 yr younger than the first degree relative who developed breast cancer
- diagnostic
  - signs and symptoms suggestive of breast cancer include a lump or thickening, localized nodularity, dimpling or contour deformity, a persistent focal area of pain, and spontaneous serous or sanguinous nipple discharge from a single duct
  - women with abnormal screening mammograms
  - follow-up of women with previous breast cancer
  - suspected complications of breast implants

Breast MRI

Description
- should be used only after mammography and U/S investigation
- sensitive for detecting invasive breast cancer (95-100%) but specificity variable (37-97%)
- use as a screening modality has been limited to high risk patients

Indications
- evaluation of previously diagnosed breast cancer: positive margins, recurrence, response to chemotherapy
- post-surgical resection of breast cancer
- known BRCA1 or BRCA2 mutation, or other gene predisposing to breast cancer
- untested first-degree relative of a carrier of such a gene mutation
- family history consistent with a hereditary breast cancer syndrome and estimated personal lifetime cancer risk >25%
- high-risk marker on prior biopsy (atypical ductal hyperplasia, atypical lobular hyperplasia, lobular carcinoma in situ)
- radiation therapy to chest (before age 30)
- MRI should not be used to screen the general population or to differentiate between benign and malignant lesions
**U/S**

**Definition**
- U/S can determine if a mass is cystic or solid and is commonly used during biopsy

**Indications**
- identification and characterization of palpable abnormalities
- evaluation of ambiguous mammographic findings in the determination of cystic vs. solid characteristics
- evaluation of patients with suspected silicone implant rupture and problems associated with breast implants
- guidance for interventional procedures
- breast U/S is the initial imaging technique to evaluate palpable masses in women under 30 and in lactating and pregnant women

## Breast Interventional Procedures

**Description**
- includes fine needle aspirate biopsy, core needle biopsy, abscess drainage, and cyst aspiration (see General Surgery, GS54)

**Indications**
- cystic mass: complex cyst, symptomatic, suspected abscess
- solid mass: confirm diagnosis of a lesion suspicious for malignancy (BI-RADS® Category 4 or 5) or confirm diagnosis of a probable benign mass (BI-RADS® Category 3)
- initial percutaneous biopsy procedure that was insufficient or discordant with imaging
- presurgical U/S-guided localization of a lesion

## Breast Findings

### Breast Masses
- definition: a space occupying lesion seen in two different projections; if seen in only a single projection it should be called a "density" until its three-dimensionality is confirmed

<table>
<thead>
<tr>
<th>Table 21. Mammographic Features of Benign and Malignant Breast Masses</th>

</thead>
<tbody>
<tr>
<td><strong>Benign</strong></td>
</tr>
<tr>
<td>Shape</td>
</tr>
<tr>
<td>Margin</td>
</tr>
<tr>
<td>Density</td>
</tr>
<tr>
<td>Calcifications (+ mass)</td>
</tr>
</tbody>
</table>

### Other Findings
- tubular density/dilated duct: branching tubular structures usually represent enlarged ducts (milk ducts); if they are clearly identified as such, these densities are of little concern
- intramammary lymph node: typical lymph nodes are circumscribed, reniform and often have a fatty notch and center; usually less than 1 cm, and usually seen in the outer, often upper part of the breast; when these characteristics (particularly fatty center or notch) are well seen, the lesion is almost always benign and insignificant
- focal asymmetric density: area of breast density with similar shape on two views, but completely lacking borders and conspicuity of a true mass; must be carefully evaluated with focal compression to exclude findings of a true mass or architectural distortion
  - if focal compression shows mass-like character, or if the area can be palpated, biopsy must be considered

Renal Structure and Function

The Nephron
- basic structural and functional unit of the kidney, approximately 1 million per kidney
- direction of blood flow: afferent arteriole → glomerular capillaries → efferent arteriole → vasa recta (the capillaries surrounding the tubules) → renal venules

</tbody>
</table>

The Glomerulus
- site where blood constituents are filtered through to the kidney tubules for excretion or reabsorption
- filtration occurs across the glomerular filtration barrier (endothelium, GBM, podocytes) into Bowman’s space
- particles are selectively filtered by size (<60 kDa) and charge (negative charge repelled)
- consists of following cell types
  1. Mesangial cells
     - structural cells that support the vascular tree; they are also contractile and produce vasoactive substances to help control blood flow
  2. Capillary endothelial cells
     - one of the cells of the glomerular filtration barrier and help form the plasma filtration apparatus due to their sinusoidal nature and glycocalyx; contribute to the production of the GBM
  3. Visceral epithelium (podocytes)
     - one of the cells of the glomerular filtration barrier and help form the plasma filtration apparatus due to their interdigitated foot process that form slit diaphragms; contribute to the production of the GBM
  4. Parietal epithelium
  5. Juxtaglomerular cells
     - smooth muscle cell in lining of afferent arteriole; produce, store, and secrete renin as part of renal autoregulation

**The Renal Tubules**

- reabsorption and secretion occur between the renal tubules and vasa recta forming urine for excretion
- each segment of the tubule selectively transports various solutes and water and is targeted by specific diuretics

---

**Renal Hemodynamic Parameters**

- RBF = 20% of CO, ~1 L/min
- RPF = RBF*(1-Hct)
- GFR = ~120 mL/min in healthy adult (99% of this volume is reabsorbed)
- FF = GFR/RPF (normally 20%)

---

**Figure 1. The glomerulus**

The Renal Tubules

- reabsorption and secretion occur between the renal tubules and vasa recta forming urine for excretion
- each segment of the tubule selectively transports various solutes and water and is targeted by specific diuretics
Renal Hemodynamics

- GFR
  - the rate of fluid transfer between glomerular capillaries and Bowman’s space
  - 180 L/d, of which 99% is reabsorbed, giving a daily urine output of 1.0-1.5 L
  - normal urine output is >0.5 ml/kg/h in adults
  - GFR is highest in early adulthood, and decreases thereafter
- renal autoregulation maintains constant GFR over mean arterial pressures of 70-180 mmHg
- 2 mechanisms of autoregulation:
  - myogenic mechanism: release of vasoactive factors in response to changes in perfusion pressure (e.g. ↑ perfusion pressure → afferent arteriolar constriction → ↓ GFR)
  - tubuloglomerular feedback: changes in Na⁺ delivery to macula densa lead to changes in afferent arteriolar tone (e.g. increased delivery causes afferent constriction)
- FF
  - percentage of RPF filtered across the glomeruli
  - expressed as a ratio: FF = GFR/RPF; normal = 0.2 or 20%
  - angiotensin II constricts renal efferent arterioles, which increases FF thereby maintaining GFR
- renin is released from juxtaglomerular apparatus in response to decreased RPF

Assessment of Renal Function

Measurement of Renal Function

- GFR = rate of filtration of plasma by the glomeruli
- most renal functions decline in parallel with a decrease in GFR
- inulin clearance is the gold standard for measuring GFR, but very rarely used clinically
- clinically, GFR is estimated using serum creatinine concentration, [Cr]
- Cr is a metabolite of creatine (intermediate in muscle energy metabolism)
- Cr is freely filtered at the glomerulus with no tubular reabsorption
- tubular secretion varies based on level of renal function (10% to >50%)
- rate of production determined by muscle mass
- Cr filtered = Cr excreted (at steady state)

Ways to Estimate GFR Using Serum Creatinine Concentration
1. Measure CrCl
   - calculation provides reasonable estimate of GFR
   - measure plasma [Cr], 24 h urine volume, and urine [Cr]
   - GFR/d = (urine [Cr] x urine volume/d)/(plasma [Cr])
   - must use same units for urine [Cr], and plasma [Cr]
2. Estimate CrCl using Cockcroft-Gault formula
   - serum Cr used along with age, gender, and weight (kg) to estimate GFR
   - normal range is >90 mL/min (>1.5 mL/s)

Cockcroft-Gault Formula
CrCl (mL/min) = \( \frac{[\text{Cr}]_{\text{plasma}} \times \text{urine flow rate}}{[\text{Cr}]_{\text{urea}}} \)

At steady state \([\text{Cr}]_{\text{plasma}} = \frac{1}{\text{CrCl}}\)

Cockcroft-Gault Formula
CrCl (mL/min) = \( \frac{\text{weight in kg} \times 1.23}{(\text{serum creatinine in } \mu\text{mol/L}) \times (140 - \text{age})} \)

Multiply above by 0.85 for females
3. Estimate GFR using MDRD formula
   - most common way in which GFR is estimated (MDRD 7 equation)
   - complex formula incorporating age, gender, serum Cr, and African descent, but does not include weight
   - GFR is reported as mL/min/1.73 m² body surface area

4. Estimate GFR using CKD-EPI equation
   - the best current equation
   - calculated using serum Cr, age, sex, and race

Limitations of Using Serum Cr Measurements
1. must be in steady state
   - constant GFR and rate of production of Cr from muscles
   - sudden injury may reduce GFR substantially, but it takes time for Cr to accumulate and then re-establish steady state
   - clinical correlation: in AKI, the rise in Cr is often delayed
2. GFR must fall substantially before plasma [Cr] rises above normal laboratory range
   - with progressive renal failure, remaining nephrons compensate with hyperfiltration
   - GFR is relatively preserved despite significant structural damage
3. plasma [Cr] is influenced by the rate of Cr production
   - lower production with smaller muscle mass (e.g. female, elderly, low weight)
   - for example, consider plasma [Cr] of 100 µmol/L (1.13 mg/dL) in both of these patients
     - 20 yr old man who weighs 100 kg, GFR = 144 mL/min
     - 80 yr old woman who weighs 50 kg, GFR = 30.6 mL/min
   - clinical correlation: GFR decreases with age but would not be reflected as a rise in serum Cr due to the age-associated decline in muscle mass
4. tubular secretion of Cr increases as GFR decreases
   - serum Cr and CrCl overestimate low GFR
   - certain drugs (cimetidine, trimethoprim) interfere with Cr secretion
5. errors in Cr measurement
   - very high bilirubin level causes [Cr] to be falsely low
   - acetooacetate (a ketone body) and certain drugs (cefoxitin) create falsely high [Cr]

Measurement of Urea Concentration
- urea is the major end-product of protein metabolism
- plasma urea concentration reflects renal function but should not be used alone as it is modified by a variety of other factors
- urea production reflects dietary intake of protein and catabolic rate; increased protein intake or catabolism (sepsis, trauma, GI bleed) causes urea level to rise
- ECF volume depletion causes a rise in urea independent of GFR or plasma [Cr]
- in addition to filtration, a significant amount of urea is reabsorbed along the tubule
- reabsorption is increased in hypernatremic states such as ECF volume depletion
- typical ratio of urea to [Cr] in serum is 1:12 in SI units (using mEq/L for urea and µmol/L for Cr)

Urinalysis
- use dipstick in freshly voided urine specimen to assess the following:

1. Specific Gravity
   - ratio of the mass of equal volumes of urine/H₂O
   - range is 1.001 to 1.030
   - values <1.010 reflect dilute urine, values >1.020 reflect concentrated urine
   - value usually 1.010 in ESRD (isosthenuria)

2. pH
   - urine pH is normally between 4.5-7.0; if persistently alkaline, consider:
     - RTA
     - UTI with urease-producing bacteria (e.g. Proteus)

3. Glucose
   - freely filtered at glomerulus and reabsorbed in proximal tubule
   - causes of glucosuria include
     1. hyperglycemia >160-200 mg/dL (>9.11 mEq/L) leads to filtration that exceeds tubular resorption capacity
     2. increased GFR (e.g. pregnancy)
     3. proximal tubule dysfunction (e.g. Fanconi’s syndrome)

4. Protein
   - dipstick only detects albumin; other proteins (e.g. Bence-Jones, Ig, Tamm-Horsfall) may be missed
   - microalbuminuria (defined as ≥2.0 mg/mEq Cr in males and ≥2.8 mg/mEq Cr in females) is not detected by standard dipstick (see Diabetes, NP28)
   - sulfosalicylic acid detects all protein in urine by precipitation
   - gold standard: 24 h timed urine collection for total protein
5. **Leukocyte Esterase**
- enzyme found in WBC and detected by dipstick
- presence of WBCs indicates infection (e.g. UTI) or inflammation (e.g. AIN)

6. **Nitrites**
- nitrates in urine are converted by some bacteria to nitrites
- high specificity, low sensitivity for UTI

7. **Ketones**
- positive in alcoholic/diabetic ketoacidosis, prolonged starvation, fasting

8. **Hemoglobin**
- positive in hemoglobinuria (hemolysis), myoglobinuria (rhabdomyolysis), and true hematuria
  (RBCs seen on microscopy)

### Urine Microscopy

- centrifuge urine specimen for 3-5 min, discard supernatant, resuspend sediment and plate on slide
- shaking tube vigorously may disrupt casts

#### Table 2. Comparison of Urinary Sediment Findings

<table>
<thead>
<tr>
<th>Active Sediment = Suggestive of Parenchymal Kidney Disease</th>
<th>Bland Sediment = Less Likely Parenchymal Kidney Disease</th>

<td>Small quantities of crystals</td>
</tr>
<tr>
<td>&gt;4 white cells per HPF</td>
<td>Small amount of bacteria</td>
</tr>
</tbody>
</table>

1. **CELLS**

**Erythrocytes**
- normal range = up to 2-3 RBCs per HPF
- hematuria = greater than 2-3 RBCs per HPF
- dysmorphic RBCs and/or RBC casts suggest glomerular bleeding (e.g. proliferative GN)
- isomorphic RBCs, no casts suggest extraglomerular bleeding (e.g. bladder Ca)

**Leukocytes**
- normal range = up to 3 WBCs per HPF
- pyuria = greater than 3 WBCs per HPF
- indicates inflammation or infection
- if persistent sterile pyuria present (i.e. negative culture), consider: chronic urethritis, prostatitis, interstitial nephritis, calculi, papillary necrosis, renal TB, viral infections

**Eosinophils**
- detected using Wright's or Hansel's stain (not affected by urine pH)
- consider AIN, atheroembolic disease

**Oval Fat Bodies**
- renal tubular cells filled with lipid droplets
- seen in heavy proteinuria (e.g. nephrotic syndrome)

2. **CASTS**

- cylindrical structures formed by intratubular precipitation of Tamm-Horsfall mucoprotein; cells may be trapped within the matrix of protein

#### Table 3. Interpretation of Casts

</tbody>
</table>
3. CRYSTALS
- uric acid: consider acid urine, hyperuricosuria
- calcium phosphate: alkaline urine
- calcium oxalate: consider hyperoxaluria, ethylene glycol poisoning
- sulfates: sulfat-containing antibiotics

**Urine Biochemistry**
- commonly measure: Na⁺, K⁺, Cl⁻, osmolality, and pH
- no ‘normal’ values; electrolyte excretion depends on intake and current physiological state
- results must be interpreted in the context of a patient’s current state
  1. ECF volume depletion: expect low urine [Na⁺] (kidneys should be retaining Na⁺)
     - urine [Na⁺] (>40 mEq/L) suggests a renal problem or the action of a diuretic
     - urine [Na⁺] (<20 mEq/L) suggests a prerenal problem
  2. daily urinary potassium excretion rate should be decreased (<20 mEq/d) in hypokalemia
     - if higher than 20 mEq/d, suggests renal contribution to hypokalemia
- osmolality is useful to estimate the kidney’s concentrating ability
  - FENa refers to the fractional excretion of Na⁺
    - FENa = urine [Na⁺] x plasma [Cr] / (plasma [Na⁺] x urine [Cr])
    - FENa <1% suggests the pathology is prerenal

**Examples of Common Urine Electrolyte Abnormalities**
- high urine [Na⁺] (>40 mEq/L) in the setting of AKI: suggests renal disease
- high urine [Na⁺] (>40 mEq/L) in the setting of hyponatremia: generally from causes such as diuretics, tubular disease (e.g. Bartter’s syndrome), SIADH
- additionally, urine pH is useful to grossly assess renal acidification
  - low pH (<5.5) in the presence of low serum pH is an appropriate renal response
  - a high pH in this setting might indicate a renal acidification defect (e.g. RTA)

**Sodium Homeostasis**
- hyponatremia and hypernatremia are disorders of water balance
  - hyponatremia usually suggests too much water in the ECF relative to Na⁺
  - hypernatremia usually suggests too little water in the ECF relative to Na⁺
- solutes (such as Na⁺, K⁺, glucose) that cannot freely traverse the plasma membrane contribute to effective osmolality and induce transcellular shifts of water
  - water moves out of cells in response to increased ECF osmolality
  - water moves into cells in response to decreased ECF osmolality
- ECF volume is determined by Na⁺ content rather than concentration
  - Na⁺ deficiency leads to ECF volume contraction
  - Na⁺ excess leads to ECF volume expansion
- clinical signs and symptoms of hyponatremia and hypernatremia are secondary to cells (especially in the brain) shrinking (hyponatremia) or swelling (hypernatremia)

*If there is a renal abnormality (e.g. osmotic diuresis), the urine output may be increased despite the presence of hypovolemia
Hyponatremia

- hyponatremia: serum $[\text{Na}^+] < 135 \text{ mEq/L}$
- can be associated with hypo-osmolality (most common), iso-osmolality, or hyperosmolality
- consider if it is "appropriate" vs. "inappropriate" ADH secretion
- if appropriate ADH secretion, is it real vs. effective volume loss?

**Figure 4. Approach to hyponatremia**

**Signs and Symptoms**
- depend on degree of hyponatremia and more importantly, velocity of progression from onset
- acute hyponatremia (<24-48 h) more likely to be symptomatic
- chronic hyponatremia (>24-48 h) less likely to be symptomatic due to adaptation
  - adaptation: normalization of brain volume through loss of cellular electrolytes (within hours) and organic osmolytes (within days)
  - adaptation is responsible for the risks associated with overly rapid correction
- neurologic symptoms predominate (secondary to cerebral edema): headache, nausea, malaise, lethargy, weakness, muscle cramps, anorexia, somnolence, disorientation, personality changes, depressed reflexes, decreased LOC

**Complications**
- seizures, coma, respiratory arrest, permanent brain damage, brainstem herniation, death
- risk of brain cell shrinkage with rapid correction of hyponatremia
  - can develop osmotic demyelination of pontine and extrapontine neurons; may be irreversible (e.g. central pontine myelinolysis: cranial nerve palsies, quadriplegia, decreased LOC)

**Risk Factors for Osmotic Demyelination**
- rise in serum $[\text{Na}^+]$ with correction $>8 \text{ mEq/L/d}$ if chronic hyponatremia
- associated hypokalemia
- if patient with hyponatremia and hypovolemia is given large volumes of isotonic fluids (e.g. mannitol)
  - may develop osmotic demyelination of pontine and extrapontine neurons; may be irreversible (e.g. central pontine myelinolysis: cranial nerve palsies, quadriplegia, decreased LOC)

**Investigations**
- ECF volume status assessment (see Table 4)
- serum electrolytes, glucose, Cr
- serum osmolality, urine osmolality
- urine $\text{Na}^+$ (urine $\text{Na}^+$ <10-20 mEq/L suggests volume depletion as the cause of hyponatremia)
- assess for causes of SIADH (see Table 6)
- TSH, free T4, and cortisol levels
- consider CXR and possibly CT chest if suspect pulmonary cause of SIADH (e.g. small cell lung cancer)
- consider CT head if suspect CNS cause
Treatment of Hyponatremia
• general measures for all patients
  1) treat underlying cause (e.g. restore ECF volume if volume depleted, remove offending
drug, treat pain, nausea, etc.)
  2) restrict free water intake
  3) promote free water loss
  4) carefully monitor serum Na⁺, urine volume, and urine tonicity (e.g. high output of dilute
    urine may be a sign of impending rapid serum sodium correction)
  5) frequently ensure correction is not occurring too rapidly
    • monitor urine output frequently: high output of dilute urine is the first sign of
dangerously rapid correction of hyponatremia

A. Definitely Acute (known to have developed over <24-48 h)
• commonly occurs in hospital (dilute IV fluid, post-operative increased ADH)
• less risk from rapid correction since adaptation has not fully occurred
• if symptomatic
  • correct rapidly with 3% NaCl 1-2 cc/kg/h up to serum [Na⁺] = 125-130 mEq/L
  • may need furosemide to address volume overload
• if asymptomatic, treatment depends on severity
  • if marked fall in plasma [Na⁺], treat as symptomatic

B. Chronic or Unknown
  1. if severe symptoms (seizures or decreased LOC)
    • must partially correct acutely
    • aim for increase of Na⁺ by 1-2 mEq/L/h for 4-6 h
    • limit total rise to 8 mEq/L in 24 h
    • IV 3% NaCl at 1-2 cc/kg/h
    • may need furosemide
  2. if asymptomatic
    • water restrict to <1 L/d fluid intake
    • consider IV 0.9% NaCl + furosemide (reduces urine osmolality, augments excretion of H₂O)
    • consider NaCl tablet
  3. refractory
    • furosemide and oral salt tablets
    • oral urea (osmotic aquaresis)
    • V2 receptor antagonists (e.g. tolvaptan)
  4. always pay attention to patient’s ECF volume status – if already volume-expanded, unlikely to
give NaCl; if already volume-depleted, almost never appropriate to give furosemide

C. Options for Treatment of Overly-Rapid Correction
• give water (IV D5W)
• give ADH to stop water diuresis (DDAVP 1-2 µg IV)

Impact of IV Solution on Serum [Na⁺]
• formula to estimate the change in serum [Na⁺] caused by retention of 1 L of any infusate
  [TBW = (for men) 0.6 x wt(kg); (for women) 0.5 x wt(kg)]

  TBW + 1 L

• formula assumes there are no losses of water or electrolytes

SYNDROME OF INAPPROPRIATE ANTI DiURETIC HORMONE SECRETION
1. urine that is inappropriately concentrated for the serum osmolality
2. high urine sodium (>20-40 mEq/L)
3. high FEₙₐ

Hypernatremia

- hypernatremia: serum [Na⁺] >145 mEq/L
- too little water relative to total body Na⁺; always a hyperosmolar state
- usually due to NET water loss, rarely due to hypertonic Na⁺ gain
- less common than hyponatremia because patients are protected against hypernatremia by thirst and release of ADH

Figure 5. Approach to hypernatremia

Signs and Symptoms
- with acute hypernatremia no time for adaptation, therefore more likely to be symptomatic
- adaptive response: cells import and generate new osmotically active particles to normalize size
- due to brain cell shrinkage: altered mental status, weakness, neuromuscular irritability, focal neurologic deficits, seizures, coma, death
- ± polyuria, thirst, signs of hypovolemia

Complications
- increased risk of vascular rupture resulting in intracranial hemorrhage
- rapid correction may lead to cerebral edema due to ongoing brain hyperosmolality

Treatment of Hypernatremia
- general measures for all patients
  - give free water (oral or IV)
  - treat underlying cause
  - monitor serum Na⁺ frequently to ensure correction is not occurring too rapidly
- if evidence of hemodynamic instability, must first correct volume depletion with NS bolus
- loss of water is often accompanied by loss of Na⁺, but a proportionately larger water loss
- use formula to calculate free water H₂O deficit and replace
- encourage patient to drink pure water, as oral route is preferred for fluid administration
- if unable to replace PO or NG, correct H₂O deficit with hypotonic IV solution (IV D5W, 0.45% NS [half normal saline], or 3.3% dextrose with 0.3% NaCl [“2/3 and 1/3”])
- use formula (see Hyponatremia, NP8) to estimate expected change in serum Na⁺ with 1 L infusate
- aim to to lower [Na⁺] by no more than 12 mEq/L in 24 h (0.5 mEq/L/h)
- must also provide maintenance fluids and replace ongoing losses
- general rule: give 2 cc/kg/h of free water to correct serum [Na⁺] by about 0.5 mEq/L/h or 12 mEq/L/d

H₂O Deficit and TBW Equations
- TBW = 0.6 x wt (kg) men
- TBW = 0.5 x wt (kg) women
- H₂O deficit = TBW x ([(Na⁺)plasma – 140] / 140)

Correction of serum (Na⁺) in hypernatremia should not exceed 12 mEq/L/24 h
1 L D5W approximately equals 1 L of free water
1 L 0.45% NS approximately equals 500 mL of free water

1 L D5W approximately equals 1 L of free water
DIABETES INSIPIDUS
- collecting tubule is impermeable to water due to absence of ADH or impaired response to ADH
- defect in central release of ADH (central DI) or renal response to ADH (nephrogenic DI)

Etiology
- central DI: neurosurgery, granulomatous diseases, trauma, vascular events, and malignancy
- nephrogenic DI: lithium (most common), hypokalemia, hypercalcemia, and congenital

Diagnosis
- urine osmolality inappropriately low in patient with hypernatremia (U_{osm} < 300 mOsm/kg)
- serum vasopressin concentration may be absent, low (central), or elevated (nephrogenic)
- dehydration test: H₂O deprivation until loss of 3% of body weight or until urine osmolality rises above plasma osmolality; if urine osmolality remains < 300 (fails to concentrate urine), most likely DI
- administer DDAVP (exogenous ADH) (10 µg intranasally or 2 µg SC or IV)
  - central DI: diagnosed if there is rise in urine osmolality, fall in urine volume
  - treat with DDAVP
  - nephrogenic DI: exogenous ADH fails to concentrate urine as kidneys do not respond
  - treat with water (IV D5W or PO water), thiazides may help as well (reduced ECF volume stimulates proximal tubular reabsorption of sodium and water, leading to less delivery of glomerular filtrate to ADH sensitive parts of renal tubule, and therefore lower urine volume results)

Potassium Homeostasis
- approximately 98% of total body K⁺ stores are intracellular
- normal serum K⁺ ranges from 3.5-5.0 mEq/L
- in response to K⁺ load, rapid removal from ECF is necessary to prevent life-threatening hyperkalemia
- insulin, catecholamines, and acid-base status influence K⁺ movement into cells
  - aldosterone has a minor effect
- potassium excretion is regulated at the distal nephron
  - K⁺ excretion = urine flow rate x urine [K⁺]

Factors which Increase Renal K⁺ Loss
- hyperkalemia
- increased distal tubular urine flow rate and Na⁺ delivery (thiazides and loop diuretics)
- increased aldosterone activates epithelial sodium channel in cortical collecting duct, causing Na⁺ reabsorption and K⁺ excretion
- metabolic alkalosis
- hypomagnesemia
- increased non-reabsorbable anions in tubule lumen: HCO₃⁻, penicillin, salicylate

Hypokalemia
- serum [K⁺] < 3.5 mEq/L

Signs and Symptoms
- usually asymptomatic, particularly when mild (3.0-3.5 mEq/L)
- N/V, fatigue, generalized weakness, myalgia, muscle cramps, and constipation
- if severe: arrhythmias, muscle necrosis, and rarely paralysis with eventual respiratory impairment
- arrhythmias occur at variable levels of K⁺; more likely if digoxin use, hypomagnesemia, or CAD
- ECG changes are more predictive of clinical picture than serum [K⁺]
  - U waves most important (low amplitude wave following a T wave)
  - flattened or inverted T waves
  - depressed ST segment
  - prolongation of Q-T interval
  - with severe hypokalemia: P-R prolongation, wide QRS, arrhythmias; increases risk of digitalis toxicity

Figure 6. ECG changes in hypokalemia
Approach to Hypokalemia
1. emergency measures: obtain ECG; if potentially life threatening, begin treatment immediately
2. rule out transcellular shifts of K⁺ as cause of hypokalemia
3. assess contribution of dietary K⁺ intake
4. spot urine K:Cr (should be less than 1 in setting of hypokalemia)
   - if <1 consider GI loss
   - if >1 consider a renal loss
5. consider 24 h K⁺ excretion
6. if renal K⁺ loss, check BP and acid-base status
7. may also assess plasma renin and aldosterone levels, serum [Mg²⁺]

Figure 7. Approach to hypokalemia

Treatment
- treat underlying cause
- if true K⁺ deficit, potassium repletion (decrease in serum [K⁺] of 1 mEq is roughly 100-200 mEq of total body loss)
- oral sources – food, tablets (K-Tab™), KCl liquid solutions; preferable route if the patient tolerates PO medications
- IV – usually KCl in saline solutions, avoid dextrose solutions (may exacerbate hypokalemia via insulin release)
- max 40 mEq/L via peripheral vein, 60 mEq/L via central vein, max infusion 20 mEq/h
- K⁺-sparring diuretics (triamterene, spironolactone, amiloride) can prevent renal K⁺ loss
- restore Mg²⁺ if necessary
- if urine output and renal function are impaired, correct with extreme caution
- risk of hyperkalemia with potassium replacement especially high in elderly, diabetics, and patients with decreased renal function
- beware of excessive potassium repletion, especially if transcellular shift caused hypokalemia

Hyperkalemia
- serum [K⁺] >5.0 mEq/L

Signs and Symptoms
- usually asymptomatic but may develop nausea, palpitations, muscle weakness, muscle stiffness, paresthesias, areflexia, ascending paralysis, and hypoventilation
- impaired renal ammoniagenesis and metabolic acidosis
• ECG changes and cardiotoxicity (do not correlate well with serum [K⁺])
  ▪ peaked and narrow T waves
  ▪ decreased amplitude and eventual loss of P waves
  ▪ prolonged PR interval
  ▪ widening of QRS and eventual merging with T wave (sine-wave pattern)
  ▪ AV block
  ▪ ventricular fibrillation, asystole

Figure 8. ECG changes in hyperkalemia

<td>K⁺-sparing drugs • Spironolactone • Amiloride • Triamterene Renal tubulointerstitial disease</td>
</tr>
</tbody>
</table>

Approach to Hyperkalemia
1. emergency measures: obtain ECG, if life threatening begin treatment immediately
2. rule out factitious hyperkalemia; repeat blood test
3. hold exogenous K⁺ (PO and IV) and any K⁺ retaining medications
4. assess potential causes of transcellular shift
5. estimate GFR (calculate CrCl using Cockcroft-Gault)

Treatment
• acute therapy is warranted if ECG changes are present, or if patient is symptomatic
• tailor therapy to severity of increase in [K⁺] and ECG changes
  ▪ [K⁺] <6.5 and normal ECG
    • treat underlying cause, stop K⁺ intake, increase the loss of K⁺ via urine and/or GI tract
  ▪ [K⁺] between 6.5 and 7.0, no ECG changes: add insulin to above regimen
  ▪ [K⁺] >7.0 and/or ECG changes: first priority is to protect the heart, add calcium gluconate to above

1. Protect the Heart
• calcium gluconate 1–2 amps (10 mL of 10% solution) IV
• antagonizes cardiac toxicity of hyperkalemia, protects cardiac conduction system, no effect on serum [K⁺]
• onset within minutes, lasts 30–60 min (may require repeat doses during treatment course of hyperkalemia)
2. Shift K⁺ into Cells
- regular insulin (Insulin R) 10-20 units IV, with 1-2 amp D50W (give D50W before insulin)
  - onset of action 15-30 min, lasts 1-2 h
  - monitor capillary blood glucose q1h because of risk of hypoglycemia
  - can repeat every 4-6 h
  - caution giving D50W before insulin if hyperkalemia is severe as it can cause a serious arrhythmia
- NaHCO₃ 1-3 ampules (given as 3 ampules of 7.5% or 8.4% NaHCO₃ in 1L D5W)
  - onset of action 15-30 min, transient effect, drives K⁺ into cells in exchange for H⁺
  - more effective if patient has metabolic acidosis
- β₂-agonist (Ventolin®) in nebulized form (dose = 2 cc or 10 mg inhaled) or 0.5 mg IV
  - onset of action 30-90 min, stimulates Na⁺/K⁺ ATPase
  - caution if patient has heart disease as may result in tachycardia

3. Enhance K⁺ Removal from Body
- via urine (preferred approach)
  - furosemide (≥40 mg IV), may need IV NS to avoid hypovolemia
  - fludrocortisone (synthetic mineralocorticoid) if suspect aldosterone deficiency
- via gastrointestinal tract
  - cation-exchange resins: calcium resinomium or sodium polystyrene sulfonate (Kayexalate®)
    - increasingly falling out of favor due to risk of colonic necrosis; works by binding Na⁺ in exchange for K⁺, and controversial how much K⁺ is actually removed
  - lactulose PO to avoid constipation (must ensure that patient has a bowel movement after resin is administered – main benefit may be the diarrhea caused by lactulose)
  - Kayexalate® enemas with tap water
- dialysis (renal failure, life threatening hyperkalemia unresponsive to therapy)

Acid-Base Disorders
- acid-base homeostasis influences protein function and can critically affect tissue and organ function with consequences to cardiovascular, respiratory, metabolic, and CNS function
- see Respiriology, R5 for more information on respiratory acidosis/alkalosis
  - normal concentration of HCO₃⁻ = 24 mEq/L (range: 22-30)
  - normal pCO₂ = 40 mmHg (range: 36-44)
- each acid base disorder has an appropriate compensation
  - inadequate compensation or overcompensation can indicate the presence of a second acid-base disorder (e.g. in metabolic acidosis, inadequate compensation means there is also respiratory acidosis; overcompensation means there is also respiratory alkalosis)

Figure 9. Approach to acid-base disorders

**Approach**

1. **Identify the primary disturbance** (see Figure 8)
   - respiratory acidosis, metabolic acidosis, respiratory alkalosis, metabolic alkalosis
2. Evaluate compensation. If compensation is not appropriate, a second acid-base disorder is likely present
- compensation occurs in the same direction as the primary disturbance
- metabolic acidosis: for every 1 mEq/L decrease in HCO₃⁻, pCO₂ should decrease by 1 mmHg
- metabolic alkalosis: for every 10 mEq/L increase in HCO₃⁻, pCO₂ should increase by 5-7 mmHg
- respiratory acidosis: for every 10 mmHg increase in pCO₂, HCO₃⁻ should increase by 1 (acute) or 3 (chronic) mEq/L
- respiratory alkalosis: for every 10 mmHg decrease in pCO₂, HCO₃⁻ should decrease by 2 (acute) or 5 (chronic) mEq/L

3. Calculate Plasma AG
- \( AG = [Na^+] - ([HCO_3^-] + [Cl^-]) \)
- baseline = 12, range 10-14 mEq/L
- AG can be altered by plasma albumin level: for each 10 g/L fall in albumin, lower baseline AG by 3 mEq/L (e.g. if plasma [albumin]= 20 g/L, expect AG = 6 mEq/L)

4. If AG elevated, compare increase in AG with decrease in HCO₃⁻
- if increase in AG < decrease in HCO₃⁻, there is a coexisting non-AG metabolic acidosis
- if increase in AG > decrease HCO₃⁻, there is a coexisting metabolic alkalosis

5. Calculate Osmolar Gap
- osmolar gap = measured osmolality – calculated osmolality
- calculated osmolality = \( 2[Na^+] + [BUN]/2.8 + [glucose]/18 \) (all units are in mEq/L)
- normal osmolar gap <10
- if AG >10, consider: methanol poisoning, ethylene glycol poisoning, or another cause of acidosis plus ethanol ingestion

### Metabolic Acidosis

#### Etiology and Pathophysiology

1. Increased AG Metabolic Acidosis (4 types)
   a. L-lactic acid
      - Type A: due to tissue hypoperfusion (any cause of shock), ischemic bowel, profound hypoxemia
      - Type B: non-hypoxic – multiple causes; the most common is failure to metabolize normally produced lactic acid in the liver due to severe liver disease; other causes include: excessive alcohol intake, thiamine deficiency, metformin accumulation (metformin interferes with electron transport chain), certain antiretrovirals, large tumours, mitochondrial myopathies
    - D-lactic acid: rare syndrome characterized by episodes of encephalopathy and metabolic acidosis
      - occurs in the setting of carbohydrate malabsorption (e.g. short bowel syndrome), colonic bacteria metabolize carbohydrate load into D-lactic acid, diminished colonic motility and impaired D-lactate metabolism
   b. Ketoacidosis
      - diabetic
      - starvation
      - alcoholic (decreased carbohydrate intake and vomiting)
   c. Toxins
      - methanol (toxic to brain and retina, can cause blindness and brain death): metabolized to formic acid
      - ethylene glycol (toxic to brain and kidneys): metabolized to oxalic acid (envelope shaped crystals in urine) and multiple other acids
      - salicylate (e.g. ASA) overdose: causes acidosis due to salicylic acid, and also accumulation of lactic acid (salicylate at toxic levels impairs electron transport chain) and ketoacid (salicylate activates fat breakdown)
   d. Advanced renal failure (e.g. serum Cr increased at least 5x above baseline – a very low GFR causes anion retention, and renal disease leads to impaired bicarbonate production)

2. Normal AG Metabolic Acidosis (Hyperchloremic Acidosis)
   - diarrhea (HCO₃⁻ loss from GI tract)
   - RTA
      - type I RTA (distal): inability to secrete H⁺ in collecting duct, leading to impaired excretion of ammonium into urine
      - type II RTA (proximal): impaired HCO₃⁻ reabsorption
      - type IV RTA: defective ammoniagenesis due to decreased aldosterone, hyporesponsiveness or hyperkalemia
• to help distinguish renal causes from non-renal causes, use UAG = (Na⁺ + K⁺) – Cl⁻
  - if UAG < 0, suggests adequate NH₄⁺ excretion in urine (likely nonrenal cause: diarrhea)
  - if UAG > 0, suggests problem is lack of NH₄⁺ in urine (e.g. distal RTA)

Treatment of Metabolic Acidosis
• treat underlying cause
  - insulin for DKA
  - ethanol/fomepizole + dialysis for methanol or ethylene glycol poisoning
  - alkaline diuresis ± dialysis if ASA overdose
• correct coexisting disorders of K⁺ (see Hyperkalemia, NP12)
• consider treatment with exogenous alkali (e.g. NaHCO₃) if
  - severe reduction in [HCO₃⁻] e.g. <8 mEq/L, especially with very low pH (<7)
  - no metabolizable anion (e.g. salicylate, formate, oxalate, or sulphate); note that lactate and ketoacid anions can be metabolized to HCO₃⁻
• risks of sodium bicarbonate therapy
  - hypokalemia: causes K⁺ to shift into cells (correct K⁺ deficit first)
  - ECF volume overload: Na⁺ load given with NaHCO₃ can exacerbate pulmonary edema
  - overshoot alkalosis: abrupt, poorly tolerated transition from overly aggressive alkali loading, partial conversion of accumulated organic anions to HCO₃⁻, and persisting hyperventilation

Metabolic Alkalosis

Pathophysiology
• requires initiating event and maintenance factors
• precipitating factors
  - GI (vomiting, NG tube) or renal loss of H⁺
  - exogenous alkali (oral or parenteral administration), milk alkali syndrome
  - diuretics (contraction alkalosis): decreased excretion of HCO₃⁻, decreased ECF volume, therefore increased [HCO₃⁻]
  - post-hypercapnia: renal compensation for respiratory acidosis is HCO₃⁻ retention, rapid correction of respiratory disorder results in transient excess of HCO₃⁻
• maintenance factors
  - volume depletion: increased proximal reabsorption of NaHCO₃ and increased aldosterone
  - hyperaldosteronism (1º or 2º): distal Na⁺ reabsorption in exchange for K⁺ and H⁺ excretion leads to HCO₃⁻ generation; aldosterone also promotes hypokalemia
  - hypokalemia: transcellular K⁺/H⁺ exchange, stimulus for ammoniagenesis, and HCO₃⁻ generation

Figure 10. Approach to metabolic alkalosis

Evaluate Compensation (identify co-existing respiratory acid-base disorders)
• hypoventilation (an upper limit to compensation exists – breathing cannot be stopped)

Treatment
• treat underlying cause
• correct underlying disease, replenish K⁺ and Mg²⁺ deficits, and possibly K⁺-sparing diuretic
• saline sensitive metabolic alkalosis (most common)
  ▪ volume repletion ± carbonic anhydrase inhibitor (e.g. acetazolamide) to facilitate loss of
    \( \text{HCO}_3^- \) in urine
• saline resistant metabolic alkalosis
  ▪ remove source of aldosterone or glucocorticoid ± spironolactone

## Parenchymal Kidney Diseases

### Vascular Diseases of the Kidney

#### LARGE VESSEL DISEASE

<table>
<thead>
<tr>
<th>Large Vessel Disease</th>
<th>Small Vessel Disease</th>
</tr>
</thead>
<tbody>
<tr>
<td>Acute renal artery occlusion (infarct)</td>
<td>Hypertensive nephrosclerosis</td>
</tr>
<tr>
<td>Renal artery stenosis (ischemia)</td>
<td>Atheroembolic renal disease</td>
</tr>
<tr>
<td>Renal vein thrombosis</td>
<td>Thrombotic microangiopathy</td>
</tr>
<tr>
<td></td>
<td>Scleroderma</td>
</tr>
<tr>
<td></td>
<td>Calcineurin inhibitor nephropathy</td>
</tr>
</tbody>
</table>

1. **RENAL INFARCTION (ACUTE RENAL ARTERY OCCLUSION)**
   • important, potentially reversible cause of renal failure

**Etiology**
- abdominal trauma, surgery, embolism, vasculitis, extra-renal compression, hypercoagulable state, aortic dissection
- kidney transplant more vulnerable

**Signs and Symptoms (depend on presence of collateral circulation)**
- fever, N/V, flank pain
- leukocytosis, elevated AST, ALP
- marked elevated LDH (LDH >4x upper limit of normal with minimal elevations in AST/ALT strongly suggestive)
- acute onset HTN (activation of RAAS) or sudden worsening of long-standing HTN
- renal dysfunction, e.g. elevated Cr (if bilateral, or solitary functioning kidney)

**Investigations**
- renal arteriography (more reliable but risk of atheroembolic renal disease)
- contrast-enhanced CT or MR angiography, duplex Doppler studies (operator dependent)

**Treatment**
- prompt localization of occlusion and restoration of blood flow
- anticoagulation, thrombolysis, percutaneous angioplasty or clot extraction, surgical thrombectomy
- medical therapy in the long-term to reduce risk (e.g. antihypertensives)

2. **ISCHEMIC RENAL DISEASE (RENAL ARTERY STENOSIS)**
   • chronic renal impairment secondary to hemodynamically significant renal artery stenosis or microvascular disease
   • significant cause of ESRD: 15% in patients over 50 yr old (higher prevalence if significant vascular disease)
   • usually associated with large vessel disease elsewhere
   • causes of renal artery stenosis
     ▪ atherosclerotic plaques (90%): proximal 1/3 renal artery, usually males >55 yr, smokers
       - electrolytes, osmolality (gently rehydrate when needed, e.g. CHF)
     ▪ fibromuscular dysplasia (10%): distal 2/3 renal artery or segmental branches, usually young females (typical onset <30 yr) (gently rehydrate when needed, e.g. CHF)
   • when there is decreased RBF, GFR is dependent on angiotensin II-induced efferent arteriolar constriction which raises the FF (GFR/RBF)
   • most common cause of secondary HTN ("renovascular HTN"), 1-2% of all hypertensive patients
   • etiology
     ▪ decreased renal perfusion of one or both kidneys leads to increased renin release and subsequent angiotensin production
     ▪ increase angiotensin raises blood pressure in two ways
       1. causes generalized arteriolar constriction
       2. release of aldosterone increases Na\(^+\) and water retention
   • elevated blood pressure can in turn lead to further damage of kidneys and worsening HTN
Risk Factors
- >50 yr old
- smoking
- other atherosclerotic disease (dyslipidemia, DM, diffuse atherosclerosis)

Signs and Symptoms
- severe/refractory HTN and/or hypertensive crises, with negative family history of HTN
- asymmetric renal size
- epigastric or flank bruits
- spontaneous hypokalemia (renin activation in under-perfused kidney)
- increasing Cr with ACEI/ARB
- flash pulmonary edema with normal LV function

Investigations
- must establish presence of renal artery stenosis and prove it is responsible for renal dysfunction
- duplex Doppler U/S (kidney size, blood flow): good screening test (operator dependent)
- digital subtraction angiography (risk of contrast nephropathy)
- CT or MR angiography (effective noninvasive tests to establish presence of stenosis, for MR avoid gadolinium contrast if eGFR <30 mL/min because of risk of systemic dermal fibrosis)
- ACEI renography (e.g. captopril renal scan)
- renal arteriography (gold standard)

Treatment
- surgical: percutaneous angioplasty ± stent, surgical revascularization, occasionally surgical bypass
- medical: BP lowering medications (ACEI is drug of choice if unilateral renal artery disease but contraindicated if bilateral renal artery disease)
- little or no benefit if therapy is late (e.g. kidney is already shrunken), however, therapy can be considered to save the opposite kidney if normal

3. RENAL VEIN THROMBOSIS

Etiology
- hypercoagulable states (e.g. nephrotic syndrome, especially membranous), ECF volume depletion, extrinsic compression of renal vein, significant trauma, malignancy (e.g. RCC), sickle cell disease
- clinical presentation determined by rapidity of occlusion and formation of collateral circulation

Signs and Symptoms
- acute: N/V, flank pain, hematuria, elevated plasma LDH, ± rise in Cr, sudden rise in proteinuria
- chronic: PE (typical first presenting symptom), increasing proteinuria and/or tubule dysfunction

Investigations
- renal venography (gold standard), CT or MR angiography, duplex Doppler U/S

Treatment
- thrombolytic therapy ± percutaneous thrombectomy for acute renal vein thrombosis
- anticoagulation with heparin then warfarin (1 yr or indefinitely, depending on risk factors)

SMALL VESSEL DISEASE

1. HYPERTENSIVE NEPHROSCLEROSIS
- see Hypertension, NP31

2. ATEROEMBOLIC RENAL DISEASE
- progressive renal insufficiency due to embolic obstruction of small- and medium-sized renal vessels by atheromatous emboli
- spontaneous or after renal artery manipulation (surgery, angiography, percutaneous angioplasty)
- anticoagulants and thrombolytics interfere with ulcerated plaque healing and can worsen disease
- investigations
  - eosinophilia, eosinophiluria, and hypocomplementia
  - renal biopsy: needle-shaped cholesterol clefts (due to tissue-processing artifacts) with surrounding tissue reaction in small-/medium-sized vessels
- treatment
  - no effective treatment; avoid angiographic and surgical procedures in patients with diffuse atherosclerosis, medical therapy for concomitant cardiovascular disease
- prognosis: poor overall, at least a third will develop ESRD

Stenting and Medical Therapy for Atherosclerotic Renal Artery Stenosis

NEJM 2014;370:13-22
Study: Multicenter, unblinded RCT, median follow-up of 43 ms.
Patients: 947 patients with atherosclerotic renal-artery stenosis who also have significant systolic HTN or CKD.
Intervention: Percutaneous revascularization (stenting) with medical therapy (statins, ARB, calcium channel blockers, HCTZ and BP control) vs. medical therapy alone.
Outcomes: Occurrence of adverse CV or renal event (composite of death from CV or renal cause, MI, stroke, hospitalization for CHF, progressive renal insufficiency, or need for renal replacement therapy) and all-cause mortality.
Results: No significant difference in primary composite end point between participants who received stenting or those on medical therapy alone. No significant differences between the treatment groups in the rates of the individual components of the primary end point or in all-cause mortality.
Conclusion: Renal artery stenting did not confer a significant benefit with respect to the prevention of clinical events when added to comprehensive, multifactorial medical therapy in people with atherosclerotic renal artery stenosis and HTN or CKD.
3. THROMBOTIC MICROANGIOPATHY
- etiologies include the spectrum of TTP-HUS, DIC, severe preeclampsia
- renal involvement more common in HUS than TTP
- renal involvement characterized by fibrin thrombi in glomerular capillary loops ± arterioles
- treatment
  - depends on cause
  - supportive therapy
  - TTP-HUS: plasma exchange, corticosteroids (splenectomy and rituximab if refractory)
- avoid platelet transfusions and ASA

4. CALCINEURIN INHIBITOR NEPHROPATHY
- cyclosporine and tacrolimus
- causes both acute reversible and chronic, largely irreversible nephrotoxicity
- major cause of kidney failure in other solid organ transplants (e.g. heart)
- acute: due to afferent and efferent glomerular capillary constriction leading to decreased GFR (tubular vacuolization)
  - prerenal azotemia
  - treatment: calcium channel blockers or prostaglandin analogs, reduce dose of cyclosporine or switch to another immunosuppressive drug
- chronic: result of obliterative arteriolopathy causing interstitial nephritis and CKD (striped fibrosis), less frequent now due to lower doses of calcineurin inhibitors

Glomerular Diseases

HISTOLOGICAL TERMS OF GLOMERULAR CHANGES

Extent of Changes
- terms used to describe histologically the number of glomeruli affected in a given condition
  - diffuse: majority of glomeruli abnormal
  - focal: some glomeruli affected
- terms used to describe histologically the extent to which individual glomeruli are affected in a given condition
  - global: entire glomerulus abnormal
  - segmental: only part of the glomerulus abnormal

Types of Changes
- proliferation: hyperplasia of one of the glomerular cell types (mesangial, endothelial, parietal epithelial), with or without inflammatory cell infiltration
- membranous changes: capillary wall thickening due to immune deposits or alterations in basement membrane
- crescent formation: parietal epithelial cell proliferation and mononuclear cell infiltration form crescent-shape in Bowman’s space

CLINICAL PRESENTATION OF GLOMERULAR DISEASE

Important Points to Remember
- glomerular diseases have diverse clinical presentations including hematuria, proteinuria, HTN, edema, and decreased GFR
  - each glomerulopathy presents as one of four major glomerular syndromes (these are NOT diagnoses)
    - asymptomatic urinary abnormalities
      - proteinuria
      - hematuria
    - nephritic syndrome
      - acute GN
      - rapidly progressive GN
    - nephrotic syndrome
    - ESRD
- glomerulopathies can be caused by a primary disease or can occur secondary to a systemic disease
- some glomerulopathies can present as more than one syndrome at different times

The Nephritic-Nephrotic Spectrum
- glomerular pathology can present with a clinical picture anywhere on a spectrum with pure nephritic and pure nephrotic syndromes at the extremes
**PROTEINURIA**

- hallmark of nephrotic syndromes
- 24 h urine protein: gold standard to assess degree of proteinuria
  - microalbuminuria
    - defined as ACR ≥25 mg/g (female) or ACR ≥18 mg/g (male)
    - marker of vascular endothelial function
    - an important prognostic marker for kidney disease in DM and HTN (see Diabetes, NP28)
  - an elevated ACR ≥18 or 25 mg/g is the earliest sign of diabetic nephropathy
- composition of normal total urine protein
  - upper limit of normal daily excretion of total protein is 150 mg/d
  - upper limit of normal daily excretion of albumin is 30 mg/d
  - the other normally excreted proteins are either filtered low molecular weight proteins (such as immunoglobulin light chains or β-2 microglobulin) or proteins secreted by the tubular epithelial cells (e.g. Tamm-Horsfall mucoprotein)

**Pathologic Proteinuria**

- Tubulointerstitial
  - Normally low molecular weight proteins (<60 kDa) pass through glomerular filtration barrier and are reabsorbed in proximal tubule
  - Proximal tubule dysfunction causes impaired reabsorption and increased excretion of low molecular weight proteins
  - Albumin (>60 kDa) is not affected; thus, edema is partly secondary to salt and water retention

- Glomerular
  - Normally, the filtration barrier is selectively permeable to size (<60 kDa) and charge (repels negative particles); thus, albumin is filtered to a very limited extent through a normal glomerulus
  - Damage to any component of the glomerular filtration barrier results in loss of albumin and other high molecular weight proteins; thus, edema is secondary to hypoalbuminemia (low oncotic pressure), but also due to enhanced renal tubular reabsorption of filtered sodium and water (possibly due to filtered proteins stimulating the action of cortical collecting duct epithelial sodium channel)

- Overflow
  - Increased production of low molecular weight proteins which exceeds the reabsorptive capacity of the proximal tubule
  - Plasma cell dyscrasias: produce light chain Ig (multiple myeloma, Waldenstrom’s macroglobulinemia, monoclonal gammopathy of undetermined significance)

**Table 9. Daily Excretion of Protein**

<table>
<thead>
<tr>
<th>Daily Excretion</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;150 mg total protein (and &lt;30 mg albumin)</td>
<td>Normal</td>
</tr>
<tr>
<td>30-300 mg albumin</td>
<td>Microalbuminuria</td>
</tr>
<tr>
<td>&gt;3500 mg total protein/1.73m² BSA</td>
<td>Nephrotic range proteinuria</td>
</tr>
<tr>
<td>Variable amount of proteinuria</td>
<td>Can be seen with glomerular disease; e.g. mild glomerular disease can lead to a mild degree of proteinuria, proliferative lesions may also be associated with some degree of proteinuria</td>
</tr>
<tr>
<td>Up to 2,000 mg per d</td>
<td>Possible tubular disease because of failure to reabsorb filtered proteins</td>
</tr>
</tbody>
</table>
Investigations
• urine R&M, C&S, urea, Cr
• further workup (if degree of proteinuria >0.5 g/d, casts, and/or hematuria)
  ▪ CBC, glucose, electrolytes, 24 h urine protein, and Cr
  ▪ urine and serum immunoelectrophoresis, abdominal/pelvic U/S
  ▪ serology: ANA, RF, p-ANCA (MPO), c-ANCA (PR3), Hep B, Hep C, HIV, ASOT
• indications for nephrology referral
  ▪ generally, if there is "heavy" (ACR >265 mg/g) proteinuria, should refer to nephrologist
  ▪ definitely if there is nephrotic syndrome: marked proteinuria >3.5 g/1.73m2/d with
    hypoalbuminemia (<35 g/L)

HEMATURIA
• hallmark of nephritic syndromes
• presence of blood or RBCs in urine
  ▪ gross hematuria: pink, red, or tea-colored urine
    • in gross hematuria, the urine should be centrifuged:
      ▪ if the sediment is red, true hematuria
      ▪ if the supernatant is red, test for heme with a dipstick
        • if supernatant positive for heme: myoglobinuria or hemoglobinuria
        • if negative for heme: pseudohematuria; consider medications (e.g. rifampin), food
dlies (e.g. beets), or metabolites (e.g. porphyria)
• microscopic hematuria: normal colored urine, >2-3 RBCs/HPF on microscopy

Figure 13. Approach to red urine

Investigations for Hematuria
• Hx and P/E: family history of nephrolithiasis, hearing loss (Alport’s), cerebral aneurysm
  (PCKD), diet, recent URTI, irritative and obstructive urinary symptoms (UTI)
• urine R&M, C&S, urea, Cr
• renal U/S
• 24 h urine stone workup if there is a history of stone formation or if there is a stone noted on
  imaging: calcium, oxalate, citrate, magnesium, uric acid, cystine
• further workup (if casts and/or proteinuria): CBC, electrolytes, 24 h urine protein and Cr,
  serology (ANA, RF, C3, C4, p-ANCA, c-ANCA, ASOT)
• consider urology consult and possible cystoscopy if not clearly a nephrologic source for
  hematuria or if >50 yr of age
Glomerular Syndromes

1. ASYMPTOMATIC URINARY ABNORMALITIES

Clinical/Lab Features
- proteinuria (usually <2 g/d) and/or microscopic or macroscopic hematuria
  - isolated proteinuria
    - can be postural
    - occasionally can signal beginning of more serious GN (e.g. FSGS, IgA nephropathy, amyloid, diabetic nephropathy)
- hematuria with or without proteinuria
  - IgA nephropathy (Berger’s disease): most common type of primary glomerular disease worldwide, usually presents after viral URTI
  - hereditary nephritis (Alport’s disease): X-linked nephritis often associated with sensorineural hearing loss; proteinuria <2 g/d
  - thin basement membrane disease: usually autosomal dominant, without proteinuria; benign
  - benign recurrent hematuria: hematuria associated with febrile illness, exercise, or immunization; a diagnosis of exclusion after other possibilities are ruled out

2. NEPHRITIC SYNDROME

ACUTE NEPHRITIC SYNDROME
- a subset of nephritic syndrome in which the clinical course proceeds over days

Etiology
- etiology can be divided into low and normal complement levels (see Figure 14)
- frequently immune-mediated, with Ig and C3 deposits found in GBM
- outcome dependent on etiology

Clinical/Lab Features
- proteinuria (but <3.5 g/1.73 m²/d), abrupt onset hematuria (microscopic or macroscopic, azotemia (increased Cr and urea), RBC casts and/or dysmorphic RBCs in urine, oliguria, HTN (due to salt and water retention), peripheral edema/puffy eyes, smoky urine

Figure 14. Approach to nephritic syndrome

RAPIDLY PROGRESSIVE GLOMERULONEPHRITIS/CRESCENTIC GLOMERULONEPHRITIS
- a subset of nephritic syndrome in which the clinical course proceeds over weeks to months
- clinical diagnosis, not histopathological
- any cause of GN can present as RPGN (except minimal change disease)
- additional etiologies seen only as RPGN: Goodpasture’s syndrome and granulomatosis with polyangiitis (previously called Wegener’s granulomatosis)
Clinical/Lab Features
- fibrous crescents typically present on renal histopathology
- RBC casts and/or dysmorphic RBCs in urine
- classified by immunofluorescence staining
- Type I: Anti-GBM mediated (15% of cases)
- Type II: Immune Complex Mediated (24% of cases)
- Type III: Non-Immune Mediated (60% of cases)
- Type IV: Double Antibody Positive
- treatment: underlying cause for postinfectious; corticosteroids + cyclophosphamide or other cytotoxic agent + plasmaphoresis in select cases
- prognosis: 50% recovery with early treatment, depends on underlying cause

3. NEPHROTIC SYNDROME

Clinical/Lab Features
- heavy proteinuria (>3.5 g/1.73m²/d)
- hypoalbuminemia
- edema
- hyperlipidemia (elevated LDL cholesterol), lipiduria (fatty casts and oval fat bodies on microscopy)
- hypercoagulable state (due to antithrombin III, Protein C, and Protein S urinary losses)
- patient may report frothy urine
- glomerular pathology on renal biopsy
  - minimal change disease (or minimal lesion disease or nil disease) – e.g. glomeruli appear normal on light microscopy
  - membranous glomerulopathy
  - focal segmental glomerulosclerosis (FSGS)
  - membranoproliferative GN
  - nodular glomerulosclerosis
- each can be idiopathic or secondary to a systemic disease or drug (sirolimus can cause proteinuria without obvious glomerular pathology)

Table 10. Nephrotic Syndrome

4. END STAGE RENAL DISEASE
- refer to section End Stage Renal Disease, NP35

INVESTIGATIONS FOR GLOMERULAR DISEASE
- blood work
  - first presentation: electrolytes, Cr, urea, albumin, fasting lipids
  - determining etiology: CBC, ESR, serum immunoelectrophoresis, anti-GBM, C3, C4, ANA, p-ANCA, c-ANCA, cryoglobulins, HBV and HCV serology, ASOT (anti-streptolysin titres), VDRL, HIV
- urinalysis: RBCs, WBCs, casts, protein
- 24 h urine for protein and CrCl
- radiology
  - CXR (infiltrates, CHF, pleural effusion)
  - renal U/S
  - renal biopsy (percutaneous or open) if heavy proteinuria or renal insufficiency and cause is not obviously diabetic nephropathy
- urine immunoelectrophoresis
  - for Bence-Jones protein if proteinuria present

SECONDARY CAUSES OF GLOMERULAR DISEASE

Amyloidosis
- nodular deposits of amyloid in mesangium, usually related to amyloid light chain (AL)
- presents as nephrotic range proteinuria with progressive renal insufficiency
- can be primary or secondary
- secondary causes: multiple myeloma, TB, rheumatoid arthritis, malignancy
Systemic Lupus Erythematosus
- lupus nephritis can present as any of the glomerular syndromes
- nephrotic syndrome with an active sediment is most common presentation
- GN caused by immune complex deposition in capillary loops and mesangium with resulting renal injury
- serum complement levels are usually low during periods of active renal disease
- children and males with SLE are more likely to develop nephritis

Henoch-Schönlein Purpura
- seen more commonly in children
- purpura on buttocks and legs, abdominal pain, arthralgia, and fever
- glomeruli show varying degrees of mesangial hypercellularity
- IgA and C3 staining of mesangium
- usually benign, self-limiting course, 10% progress to CKD

Goodpasture’s Disease
- antibodies against type IV collagen present in lungs and GBM
- more common in 3rd and 6th decades of life, males slightly more affected than females
- present with RPGN type I and hemoptysis/dyspnea
- pulmonary hemorrhage more common in smokers and males
- treat with plasma exchange, cyclophosphamide, prednisone

ANCA-Associated Vasculitis (e.g. Granulomatosis with Polyangiitis and Microscopic Polyangiitis [formerly Wegener’s Granulomatosis])
- PR3-ANCA (c-ANCA) most commonly associated with the clinical picture of granulomatosis with polyangiitis (previously called Wegener’s granulomatosis)
- MPO-ANCA (p-ANCA) most commonly associated with the clinical picture of microscopic polyangiitis
- renal involvement very common
- focal segmental necrotizing RPGN with no immune staining
- may be indolent or fulminant in progression
- vasculitis and granulomas rarely seen on renal biopsy
- treating typically involves cyclophosphamide and prednisone

Cryoglobulinemia
- cryoglobulins: monoclonal IgM and polyclonal IgG
- presents as purpura, fever, Raynaud’s phenomenon, and arthralgias
- at least 50% of patients have hepatitis C
- renal disease seen in 40% of patients (isolated proteinuria/hematuria progressing to nephritic syndrome)
- most patients have decreased serum complement (C4 initially)
- treat hepatitis C, plasmapheresis
- overall prognosis: 75% renal recovery

Shunt Nephritis
- immune-complex mediated nephritis associated with chronically infected ventriculoatrial shunts inserted for treatment of hydrocephalus
- presents as acute nephritic syndrome with decreased serum complement
- nephrotic range proteinuria in 25% of patients
HIV-Associated Renal Disease
1. direct nephrotoxic effect of HIV infection, antiretroviral drugs (e.g. tenofovir, indinavir), and other drugs used to treat HIV-associated infections
2. HIV-associated nephropathy
   - histology: focal and segmental glomerular collapse with mesangial sclerosis; “collapsing FSGS”
   - tubular cystic dilation and tubulo-reticular inclusions
   - clinical features: predominant in African American men, heavy proteinuria, progressive renal insufficiency
   - prognosis: kidney failure within 1 yr without treatment
   - therapy: short-term, high dose steroids, ACEI, HAART

Infective Endocarditis
• manifests as mild form of acute nephritic syndrome with decreased serum complement
• S. aureus is most common infecting agent
• treatment with appropriate antibiotics usually resolves GN

Hepatitis B
• can result in membranous nephropathy, polyarteritis nodosa, membranoproliferative GN

Hepatitis C
• can result in membranoproliferative GN, cryoglobulinemia, and membranous nephropathy

Syphilis
• can result in membranous GN

Tubulointerstitial Disease

TUBULOINTERSTITIAL NEPHRITIS

Definition
• cellular infiltrates affecting primarily the renal interstitium and tubular cells
• functional tubule defects are disproportionately greater than the decrease in GFR
• classified as acute or chronic

Signs and Symptoms
• manifestation of disease depends on site of tubule affected
  1. proximal tubule (e.g. multiple myeloma, heavy metals)
     • Fanconi syndrome: decreased reabsorption in proximal tubule causing glycosuria, aminoaciduria, phosphaturia, hypouricemia
     • proximal RTA (decreased bicarbonate absorption): Type II RTA
  2. distal tubule (e.g. amyloidosis, obstruction)
     • distal RTA (Type I RTA), usually hypokalemic
     • Na+ -wasting nephropathy
     • ± hyperkalemia leading to type IV RTA (where reduced renal bicarbonate production is caused by hyperkalemia)
  3. collecting duct (e.g. sickle cell anemia, analgesics, PCKD)
     • urinary concentrating defect leading to mild nephrogenic DI
     • polyuria

1. ACUTE TUBULOINTERSTITIAL NEPHRITIS

Definition
• rapid (days to weeks) decline in renal function
• 10-20% of all AKI

Etiology
• hypersensitivity
  1. antibiotics: β-lactams, sulfonamides, rifampin, quinolones, cephalosporins
  2. other: NSAIDs, allopurinol, furosemide, thiazides, triamterene, PPIs, acyclovir, phenytoin, cimetidine
• infections
  • bacterial pyelonephritis, Streptococcus, brucellosis, Legionella, CMV, EBV, toxoplasmosis, leptospirosis
• immune
  • SLE, acute allograft rejection, Sjögren's syndrome, sarcoidosis, mixed essential cryoglobulinemia
• idiopathic

Pathophysiology
• acute inflammatory cell infiltrates into renal interstitium
Signs and Symptoms

- AKI
- if hypersensitivity reaction: may see fever, skin rash, arthralgia, serum sickness-like syndrome (particularly rifampin)
- if pyelonephritis: flank pain and costovertebral angle (CVA) tenderness
- other signs and symptoms based on underlying etiology
- HTN and edema are uncommon

Investigations

- mild, non-nephrotic range proteinuria and microscopic hematuria
- urine
  - sterile pyuria, WBC casts, mild proteinuria, hematuria
  - eosinophils if AIN
- blood work
  - increased Cr and urea
  - eosinophilia if drug reaction
  - normal AG metabolic acidosis (RTA)
  - hypophosphatemia, hyperkalemia, hyponatremia
- gallium scan often shows intense signal due to inflammatory infiltrate
- renal biopsy definitive

Treatment

- treat underlying cause (e.g. stop offending medications, antibiotics if pyelonephritis)
- corticosteroids (may be indicated in allergic or immune disease)

Prognosis

- recovery within 2 wk if underlying insult can be eliminated
- the longer the patient is in renal failure, the less likely full renal recovery becomes

2. CHRONIC TUBULOINTERSTITIAL NEPHRITIS

Definition

- characterized by slowly progressive renal failure, moderate proteinuria, and signs of abnormal tubule function

Etiology

- persistence or progression of acute TIN
- urinary tract obstruction: most important cause of chronic TIN (tumors, stones, bladder outlet obstruction, vesicoureteral reflux)
- chronic pyelonephritis due to vesicoureteral reflux or UTI with obstruction
- nephrotoxins
  - exogenous
    - analgesics: NSAIDs (common), acetaminophen
    - cisplatin, lithium, cyclosporine, tacrolimus
    - heavy metals (lead, cadmium, copper, lithium, mercury, arsenic)
    - radiation
    - Chinese herbs
  - endogenous
    - hypercalcemia, hypokalemia, oxalate, uric acid nephropathy
- vascular disease: ischemic nephrosclerosis, atheroembolic disease
- malignancies: multiple myeloma, lymphoma
- granulomatous: TB, sarcoidosis, granulomatosis with polyangiitis
- immune: SLE, SJögren’s, cryoglobulinemia, Goodpasture’s, amyloidosis, renal graft rejection, vasculitis
- hereditary: cystic diseases of the kidney, sickle cell disease
- others: radiation, Balkan (endemic) nephropathy

Pathophysiology

- fibrosis of interstitium with atrophy of tubules, mononuclear cell inflammation

Signs and Symptoms

- tubular dysfunction (e.g. acidosis, electrolyte disturbances)
- progressive renal failure with azotemia and uremia
- dependent on underlying etiology

Treatment

- stop offending agent or treat underlying disease
- supportive measures: correct metabolic disorders ($\text{Ca}^{2+}$, $\text{PO}_4^{3-}$) and anemia
Findings which Suggest Chronic Tubulointerstitial Nephritis
- normal AG metabolic acidosis
- hyperkalemia (out of proportion to degree of renal insufficiency)
- polyuria, nocturia
- partial or complete Fanconi’s syndrome
- urine: mild proteinuria, few RBCs and WBCs, no RBC casts
- U/S: shrunken kidneys with irregular contours

3. ACUTE TUBULAR NECROSIS

Definition
- abrupt and sustained decline in GFR within minutes to days after ischemic/nephrotoxic insult
- GFR reduced (this serves the purpose of avoiding life-threatening urinary loss of fluid and electrolytes from non-functioning tubules)

Etiology

- Toxins
  - Exogenous
    - Antibiotics
      - Aminoglycosides
      - Cephalosporins
      - Amphotericin B
    - Antiviral (cidofovir)
    - Antineoplastics
      - Cisplatin
      - Methotrexate
    - Contrast media
    - Heavy metals
    - Other
      - Fluorinated anesthetic
      - Ethylene glycol
  - Endogenous
    - Endotoxins (bacterial)
    - Myoglobin
    - Hemoglobin
  - Decreased Circulating Volume
    - Hemorrhage including post-surgical
    - Skin losses
    - GI losses
    - Renal losses
  - Decreased Effective Circulating Volume
    - Heart failure
    - Liver failure
    - Sepsis
    - Anaphylaxis
  - Vessel Occlusion
    - Large or small renal artery involvement

Clinical Presentation
- typically presents as an abrupt rise in urea and Cr after a hypotensive episode, sepsis, rhabdomyolysis, or administration of nephrotoxic drug
- urine: high FE Na+, pigmented-granular casts

Complications
- hyperkalemia: can occur rapidly and cause serious arrhythmias
- metabolic acidosis, decreased Ca²⁺, increased PO₄³⁻, hypoalbuminemia

Investigations
- blood work: CBC, electrolytes, Cr, urea, Ca²⁺, PO₄³⁻, blood gases
- urine: R&M, electrolytes, osmolality, microscopic urinalysis searching for pigmented granular casts
- ECG
- abdominal U/S
- rule out other causes of prerenal/postrenal azotemia and intrinsic AKI (GN, AIN, vasculitis)

Therapy
- largely supportive once underlying problem is corrected
- loop diuretics may help manage volume overload and reduce tubular metabolic requirements to allow for recovery (controversial)
- consider early dialysis in severe/rapidly progressing cases to prevent uremic syndrome

Prevention
- correct fluid balance before surgical procedures
- for patients with chronic renal disease requiring radiographic contrast
  - give N-acetylcysteine 600-1200 mg PO bid day before and day of procedure, give intravenous isotonic fluid (either NaCl or NaHCO₃)
  - isotonic NaHCO₃ at 3 mL/kg over 1 h before procedure and 1 mL/kg/h for 6 h post-procedure if not contraindicated
- avoid giving diuretics, ACEI, cyclosporine on morning of procedure if possible
- use renal-adjusted doses of nephrotoxic drugs in patients with renal insufficiency
Analgesic Nephropathies

1. Vasomotor AKI
   - normally prostaglandins vasodilate afferent renal arteriole to maintain blood flow
   - NSAI
dors act by blocking cyclooxygenase enzyme, thereby preventing prostaglandin synthesis and causing renal ischemia
   - more common in elderly, underlying renal disease, hypovolemia (diuretics, CHF, cirrhosis, nephrotic syndrome)
   - clinically: develop prerenal azotemia within a few days of starting NSAID
   - treatment: discontinue NSAID, dialysis rarely needed

2. Acute Interstitial Nephritis
   - fenoprofen (60%), ibuprofen, naproxen
   - may be associated with minimal change glomerulopathy and nephrotic range proteinuria
   - resolves eventually with discontinuation of NSAID, may require interval dialysis
   - short-term high dose steroids (1 mg/kg/d of prednisone) may hasten recovery

3. Chronic Interstitial Nephritis
   - due to excessive consumption of antipyretics (phenacetin or acetaminophen) in combination with NSAI
dors
   - seen in patients who also have emotional stress, psychiatric symptoms, and GI disturbance
   - papillary necrosis
     - gross hematuria, flank pain, declining renal function
     - calyceal filling defect seen with IVP – “ring sign”
   - increased risk of transitional cell carcinoma of renal pelvis
   - good prognosis if discontinue analgesics

4. Acute Tubular Necrosis
   - can be caused by acetaminophen
     - incidence of renal dysfunction is related to the severity of acetaminophen ingestion
     - vascular endothelial damage can also occur
     - both direct toxicity and ischemia contribute to the tubular damage
     - renal function spontaneously returns to baseline within 1-4 wk
     - dialysis may be required during the acute episode of ingestion

5. Other Effects of NSAI
dors
   - sodium retention (2º to reduced GFR)
   - hyperkalemia, HTN (2º to hyporeninemic hypoaldosteronism)
   - excess water retention (due to elimination of ADH – antagonistic effect of prostaglandins)

Systemic Disease with Renal Manifestation

Diabetes
   - diabetic nephropathy: presence of microalbuminuria or overt nephropathy (e.g. macroalbuminuria) in patients with DM who lack indicators of other renal diseases
   - most common cause of end-stage renal failure in North America
   - 35-50% of patients with type 1 DM will develop nephropathy, unknown percentage of type 2
   - at diagnosis up to 30% of patients with type 2 DM have albuminuria (75% microalbuminuria, 25% overt nephropathy)
   - microalbuminuria is a risk factor for progression to overt nephropathy and cardiovascular disease
   - once macroalbuminuria is established, renal function declines, 50% patients reach ESRD within 7-10 yr
   - associated with HTN and diabetic retinopathy (especially type 1 DM) and/or neuropathy (especially type 2 DM)
   - indication of possible non-diabetic cause of renal disease in patients with DM:
     - rising Cr with little/no proteinuria
     - lack of retinopathy or neuropathy (microvascular complications)
     - persistent hematuria (microscopic or macroscopic)
     - signs or symptoms of systemic disease
     - inappropriate time course; rapidly rising Cr, renal disease in a patient with short duration of DM
     - family history of non-diabetic renal disease (e.g. PCKD, Alport’s)

DM is one of the causes of ESRD that does not result in small kidneys at presentation of ESRD. The others are amyloidosis, HIV nephropathy, PCKD, and multiple myeloma

ACEI can cause hyperkalemia. Therefore, be sure to watch serum K⁺, especially if patient has DM and renal insufficiency
**DIABETIC RENAL COMPLICATIONS**

1. **Progressive Glomerulosclerosis**
   - classic diabetic glomerular lesion: Kimmelstiel-Wilson nodular glomerulosclerosis (15-20%)
   - more common lesion is diffuse glomerulosclerosis with a uniform increase in mesangial matrix

<table>
<thead>
<tr>

</tbody>
</table>

2. **Accelerated Atherosclerosis**
   - common finding
   - decreased GFR
   - may increase angiotensin II production resulting in increased BP
   - increased risk of ATN secondary to contrast media

3. **Autonomic Neuropathy**
   - affects bladder leading to functional obstruction and urinary retention
   - residual urine promotes infection
   - obstructive nephropathy

4. **Papillary Necrosis**
   - type 1 DM susceptible to ischemic necrosis of medullary papillae
   - sloughed papillae may obstruct ureter
   - can present as renal colic or with obstructive features ± hydronephrosis

2013 Canadian Diabetes Association Clinical Practice Guidelines on Chronic Kidney Disease in Diabetics

- screen for microalbuminuria with a random urine test for albumin to Cr ratio (ACR) and eGFR with a serum Cr (e.g. using MDRD equation)
  - type 1 DM: annually in post-pubertal individuals after 5 yr of diagnosis
  - type 2 DM: at diagnosis, then annually
  - If eGFR >60 mL/min or ACR <2.0 mg/mEq; no CKD, re-screen in 1 yr
  - If urine ACR >20.0 mg/mEq; diagnose CKD
  - If ACR <0.2 mg/mEq/ml but >2.0 mg/mEq/ml: order serum Cr for eGFR in 3 mo and 2 repeats of random urine ACRs over the next 3 mo; if eGFR >60 mL/min or if >2/3 ACRs are >2.0 mg/mEq/ml, diagnose CKD
  - if CKD diagnosed, ordered urine R-M and dipstick, if negative then diagnose CKD in DM
  - with CKD in DM: urine ACR and serum Cr (for eGFR) every 6 mo
  - delay screening if transient cause of albuminuria or low eGFR
  - evaluate for other causes of proteinuria, rule out non-diabetic renal disease
  - avoid unnecessary potential nephrotoxins (NSAIDs, aminoglycosides, dye studies)

Priorities in the Management of Patients with DM

1. vascular protection for all patients with DM
   - ACEI, antplatelet therapy (as indicated)
   - BP control, glycemic control, lifestyle modification, lipid control
2. optimization of BP in patients who are hypertensive
   - treat according to HTN guidelines
3. renal protection for DM patients with nephropathy (even in absence of HTN)
   - type 1 DM; ACEI
   - type 2 DM: CrCl >60 mL/min; ACEI or ARB – CrCl <60 mL/min; ARB
   - 2nd line agents: nondihydropyridine calcium channel blockers (diltiazem, verapamil)
   - ACEI and ARB can be safely used together if needed for control of significant proteinuria (monitor for hyperkalemia and acute rise in Cr)
   - check serum Cr and K⁺ levels within 1 wk of initiating ACEI or ARB and at time of acute illness
   - serum Cr can safely be allowed to rise up to 30% with initiation of ACEI or ARB, usually stabilizes after 2-4 wk, monitor for significant worsening of renal function or hyperkalemia
   - if >30% rise in serum Cr or hyperkalemia, discontinue medication and consider 2nd line agent
   - consider holding ACEI, ARB, and/or diuretic with acute illness and in women before becoming pregnant
   - consider referral to nephrologist if ACR >60 mg/mEq, eGFR <30 mL/min, progressive kidney function loss, unable to achieve BP targets, or unable to stay on ACEI or ARB

Figure 17. GFR and urine protein over time in DM

Renoprotective Effect of Angiotensin-Receptor Antagonist (IRMA) in People with Nephropathy Due to Type 2 DM

Study: Multicenter, RCT, mean follow-up of 2.6 yr.

Patients: 806 patients (mean age 70 yr) with type 2 DM, HTN, and nephropathy (24 h-proteinuria >900 mg, serum Cr 88-285 μmol/L [male], serum Cr 106-285 μmol/L [female]).

Intervention: BP control with irbesartan vs. amldipine or placebo, with use of adjuncts (not including ACEI, ARB, or CCB) as needed.

Outcome: Primary composite endpoint included doubling of serum Cr, ESRD, or death. Secondary composite endpoint included mortality and mortality from CVD causes.

Results: BP control was similar in all three arms. Irbesartan had a relative risk reduction of 20% vs. placebo and 23% vs. amldipine for the primary endpoint. The irbesartan group had a 33% risk reduction vs. placebo and 37% risk reduction vs. amldipine for risk of doubling serum Cr. Serum Cr increased more slowly in the irbesartan group vs. placebo or amldipine. No difference in absolute mortality or secondary end point.

Conclusion: Irbesartan conferred significant renoprotective benefits in patients with type 2 DM and nephropathy, independent of blood pressure lowering effects.

Renal Outcomes with Telmisartan, Ramipril, or Both in People at High Vascular Risk (ONTARGET Study)

Lancet 2008;372:547-553

Study: Prospective, multicenter, double-blind, RCT.

Participants: 35,820 patients with median follow-up of 56 mo.

Intervention: Patients received either ramipril (10 mg/d; n=8,576), telmisartan (80 mg/d; n=8,542), or a combination of both drugs (10 mg/d; n=8,502).

Primary Outcome: Composite of dialysis, doubling of creatinine level, and death.

Results: The number of outcome events was similar for telmisartan (n=1,147) and ramipril (1,150; HR 1.00, 95% CI 0.92-1.09), but was increased with combination therapy (1,232; HR 1.24, 1.01-1.51, p=0.038). The need for dialysis or doubling of serum creatinine, was similar with telmisartan (1,097) and ramipril (1,174; HR 1.09, 0.99-1.34) and more frequent with combination therapy (2,122; HR 1.24, 1.01-1.51, p=0.038). Estimated GFR declined least with ramipril compared with telmisartan or combination therapy (p<0.001). The increase in urinary albumin excretion was less with telmisartan (n=1,233; HR 1.34) and more frequent with combination therapy (1,233; HR 1.00, 95% CI 0.92-1.09), but was similar for telmisartan (n=1,147) and ramipril.

Results:

Primary composite endpoint included doubling of serum Cr, ESRD, or death. Secondary composite endpoint included mortality and mortality from CVD causes.

Conclusion: Renal outcomes were similar in both telmisartan and ramipril monotherapy. Combination therapy reduced proteinuria to a greater extent than monotherapy, but was associated with poorer renal outcomes.
Scleroderma

- 50% of scleroderma patients have renal involvement (mild proteinuria, high Cr, HTN)
- histology: media thickened, "onion skin" hypertrophy of small renal arteries, fibrinoid necrosis of afferent arterioles and glomeruli
- 10-15% scleroderma patients have a "scleroderma renal crisis" (occurs in first few years of disease): malignant HTN, ARF, microangiopathy, volume overload, visual changes, HTN encephalopathy
- renal involvement usually occurs early in the course of illness
- treatment: BP control with ACEI slows progression of renal disease

Multiple Myeloma

- see Hematology; H49
- malignant proliferation of plasma cells in the bone marrow with the production of immunoglobulins
- patients may present with severe bone disease and renal failure
- light chains are filtered at the glomerulus and appear as Bence-Jones proteins in the urine (monoclonal light chains)
- kidney damage can occur by several mechanisms
  - hypercalcemia
  - light chain cast nephropathy (LCCN, see below) or "myeloma kidney"
  - hyperuricemia
  - infection
  - secondary amyloidosis
  - monoclonal Ig deposition disease (MIDD)
  - diffuse tubular obstruction
- LCCN
  - large tubular casts in urine sediment (light chains + Tamm-Horsfall protein)
- proteinuria and renal insufficiency, can progress rapidly to kidney failure
- MIDD
  - deposits of monoclonal Ig in kidney, liver, heart, and other organs
  - mostly light chains (85-90%)
- causes nodular glomerulosclerosis (similar to diabetic nephropathy)
- lab features: increased BUN, increased Cr, urine protein immunoelectrophoresis positive for Bence-Jones protein (not detected on urine dipstick)
- poor candidates for kidney transplantation

Malignancy

- cancer can have many different renal manifestations
- kidney transplantation cannot be performed unless malignancy is cured
  - solid tumors: mild proteinuria or membranous GN
  - lymphoma: minimal change GN (Hodgkin’s) or membranous GN (non-Hodgkin’s)
  - renal cell carcinoma
  - tumor lysis syndrome: hyperuricemia, diffuse tubular obstruction
  - chemotherapy (especially cisplatin): ATN or chronic TIN
  - pelvic tumors/mets: postrenal failure secondary to obstruction
  - 2’ amyloidosis
  - radiotherapy (radiation nephritis)

Hypertension

- HTN occurs in about 20% of population
- etiology classified as primary ("essential"); makes up 90% of cases) or secondary
- primary HTN can cause kidney disease (hypertensive nephrosclerosis), which may in turn exacerbate the HTN
- secondary HTN can be caused by renal parenchymal or renal vascular disease

**Hypertensive Nephrosclerosis**

**Table 12. Chronic vs. Malignant Nephrosclerosis**

**Renovascular Hypertension**

- see Vascular Diseases of the Kidney, NP17

**Renal Parenchymal Hypertension**

- HTN secondary to GN, AIN, diabetic nephropathy, or any other chronic renal disease
- mechanism of HTN not fully understood but may include
  - excess RAAS activation due to inflammation and fibrosis in multiple small intra-renal vessels
  - production of unknown vasopressors, lack of production of unknown vasodilators, or lack of clearance of endogenous vasopressor
  - ineffective sodium excretion with fluid overload

**Investigations**

- as well as investigations for renovascular HTN, additional tests may include
  - 24 h urinary estimations of Cr clearance and protein excretion
  - imaging (U/S, CT)
  - serology for collagen-vascular disease
  - renal biopsy

**Treatment**

- most chronic renal disease is irreversible, but treatment of HTN can slow the progression of renal insufficiency
- control ECF volume: Na+ restriction (88 mEq/d intake), diuretic, dialysis with end-stage disease
- ACEI or ARB may provide added benefit (monitor K+ and Cr) if there is significant proteinuria (>300 mg/d)

**Cystic Diseases of the Kidney**

- characterized by epithelium-lined cavities filled with fluid or semisolid debris within the kidneys
- includes: simple cysts (present in 50% of population over 50), medullary cystic kidney, medullary sponge kidney, polycystic kidney disease (autosomal dominant and recessive), and acquired cystic kidney disease (in chronic hemodialysis patients)

**Adult Polycystic Kidney Disease**

- autosomal dominant; at least 2 genes: **PKD1** (chr 16p) and **PKD2** (chr 4q)
- **PKD1** (1:400), **PKD2** (1:1,000) accounts for about 10% of cases of renal failure
- patients generally heterozygous for mutant polycystin gene but accumulate a series of second “somatic hits” precipitating the condition
- **PKD1** encodes a protein that is responsible for cell-cell and cell-matrix interaction and sensing fluid flow by associating with cilia
- **PKD2** encodes a protein that is a Ca2+ permeable nonselective cation channel that associates with cilia and is thought to control intracellular Ca2+ in response to flow
- defect leads to abnormal proliferation and apoptosis of tubular epithelial cells leading to cyst growth
- extrarenal manifestations: most common; multiple asymptomatic hepatic cysts (33%), cerebral aneurysm (10%), diverticulosis, and mitral valve prolapse (25%)
- polycystic liver disease rarely causes liver failure
- less common: cysts in pancreas, spleen, thyroid, ovary, seminal vesicles, and aorta

Hypercalcemia complicates many cancers and can cause multiple kinds of renal disorders (renal vasoconstriction with reduced OTR, salt-wasting with volume depletion, risk of calcium kidney stones)
Signs and Symptoms
- often asymptomatic; discovered incidentally on imaging or by screening those with FHx
- acute abdominal flank pain/dull lumbar back pain
- hematuria (microscopic frequently initial sign, gross)
- nocturia (urinary concentrating defect)
- rarely extra-renal presentation (e.g. ruptured berry aneurysm, diverticulitis)
- HTN (increased renin due to focal compression of intrarenal arteries by cysts) (60-75%)
- ± palpable kidneys

Common Complications
- urinary tract and cyst infections, HTN, CRF, nephrolithiasis (5-15%), flank and chronic back pain

Clinical Course
- polycystic changes are always bilateral and can present at any age
- clinical manifestations rare before age 20-25
- kidneys are normal at birth but may enlarge to 10x normal size
- variable progression to renal functional impairment (ESRD in up to 50% by age 60)

Investigations
- radiographic diagnosis: best accomplished by renal U/S (enlarged kidneys, multiple cysts throughout renal parenchyma, increased cortical thickness, splaying of renal calyces)
- CT abdo with contrast (for equivocal cases, occasionally reveals more cystic involvement)
- gene linkage analysis for PKD1 for asymptomatic carriers
- Cr, BUN, urine R&M (to assess for hematuria)

Treatment
- goal: to preserve renal function by prevention and treatment of complications
- educate patient and family about disease, its manifestations, and inheritance pattern
- genetic counseling: transmission rate 50% from affected parent
- prevention and early treatment of urinary tract and cyst infections (avoid instrumentation of GU tract)
- TMP/SMX, ciprofloxacin: able to penetrate cyst walls, achieve therapeutic levels
- adequate hydration to prevent stone formation
- avoid contact sports due to greater risk of injury to enlarged kidneys
- screen for cerebral aneurysms if family history of aneurysmal hemorrhages
- monitor blood pressure and treat HTN with ACEI
- dialysis or transplant for ESRD (disease does not recur in transplanted kidney)
- may require nephrectomy to create room for renal transplant

Medullary Sponge Kidney
- common, autosomal dominant, usually diagnosed in 4th-5th decades
- multiple cystic dilatations in the collecting ducts of the medulla
- renal stones, hematuria, and recurrent UTIs are common features
- an estimated 10% of patients who present with renal stones have medullary sponge kidney
- nephrocalcinosis on abdominal x-ray in 50% patients, often detect asymptomatic patients incidentally
- diagnosis: contrast filled medullary cysts on IVP leading to characteristic radial pattern (“bouquet of flowers”), “Swiss cheese” appearance on histological cross-section
- treat UTIs and stone formation as indicated
- does not result in renal failure

Autosomal Recessive Polycystic Kidney Disease
- 1:20,000 incidence
- prenatal diagnosis by enlarged kidneys
- perinatal death from respiratory failure
- patients who survive perinatal period develop CHF, HTN, CKD
- treated with kidney and/or liver transplant
**Acute Kidney Injury**

**Definition**
- abrupt decline in renal function leading to increased nitrogenous waste products normally excreted by the kidney
- formerly known as Acute Renal Failure

**Clinical Features**
- azotemia (increased BUN, Cr)
- abnormal urine volume: formally <0.5 ml/kg/h for >6 h but can manifest as anuria, oliguria, or polyuria

**Approach to AKI**

**Investigations**
- blood work: CBC, electrolytes, Cr, urea (think prerenal if increase in urea is relatively greater than increase in Cr), Ca²⁺, PO₄³⁻
- urine volume, C&S, R&M: sediment, casts, crystals
- urinary indices: electrolytes, osmolality
- fluid challenge (e.g. fluid bolus to rule out most prerenal causes)
- imaging: abdo U/S (assess kidney size, hydronephrosis, postrenal obstruction)
- indications for renal biopsy
  - diagnosis is not certain
  - prerenal azotemia or ATN is unlikely
  - oliguria persists >4 wk

**Treatment**
1. preliminary measures
   - prerenal
     - correct prerenal factors: optimize volume status and cardiac performance using fluids that will stay in the plasma subcompartment (NS, albumin, blood/plasma), hold ACEI/ARB (gently rehydrate when needed, e.g. CHF)
   - renal
     - address reversible renal causes: discontinue nephrotoxic drugs, treat infection, and optimize electrolytes
   - postrenal
     - consider obstruction: structural (stones, strictures) vs. functional (neuropathy)
     - treat with Foley catheter, indwelling bladder catheter, nephrostomy, stenting
2. treat complications
   - fluid overload
   - NaCl restriction
   - high dose loop diuretics
   - hyperkalemia (refer to Approach to Hyperkalemia, NP12)

**Drugs Implicated in Prerenal Azotemia**
- Diuretics
- NSAIDs
- ACEI/ARBs

**Indications for Dialysis**
(refractory to medical therapy)
- AE IUO
- Acidosis
- Electrolyte imbalance (K⁺)
- Intoxication
- Overload (fluid)
- Uromic encephalopathy, pericarditis, urea >35-50 mM
adjust dosages of medications cleared by kidney (e.g. amiodarone, digoxin, cyclosporin, tacrolimus, some antibiotics, and chemotherapeutic agents)

3. definitive therapy depends on etiology
• note: renal transplant is not a therapy for AKI

**Prognosis**
• high morbidity and mortality in patients with sustained AKI and multi-organ failure

---

## Chronic Kidney Disease

**Definition**
- progressive and irreversible loss of kidney function
- abnormal markers (Cr, urea)
  - GFR <60 mL/min for >3 mo; or
  - kidney pathology seen on biopsy; or
  - decreased renal size on U/S (kidneys <9 cm)
- clinical features of CKD
  - volume overload and HTN
  - electrolyte and acid-base balance disorders (e.g. metabolic acidosis)
  - uremia

### Table 13. Stages of CKD (KDIGO, 2013)

</tr>
</tbody>
</table>

The numbers in the boxes are a reflection of the risk of progression and are a guide to the frequency of monitoring/year

"D" is added to G5 for patients requiring dialysis

Classification is based on cause, GFR, and amount of albuminuria

Rate of progression and risk of complications are determined by the cause of CKD

**Management of Chronic Kidney Disease**

- **diet**
  - preventing HTN and volume overload
  - Na+ and water restriction
  - preventing electrolyte imbalances
  - K+ restriction (40 mEq/d)
  - PO4³⁻ restriction (1 g/d)
  - avoid extra-dietary Mg²⁺ (e.g. antacids)
  - preventing uremia and potentially delaying decline in GFR
  - protein restriction with adequate caloric intake in order to limit endogenous protein catabolism
- **medical**
  - adjust dosages of renally excreted medications
  - HTN: ACEI (target 130/80 or less), loop diuretics when GFR <25 mL/min
  - dyslipidemia: statins
  - calcium and phosphate disorders:
    - calcium supplements (e.g. TUMS®) treats hypocalcemia when given between meals and binds phosphate when given with meals
    - consider calcitriol (1,25-dihydroxy-vitamin D) if hypocalcemic
    - sevelamer (phosphate binder) if both hypercalcemic and hyperphosphatemic
    - vitamin D analogues are being introduced in the near future
    - cinacalcet for hyperparathyroidism (sensitizes parathyroid to Ca²⁺, decreasing PTH)
  - metabolic acidosis: sodium bicarbonate
  - anemia: erythropoietin injections (Hct <30%); target Hct 33-36%
  - clotting abnormalities: DDAVP if patient has clinical bleeding or invasive procedures (acts to reverse platelet dysfunction)
  - dialysis (hemodialysis, peritoneal dialysis)
  - renal transplantation

---

### Incidence of Etiologies of CKD

| DM | 42.9% |
| HTN | 26.4% |
| Glomerulonephritis | 9.9% |
| Other/Unknown | 7.7% |
| Interstitial nephritis/ Pyelonephritis | 4.0% |
| Cystic/Hereditary/Congenital | 3.1% |
| Secondary GN/Vasculitis | 2.4% |

### Management of Complications of CKD

**NEPHRON**

- Low-nitrogen diet
- Electrolytes: monitor K⁺
- pH: metabolic acidosis
- NRCs: manage anemia with erythropoietin
- Osteodystrophy: give calcium between meals (to increase Ca²⁺) and calcium with meals (to bind and decrease PO4³⁻)
- Vitamin D analogues are being introduced in the near future
- Cinacalcet for hyperparathyroidism (sensitizes parathyroid to Ca²⁺, decreasing PTH)
- Metabolic acidosis: sodium bicarbonate
- Anemia: erythropoietin injections (Hct <30%); target Hct 33-36%
- Clotting abnormalities: DDAVP if patient has clinical bleeding or invasive procedures (acts to reverse platelet dysfunction)
- Dialysis (hemodialysis, peritoneal dialysis)
- Renal transplantation

### Renin Angiotensin System Blockade and Cardiovascular Outcomes in Patients with Chronic Kidney Disease and Proteinuria: A Meta-Analysis

**Am Heart J** 2008;155:791-805

**Purpose:** To evaluate the role of RAS blockade in improving cardiovascular CV outcomes in patients with CKD.

**Study Selection:** Randomized controlled trials that analyzed CV outcomes in patients with CKD/proteinuria treated with RAS blockade (ACEI/ARB). RAS blockade-based therapy was compared with placebo and control therapy (β-blocker, calcium-channel blockers, and other antihypertensive-based therapy) in the study.

**Results:** Twenty-five trials (n=45,758) were included. Compared to placebo, RAS blockade reduced the risk of heart failure in patients with diabetic nephropathy. In patients with non-diabetic CKD, RAS blockade decreased CV outcome compared to control therapy.

**Conclusions:** RAS blockade reduced CV outcomes in diabetic nephropathy as well as non-diabetic CKD.

---

NP34 Nephrology
Acute Kidney Injury/Chronic Kidney Disease

Essential Med Notes 2015
Prevention of Progression
- as above
- control of HTN, DM, cardiovascular risk factors (e.g. smoking cessation)
- avoid nephrotoxins
- address reversible causes of AKI

End Stage Renal Disease
- end stage renal disease represents a decline in kidney function which can occur over days to weeks (AKI), over months to years (CKD), or as a combination of the two

Presentation of End Stage Renal Disease

1. Volume Overload
- due to increase in total body Na⁺ content
- signs: weight gain, HTN, pulmonary or peripheral edema

2. Electrolyte Abnormalities
- high
  - K⁺ (decreased renal excretion, increased tissue breakdown)
  - PO₄⁻³ (decreased renal excretion, increased tissue breakdown)
  - Ca²⁺ (rare; happens during recovery phase after rhabdomyolysis-induced AKI or in settings where hypercalcemia contributes to renal failure, such as in multiple myeloma or sarcoidosis)
  - uric acid
- low
  - Na⁺ (failure to excrete excessive water intake)
  - Ca²⁺ (decreased Vit D activation, hyperphosphatemia, hypoalbuminemia)
  - HCO₃⁻ (especially with sepsis or severe heart failure)

3. Uremic Syndrome
- manifestations result from retention of urea and other metabolites as well as hormone deficiencies

Figure 19. Signs and symptoms of end stage renal disease
Complications
- CNS: decreased LOC, stupor, seizure
- CVS: cardiomyopathy, CHF, arrhythmia, pericarditis, atherosclerosis
- GI: peptic ulcer disease, gastroduodenitis, AVM
- hematologic: anemia, bleeding tendency (platelet dysfunction), infections
- endocrine
  - decreased testosterone, estrogen, progesterone
  - increased FSH, LH
- metabolic
  - renal osteodystrophy: secondary increased PTH due to decreased Ca^{2+}, high PO_{4}^{3-}, and low active vitamin D
    - osteitis fibrosa cystica
  - hypertriglyceridemia, accelerated atherogenesis
  - decreased insulin requirements, increased insulin resistance
- dermatologic: pruritus, ecchymosis, hematoma, calciphylaxis (vascular Ca^{2+} deposition)

Renal Replacement Therapy

Dialysis

*Unresponsive to medications

- **hemodialysis**: blood is filtered across a semipermeable membrane removing accumulated toxic waste products, solutes, excess fluid (ultrafiltration), and restoring buffering agents to the bloodstream
  - available as intermittent (e.g. 3x/wk), continuous (CVVHD) or sustained low efficiency (SLED)
  - can be delivered at home or in-center, nocturnal
  - vascular access can be achieved through a central line, an artificial graft, or an AV fistula
  - patients with CKD should be referred for surgery to attempt construction of a primary AV fistula when their eGFR is <20 mL/min, the serum Cr level quoted as >4.0 mg/dL (>350 µmol/L), or within 1 yr of an anticipated need

- **peritoneal dialysis**: peritoneum acts as a semipermeable membrane similar to hemodialysis filter
  - advantages: independence, fewer stringent dietary restrictions, better rehabilitation rates
  - available as continuous ambulatory (CAPD; four exchanges per day) or cyclic (CCPD; machine carries out exchanges overnight)
  - refer patients with chronic renal disease to a nephrologist early on to facilitate treatment and plan in advance for renal replacement therapy (RRT)

How to Write Dialysis Orders
(MUST BE INDIVIDUALIZED)

- Filter Type (e.g. F20)
- Length (e.g. 4 h 3x/wk or 2 h daily)
- Q Blood Flow (max 500 cc/min)
- Ultrafiltration (e.g. 2 L or to target dry weight)
- Na^+ 140 (can be adjusted by starting at 155 and “ramping” down to minimize cramping)
- K^+ (based on serum K^+)
  - Serum K^+  Dialysate
    - <3.5  3.5
    - >3.5  1.5

- Ca^{2+} 1.25
- HCO_{3}– 40
- Heparin (none, tight [500 U/h] or full [1000 U/h])
- IV fluid to support BP (e.g. N/S)

</tbody>
</table>

Renal Transplantation

- provides maximum replacement of GFR
- preferred modality of RRT in CKD, not AKI
  - best way to reverse uremic signs and symptoms
  - only therapy shown to improve survival in CKD patients with ESRD
- native kidneys usually left in situ
- 2 types: deceased donor, living donor (related or unrelated)
- kidney transplanted into iliac fossa, transplant renal artery anastomosed to external iliac artery of recipient
- 1 yr renal allograft survival rates ≥90%

Complications

- leading causes of late allograft loss: interstitial fibrosis/tubular atrophy (IFTA) and death with functioning graft
- #1 cause of mortality in transplanted patients is cardiovascular disease
- immunosuppressant drug therapy: side effects include infections, malignancy (skin, Kaposis’s sarcoma, post-transplant lymphoproliferative disorder)
- acute rejection: graft site tenderness, rise in Cr, oliguria, ± fever, although symptoms are uncommon
- de novo GN (usually membranous)
- new-onset DM (often due to prednisone use)
- cyclosporine or tacrolimus nephropathy (refer to Small Vessel Disease, NP18)
- chronic allograft nephropathy
  - early allograft damage caused by episodes of acute rejection and acute peritransplant injuries
  - immunologic and nonimmunologic factors (HTN, hyperlipidemia, age of donor, quality of graft, new onset DM)
  - transplant glomerulopathy from antibody injury causes nephrotic proteinuria
- CMV (cytomegalovirus) infection and other opportunistic infections usually occur between 1 and 6 mo post-transplant
- BK virus (polyoma virus) nephropathy can result from over-immunosuppression and lead to graft loss

When to Initiate Dialysis

<table>
<thead>
<tr>
<th>CrCl (mL/min)</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;20</td>
<td>Educate patient regarding dialysis; if not a candidate for peritoneal dialysis, make arrangements for AV fistula</td>
</tr>
<tr>
<td>&lt;15</td>
<td>Weigh risk and benefits for initiating dialysis</td>
</tr>
<tr>
<td>&lt;10</td>
<td>Dialysis should be initiated</td>
</tr>
</tbody>
</table>

NOTE

- Cockcroft-Gault equation (or MDRD equation) should be used to measure kidney function
- Monitor for uremic complications
- Significant benefits in quality of life can occur if dialysis started before CrCl < 15 mL/min
- It is unclear whether patients who start dialysis early have increased survival
- A preemptive transplant can be considered if patient is stable, in order to avoid dialysis

Commonly Used Immunosuppressive Drugs

- Calcineurin inhibitors
  - Cyclosporine
  - Tacrolimus
- Antiproliferative medications
  - Mycophenolate mofetil
  - Azathioprine
- Other agents
  - Sirolimus
  - Prednisone
- Anti-lymphocyte antibodies
  - Thymoglobulin
  - Basiliximab

Survival Among Nocturnal Home Hemodialysis Patients Compared to Kidney Transplant Recipients

- Nephrol Dial Transplant 2008;24:2915-2919
- Study: Retrospective, matched cohort with 4-5 yr average follow up.
- Population: 177 nocturnal home dialysis (NHD) patients (mean age 46, 68% white) were matched to 533 deceased donor transplant (DTX) patients and 533 live donor (LTX) transplant patients (1:3:3 ratio).
- Intervention: Nocturnal home dialysis vs. live or deceased donor transplant.
- Outcome: Primary outcome was all cause mortality.
- Results: No significant difference in survival or hazard ratio between NHD and DTX. Significant survival benefit for patients undergoing LTX vs. NHD. Significant mortality hazard ratio reduction with LTX (0.51) with no difference in hazard ratio for DTX vs. NHD reference.
- Conclusion: NHD has comparable mortality to DTX, but is inferior to LTX.

<td>In non-diabetic nephropathy, ACEI were renoprotective in patients with non-nephrotic range proteinuria.</td>
</tr>
<tr>
<td>REIN2</td>
<td>Lancet 2005; 365:939-46</td>
<td>In non-diabetic nephropathy already on ACEI, no further benefit from intensified BP control (sBP/dBP&lt;130/80 mmHg) by adding a CCB vs. conventional BP control (sBP&lt;90 mmHg) on ACEI alone.</td>
</tr>
<tr>
<td>RENAA</td>
<td>NEJM 2001; 345:861-9</td>
<td>Losartan conferred significant renal benefits in patients with type 2 DM and nephropathy and was generally well-tolerated.</td>
</tr>
<tr>
<td>RENAL</td>
<td>NEJM 2009; 361:1627-38</td>
<td>High intensity continuous renal-replacement therapy in AKI does not improve survival or outcomes compared to low intensity treatment, and is associated with higher rates of hypophosphatemia.</td>
</tr>
</tbody>
</table>
ROAD
JASN 2007; 18:1889-98
Up titration of either ACEI benazepril or ARB losartan to optimal anti-proteinuria doses conferred benefit on renal outcome in patients without DM who had proteinuria and renal insufficiency

ROADMAP
NEJM 2011; 364:907-17
The use of the ARB olmesartan was more effective than placebo in delaying the onset of microalbuminuria in patients with type 2 DM, normoalbuminuria, and good blood pressure control; however, a higher rate of fatal cardiovascular events was found amongst patients with preexisting coronary heart disease in the olmesartan group.

SHARP
Lancet 2011; 377:2181-92
Randomized placebo-controlled trial in patients with CKD and no history of MI or coronary revascularization took simvastatin 20 mg plus ezetimibe 10 mg daily vs. matching placebo; simvastatin 20 mg plus ezetimibe 10 mg daily resulted in reduction of LDL cholesterol with associated reduction of major atherosclerotic events in patients with CKD

TREAT
NEJM 2009; 361:2019-32
Patients with type 2 DM, CKD, and anemia were randomized to darbepoetin targeting a hemoglobin of 13 g/dL or placebo; darbepoetin did not reduce the risk of death, a cardiovascular event, or a renal event, and was associated with an increased risk of stroke

The Neurological Exam

General Exam and Mental Status

- **vitals:** pulse (especially rhythm), BP, temperature
- **H&N:** meningismus, head injury/bruises (signs of basal skull fracture: Battle's sign, raccoon eyes, hemotympanum, CSF rhinorrhea/otorrhea), tongue biting
- **CVS:** carotid bruits, heart murmurs
- **mental status:** orientation (person, place, time), LOC (GCS)
  - GCS/15 – Motor/6, Verbal/5 (T= intubated), Eyes/4
- **cognition**
  - Folstein MMSE – /30 (note: dementia is a clinical diagnosis and is not diagnosed by cognitive testing)
  - MoCA – /30 (≥26 is considered normal)
- **clock drawing** (frontal lobe testing (for perseveration)
- **GCS/15**

Cranial Nerves Exam

- **olfactory** (CN I): odor sensation (test each nostril separately)
- **optic** (CN II)
  a. visual acuity: test each eye individually using best corrected vision
  b. visual fields
  c. pupil: direct and consensual pupillary reaction (afferent limb), accommodation, swinging flashlight test (see Relative Afferent Pupillary Defect, *Ophthalmology*, OP33)
  d. fundoscopy: optic disc edema, optic disc pallor, venous pulsations, hemorrhages
- **extraocular movements (EOM)**
  a. **oculomotor** (CN III): levator palpebrae superioris, medial rectus, superior rectus, inferior rectus, inferior oblique, efferent limb of pupillary light response
  b. **trochlear** (CN IV): superior oblique
  c. **abducens** (CN VI): lateral rectus
- **trigeminal** (CN V)
  a. sensory: V1 (above supraorbital ridge), V2 (buccal area), V3 (mandible), corneal reflex (afferent)
  b. motor: temporals, masseter, pterygoids, jaw jerk reflex
- **facial** (CN VII)
  a. sensorimotor: muscles of facial expression, hyperacusis (stapedius), corneal reflex (efferent)
  b. visceral sensory: taste of anterior 2/3 of tongue
  c. visceral motor: salivary and lacrimal glands
- **vestibulocochlear** (CN VIII)
  a. vestibular: nystagmus, caloric reflexes
  b. cochlear: Kinne, Weber
- **glossopharyngeal** (CN IX) and **vagus** (CN X): palatal elevation, gag reflex, vocal cord function, swallowing, taste at posterior third of tongue
- **accessory** (CN XI): trapezius and sternocleidomastoid strength
- **hypoglossal** (CN XII): tongue muscle bulk, fasciculations, strength

Motor Exam

- **bulk:** atrophy, asymmetry
- **abnormal movements:** asymmetry of movement (suggests weakness, e.g. satellite sign), tremors, chorea, dystonia, hemiballismus, myoclonus, athetosis, tics, fasciculations
- **abnormal posturing:** decerebrate, decorticate
- **tone:** hypotonia (flaccid), hypertonia (spasticity, rigidity, paratonia), cogwheeling (rigidity + tremor)
- **strength**
- **reflexes:** deep tendon reflexes, abdominal reflexes, primitive reflexes, Babinski, Hoffman, clonus

**SIGNS AND SYMPTOMS**

**SENSORY EXAM**

- **Primary Sensation**
  - Spinthalamic tract: pain and temperature
  - Dorsal column: proprioception and vibration

- **Cortical Sensation**
  - Graphesthesia, stereognosis, extinction, 2-point discrimination

**TESTS**

**EMG**
- Denervation and reinnervation
- Signs of demyelination ± axonal loss
- Decremental response in MG, Jitter on single fiber EMG
- Small, short motor potentials

**NCS**
- Normal
- Abnormal

**Muscle enzyme**
- Normal
- Normal
- Increased

**Primitive Reflexes**
- Grasp, palmomental, root, glabellar tap, snout

**Deep Tendon Reflexes**
- C5/6: Biceps
- C6: Brachioradialis
- C7: Triceps
- C8: Finger flexors
- L2/3: Hip adductors
- L3/4: Knee extensors
- L5/S1: Plantar flexion

**Deep Tendon Reflex Scoring**
- 0: Absent
- 1+: Depressed
- 2+: Normal
- 3+: Increased
- 4+: Clonus (≥4 beats)
Coordination Exam and Gait

- **coordination exam**
  - finger-to-nose, heel-to-shin, rapid alternating movements

- **stance and gait**
  - gait: antalgic, hemiplegic, ataxic, apraxic, festination, foot drop, broad-based
  - tandem gait (heel-to-toe walking)
  - Romberg test
  - pull test for postural instability

### Basic Anatomy Review

![Medulla](image1)

- 2 Spinohemispheric tract
- 3 Medial lemniscus
- 4 Reticular formation
- 5 Nucleus of spinal tract of trigeminal (V) nerve (descending)
- 6 Spinal tract of trigeminal (V) nerve
- 8 Fasciculus cuneatus
- 9 Nucleus gracilis
- 10 Fasciculus gracilis
- 11 Central canal
- 12 Arcuate fibers

![Pons](image2)

- 13 Pontine nucleus
- 14 Abducens (VI) nerve fibers
- 15 Nucleus of facial (VII) nerve (motor)
- 16 Facial (VII) nerve fibers
- 17 Trigeminal (V) nerve fibers
- 18 Nucleus of abducens (VI) nerve
- 19 Nucleus of spinal tract of trigeminal (V) nerve
- 20 Lateral vestibular nucleus
- 21 Middle cerebellar peduncle
- 22 Fourth ventricle

![Midbrain](image3)

- 23 Interpeduncular fossa
- 24 Oculomotor (III) nerve fibers
- 25 Cerebral peduncle
- 26 Substantia nigra
- 27 Red nucleus
- 28 Edinger-Westphal nuclei
- 29 Oculomotor (III) nucleus complex (motor)
- 30 Cerebral aqueduct
- 31 Pretectal area
- 32 Superior colliculus

### Interpreting a Slow or Uncoordinated Rapid Alternating Movement (RAM)

- Slow RAMs without fatiguing is suggestive of weakness (especially if it is asymmetric)
- Slow RAMs with fatiguing (i.e. decreasing amplitude over time) is suggestive of Parkinsonism
- Uncoordinated RAM is suggestive of cerebellar disorder (i.e. ataxia and irregularly irregular rhythm) or ideomotor apraxia

### Romberg Test

- Stable with eyes open and closed = normal
- Stable with eyes open, falls with eyes closed = positive Romberg, suggesting loss of joint position sense

### Common Cerebellar Findings

- Frontal executive dysfunction/disinhibition, scanning speech, nystagmus, hypo- or hypermetric saccades, hypotonia, pendular reflexes, terminal tremor, ataxic finger-nose/heel-shin/tandem, wide based stance, positive rebound

Figure 9. Dermatome map

Myotomes
C5 – Shoulder abduction/elbow flexion
C6 – Wrist extensors
C7 – Elbow extension
C8 – Squeeze hand
T1 – Finger abduction
T2-9 – Intercostal (abdominal reflexes)
T9-10 – Upper abdominals
T11-12 – Lower abdominals
L2 – Hip flexion
L3 – Hip adduction
L4 – Knee extension and ankle dorsiflexion
L5 – Ankle dorsiflexion and big toe extension
S1 – Plantarflexion
Lumbar Puncture

Indications
- diagnostic: CNS infection (meningitis, encephalitis), inflammatory disorder (MS, Guillain-Barré, vasculitis), subarachnoid hemorrhage (if CT negative), CNS neoplasm (neoplastic meningitis)
- therapeutic: to administer anesthesia, chemotherapy, contrast media; to decrease ICP (pseudotumor cerebri, normal pressure hydrocephalus)

Contraindications
- mass lesion causing ICP – could lead to cerebral herniation
  - require CT first
- infection over LP site/suspected epidural abscess
- low platelets (<50,000) or treatment with anticoagulation (high INR or aPTT)
- uncooperative patient

Complications
- tonsillar herniation (rare)
- subdural hemorrhage
- transient 6th nerve palsy
- post-LP headache (5-40%): worse when upright, better supine; generally onset within 24 h
  - prevention: smaller gauge (i.e. 22) needle, reinsert stylet prior to needle removal, blunt-ended needle
  - symptomatic treatment: caffeine and sodium benzoate injection
  - corrective treatment: blood patch (autologous)
- spinal epidural hematoma
- infection

LP Tubes
- tube #1: cell count and differential: RBCs, WBCs, and differential
  - xanthochromia (yellow bilirubin pigmentation implies recent bleed into CSF)
- tube #2: chemistry: glucose (compare to serum glucose) and protein
- tube #3: microbiology: Gram stain and C&S
  - specific tests depending on clinical situation/suspicion
    - viral: PCR for herpes simplex virus (HSV) and other viruses
    - bacterial: polysaccharide antigens of H. influenzae, N. meningitidis, S. pneumoniae
    - fungal: Cryptococcal antigen, culture
    - TB: acid-fast stain, TB culture, TB PCR
- tube #4: cytology: for evidence of malignant cells
- tube #5: cell count: compare RBC count to that of tube #1
  - note: tube 4 or 5 can be sent for repeat cell count

Approach to Common Presentations

Weakness

Approach
- mode of onset: abrupt (vascular, toxic, metabolic), subacute (neoplastic, infective, inflammatory), insidious (hereditary, degenerative, endocrinologic, neoplastic)
- course: worse at onset (vascular), progressive (neoplastic, degenerative, infective), episodic (vascular, inflammatory), activity dependent (NMJ, muscular)
- pattern: objective vs. subjective, generalized vs. localized, asymmetric vs. symmetric, proximal vs. distal, UMN vs. LMN, peripheral vs. myotomal
- associated symptoms: sensory symptoms, cortical symptoms, spinal symptoms (i.e. bowel/bladder dysfunction), signs/symptoms specific to various etiologies
- history: family history, developmental history, medications, risk factors, recent/preceding exposures
- investigations for LMN: NCS/EMG
- investigations for UMN: imaging (brain and/or spinal cord)
Differential Diagnosis
- objective muscle weakness; also, differentiate between true muscle weakness vs. fatigue
  - localized
    - UMN (leukodystrophy, vasculitis, abscess, brain tumor, vitamin B12 deficiency, MS, stroke)
    - radicular pain (i.e. nerve root)
    - anterior horn cell pain (spinal muscular atrophy, ALS, polio, paraneoplastic, lead toxicity)
    - peripheral neuropathy (peroneal muscle atrophy, GBS, leprosy, amyloid, myeloma, DM, lead toxicity)
  - chronic illness (cardiac, pulmonary, anemia, infection, malignancy)
  - depression, deconditioning
- if loss of passive motion, consider intra-articular, peri-articular, or extra-articular causes

Numbness/Altered Sensation

Approach
- positive sensory symptoms: paresthesia/dysesthesia = tingling, pins and needles, prickling, burning, stabbing
- negative sensory symptoms: hypoesthesia/anesthesia = numbness, diminution, or absence of feeling
- determine distribution of sensory loss
  - nerve root vs. peripheral nerve?
  - symmetric stocking-glove pattern? (indicative of distal symmetric polyneuropathy)
  - anterior-posterior spinal cord dissociation
- investigations: NCS, vitamin B12 levels, imaging based on associated findings

Differential Diagnosis
- cerebral: stroke, demyelination, tumor
  - associated symptoms: hemiplegia, aphasia, apraxia
- brainstem: stroke, demyelination, tumor
  - associated symptoms: diplopia, vertigo, dysarthria, dysphagia
- spinal cord/radiculopathy: cord infarction, tumor, MS, syringomyelia, vitamin B12 deficiency, disc lesion
  - associated symptoms: back/neck pain, weakness (paraparesis or Brown-Séquard pattern)
- neuropathy: focal compressive neuropathy (based on location and distribution), DM, uremia, vasculitis, vitamin B12 deficiency, HIV, Lyme disease, alcohol, paraneoplastic, amyloid

Cranial Nerve Deficits

CN I: Olfactory Nerve

Clinical Features
- absence of sense of smell associated with a loss of taste

Differential Diagnosis
- nasal: physical obstruction
  - heavy smoking, chronic rhinitis, sinusitis, neoplasms, septal deformity, choanal atresia, vestibular stenosis, foreign body
- olfactory neuroepithelial: destruction of receptors or their axon filaments
  - influenza, herpes simplex, interferon treatment of hepatitis C virus, atrophic rhinitis (leprosy)
- central: lesion of olfactory pathway
  - Kallmann’s syndrome, albinism, head injury, cranial surgery, SAH, chronic meningeal inflammation, meningioma, aneurysm, PD, stroke, MS
- endocrine/metabolic
  - DM, adrenal hypo/hyperfunction, pseudohypoparathyroidism, hypothyroidism, renal/liver failure, vitamin deficiency
**CN II: Optic Nerve**

- see *Neuro-Ophthalmology*, N12

**CN III: Oculomotor Nerve**

**Clinical Features**
- ptosis, resting eye position is “down and out” (depressed and abducted), pupil dilated (mydriasis)
- vertical and horizontal diplopia; paralysis of adduction, elevation, and depression

**Differential Diagnosis**
- PComm aneurysm: early mydriasis, then CN III palsy
- cavernous sinus (internal carotid aneurysm, meningioma, sinus thrombosis): associated with deficits in other CNs near the cavernous sinus
- ischemia of CN III (DM, temporal arteritis, HTN, atherosclerosis): pupil sparing CN III palsy
- midbrain lesion: complete unilateral CN III palsy with bilateral weakness of the superior rectus and ptosis with contralateral pyramidal signs ± mydriasis
- orbital lesion: associated with optic neuropathy, chemosis, proptosis
- other (inflammatory, infection, neoplasia, uncal herniation, trauma)

![Figure 11. Cavernous sinus (coronal view)](image)

**CN IV: Trochlear Nerve**

**Clinical Features**
- vertical and torsional diplopia; defect of intorsion and depression
- patient may complain of difficulty going down stairs or reading

**Differential Diagnosis**
- common: ischemic (DM, HTN), idiopathic, trauma (TBI or surgical), congenital
- other: cavernous sinus lesion, superior orbital fissure (tumor, granuloma)

**CN V: Trigeminal Nerve**

**Clinical Features**
- ipsilateral facial numbness, weakness of muscles of mastication (V3 only) with pterygoid deviation towards the side of the lesion

**Differential Diagnosis**
- brainstem (ischemia, tumor, syringobulbia, demyelination)
- peripheral (tumor, aneurysm, chronic meningitis, metastatic infiltration of nerve)
- trigeminal ganglion (acoustic neuroma, meningioma, fracture of middle fossa)
- cavernous sinus (carotid aneurysm, meningioma, sinus thrombosis)
- trauma
- note: other CN V lesions that cause facial pain = trigeminal neuralgia, herpes zoster

**CN VI: Abducens Nerve**

**Clinical Features**
- resting inward deviation (esotropia)
- horizontal diplopia; defect of lateral gaze
Differential Diagnosis

- **pons** (infarction, hemorrhage, demyelination, tumor): associated with facial weakness and contralateral pyramidal signs
- **tentorial orifice** (compression, meningioma, trauma): false localizing sign of increased ICP
- **cavernous sinus** (carotid aneurysm, meningioma, sinus thrombosis)
- **ischemia of CN VI** (DM, temporal arteritis, HTN, atherosclerosis)
- **congenital** (Duane’s syndrome)

**Differential Diagnosis**

- idiopathic = Bell’s palsy, 80-90% of cases (see Otolaryngology, OT23)
  - most often related to HSV, but other viruses may be implicated (CMV, herpes zoster, EBV)
- other: temporal bone fracture, EBV, Ramsay Hunt (HSV), otitis media/mastoiditis, sarcoidosis, DM mononeuropathy, parotid gland disease, Lyme meningitis, HIV

**CN VII: Facial Nerve**

**Clinical Features**

- **LMN lesion**: ipsilateral facial weakness (facial droop, flattening of forehead, inability to close eyes, flattening of nasolabial fold)
- **UMN lesion**: contralateral facial weakness with forehead sparing (due to bilateral frontalis innervation)

**Differential Diagnosis**

- impaired lacrimation, decreased salivation, numbness behind auricle, hyperacusis, taste dysfunction of anterior 2/3 of tongue

**Differential Diagnosis**

- **idiopathic** = Bell’s palsy, 80-90% of cases (see Otolaryngology, OT23)
  - most often related to HSV, but other viruses may be implicated (CMV, herpes zoster, EBV)
- **other**: temporal bone fracture, EBV, Ramsay Hunt (HSV), otitis media/mastoiditis, sarcoidosis, DM mononeuropathy, parotid gland disease, Lyme meningitis, HIV

**Figure 12. UMN vs. LMN facial nerve palsy**

**CN VIII: Vestibulocochlear Nerve**

- see Otolaryngology, OT14

**CN IX: Glossopharyngeal Nerve**

**Clinical Features**

- unilateral lesion is rare
- taste dysfunction in posterior 1/3 of tongue
- absent gag reflex and dysphagia

**Disorders**

- **glossopharyngeal neuralgia**: sharp paroxysmal pain of posterior pharynx radiating to ear, triggered by swallowing
  - treated with carbamazepine or surgical ablation of CN IX

**Uvula deviation is away from the side of a LMN CN X lesion due to impaired ipsilateral palatal elevation**
CN X: Vagus Nerve

Clinical Features
- oropharyngeal dysphagia (transfer dysphagia) due to palatal and pharyngeal weakness
  - neuromuscular causes of dysphagia
    - CNS: stroke, cerebral palsy, tumor, trauma, PD, AD, MS
    - CN: DM, laryngeal nerve palsy, polio, ALS
    - myopathic/NMJ: dermatomyositis, polymyositis, MG, sarcoidosis
  - other causes of dysphagia: see Gastroenterology, G8
- dysarthria: inability to produce understandable speech due to impaired phonation and/or resonance

CN XI: Accessory Nerve

Clinical Features
- LMN lesion: paralysis of ipsilateral trapezius and sternocleidomastoid (ipsilateral shoulder drop, weakness on turning head to contralateral side)
- UMN lesion: paralysis of ipsilateral sternocleidomastoid and contralateral trapezius

CN XII: Hypoglossal Nerve

Clinical Features
- LMN lesion: tongue deviation towards lesion; ipsilateral tongue atrophy and fasciculations (if chronic)
- UMN lesion: tongue deviation away from lesion; absence of atrophy and fasciculations

Table 5. Cranial Nerve Examination and Associated Deficits

<table>
<thead>
<tr>
<th>Cranial Nerve</th>
<th>Recommended Physical Exams</th>
<th>Signs/Symptoms of Deficit</th>
</tr>
</thead>

</tbody>
</table>

If you suspect the diagnosis of giant cell arteritis do not wait for biopsy results
Begin treatment immediately

NAION can be caused by use of Sildenafil (Viagra®) in rare cases
Optic Disc Atrophy

- **etiologies:** glaucoma, AION, compressive tumor, optic neuritis, Leber’s hereditary optic neuropathy, congenital
- **presentation:** disc pallor, low visual acuity, peripheral vision defect, decreased color vision
- **treatment:** none (irreversible), aim to prevent

Abnormalities of Visual Field

![Visual Fields Defects](image)

- Right anopsia (right optic nerve lesion)
- Right anopsia and left upper quadrantanopsia (junctional scotoma)
- Bitemporal hemianopsia (chiasmal lesion)
- Left homonymous hemianopsia (right optic tract lesion)
- Left upper quadrantanopsia (right temporal lesion)
- Left lower quadrantanopsia (right parietal lesion)

Disorders of Eye Movements

Abnormalities of Eye Movements

Pathophysiology
- horizontal gaze: FEF → contralateral PPRF (midbrain/pons) → eyes saccade away from FEF
- vertical gaze: cortex → rostral interstitial nucleus in the MLF (midbrain)

Clinical Features
- unilateral lesion in one FEF → eyes deviate toward the side of the lesion
  - can be overcome with doll’s eye maneuver
- unilateral lesion in the PPRF → eyes deviate away from the lesion
  - cannot be overcome with doll’s eye maneuver if CN VI nucleus lesion as well
- seizure involving a FEF: eyes deviate away from the focus

Etiology
- common: infarcts (frontal or brainstem), MS, tumors

Internuclear Ophthalmoplegia

Pathophysiology
- results from a lesion in MLF which disrupts coordination between CN VI nucleus in pons and the contralateral CN III nucleus in midbrain → disrupts conjugate horizontal gaze

Clinical Features
- horizontal diplopia on lateral gaze, oscillopsia
- on gaze away from the side of the lesion
  - ipsilateral adduction defect
  - contralateral abduction nystagmus
- cannot be overcome by caloric testing
- accommodation reflex intact
- may be bilateral (especially in MS)

Etiology
- common: MS, brain stem infarct

Investigations
- MRI

Internuclear Ophthalmoplegia DDx by Age
- Children: craniopharyngioma
- Middle aged (20s to 50s): pituitary mass
- Elderly (>60 yr): meningioma

Bitemporal Hemianopsia DDx by Age
- In homonymous hemianopsia, more congruent deficits are caused by more posterior lesions. Mucular sparing may occur with occipital lesions
- In homonymous hemianopsia, more congruent deficits are caused by more posterior lesions. Mucular sparing may occur with occipital lesions
- A lesion in a cerebral hemisphere causes eyes to “look away” from the hemiplegia, and to look towards the lesion
- A lesion in the brainstem causes the eyes to “look toward” the side of the hemiplegia, and to look away from the lesion

Internuclear Ophthalmoplegia

- Check all hemiplegic patients for homonymous hemianopsia (ipsilateral to side of hemiplegia)
- Check all hemiplegic patients for homonymous hemianopsia (ipsilateral to side of hemiplegia)
- Check all hemiplegic patients for homonymous hemianopsia (ipsilateral to side of hemiplegia)

Bitemporal Hemianopsia

- Children: craniopharyngioma
- Middle aged (20s to 50s): pituitary mass
- Elderly (>60 yr): meningioma

In homonymous hemianopsia, more congruent deficits are caused by more posterior lesions. Mucular sparing may occur with occipital lesions

Internuclear Ophthalmoplegia

- In homonymous hemianopsia, more congruent deficits are caused by more posterior lesions. Mucular sparing may occur with occipital lesions
- In homonymous hemianopsia, more congruent deficits are caused by more posterior lesions. Mucular sparing may occur with occipital lesions
- In homonymous hemianopsia, more congruent deficits are caused by more posterior lesions. Mucular sparing may occur with occipital lesions
Diplopia

Etiology – Monocular
• mostly due to relatively benign optical problems (refractive error, cataract) or functional

Etiology – Binocular (due to ocular misalignment)
• muscle
  ▪ Graves’ ophthalmopathy
  ▪ EOM restriction/entrapment
• neuromuscular junction
  ▪ MG (see Myasthenia Gravis, N37)
• cranial nerve palsy (see Cranial Nerve Deficits, N8)
• INO (see Intranuclear Ophthalmoplegia, N13)
• other
  ▪ orbital trauma (orbital floor fracture), tumor, infection, inflammation
  ▪ Miller-Fisher variant of GBS
  ▪ Wernicke’s encephalopathy
  ▪ leptomeningeal disease

Approach to Diplopia
• monocular vs. binocular
• horizontal vs. vertical vs. oblique diplopia
• direction of gaze that exacerbates diplopia
• corrective head movements

Workup
• may observe isolated 4th or 6th nerve palsy for a few weeks, but workup if persistent or other symptoms develop
• indications for neuroimaging
  ▪ bilateral or multiple nerve involvement
  ▪ severe sudden onset headache (rule out aneurysm)

Nystagmus

• definition: rapid, involuntary, small amplitude movements of the eyes that are rhythmic in nature
• direction of nystagmus is labeled by the rapid component of the eye movement
• can be categorized by movement type (pendular, jerking, rotatory, coarse) or as physiological vs. pathological

Table 7. Nystagmus Features

*IM = intramuscular; IV = intravenous

- it is also important to consider occupational neurotoxic syndromes secondary to exposure to pesticides, solvents, and metals. Encephalopathy, extrapyramidal features, neurodegenerative diseases, and peripheral neuropathy are commonly encountered. Onset and progression of neurological diseases should be temporally related to neurotoxin exposure. Main toxins associated with neurotoxicity are listed below:

Neurologic Complications due to Toxic Injuries Related to Bariatric Surgery

- deficiencies of both fat- and water-soluble vitamins may occur following malabsorptive bariatric surgery
- patients who have undergone malabsorptive surgery should be monitored for late metabolic complications and neurological manifestations
Seizure Disorders and Epilepsy

Seizure

Definitions
- **seizure**: transient neurological dysfunction caused by excessive activity of cortical neurons, resulting in paroxysmal alteration of behavior and/or EEG changes
- **epilepsy**: chronic condition characterized by two or more unprovoked seizures

Classification

<table>
<thead>
<tr>

<td></td>
</tr>
</tbody>
</table>

Signs and Symptoms

- **partial seizures**
  - simple or complex can secondarily generalize, or simple → complex → generalized seizures
  - **simple (preserved LOC)**
    - motor: postural, phono-tory, forceful turning of eyes and/or head, focal muscle rigidity/jerking ± Jacksonian march (spreading to adjacent muscle groups)
    - sensory: unusual sensations affecting vision, hearing, smell, taste, or touch
    - autonomic: epigastric discomfort, pallor, sweating, flushing, piloerection, pupillary dilatation
    - psychiatric: symptoms rarely occur without impairment of consciousness and are more commonly complex partial
  - **complex (altered LOC)**
    - patient may appear to be awake but with impairment of awareness
    - classic complex seizure is characterized by automatisms such as chewing, swallowing, lip-smacking, scratching, fumbling, running, disrobing, and other stereotypic movements
    - other forms: dysphasic, dysmnesic (déjà vu), cognitive (disorientation of time sense), affective (fear, anger), illusions, structured hallucinations (music, scenes, taste, smells), epigastric fullness

- **generalized seizures (decreased LOC)**
  - **absence (petit mal)**: usually only seen in children, unresponsive for 5-10 s with arrest of activity, staring, blinking or eye-rolling, no post-ictal confusion; 3 Hz spike and slow wave activity on EEG
  - **clonic**: repetitive rhythmic jerking movements
  - **tonic**: muscle rigidity in flexion or extension
  - **tonic-clonic** (grand mal, generalized tonic-clonic [GTC])
    - prodrome of unease or irritability hours to days before the episode
    - tonic ictal phase: muscle rigidity
    - clonic ictal phase: repetitive violent jerking of face and limbs, tongue biting, cyanosis, frothing, incontinence
    - post-ictal phase: flaccid limbs, extensor plantar reflexes, headache, confusion, aching muscles, sore tongue, amnesia, elevated serum CK lasting hours
  - **myoclonic**: sporadic contractions localized to muscle groups of one or more extremities
  - **atonic**: loss of muscle tone leading to drop attack

Medical Emergency
- Status epilepticus can cause irreversible brain damage without treatment

Stroke is the most common cause of late-onset (>50 yr) seizures, accounting for 50-80% of cases

Seizures and Dementia
- Neurodegenerative diseases can underlie seizures; conversely, seizures can be a cause of dementia

Temporal lobe epilepsy is suggested by an aura of fear, olfactory or gustatory hallucinations, and visceral or déjà vu sensations

Frontoparietal cortex seizures are suggested by contralateral focal sensory or motor phenomena

Figure 16. Classification of seizures
NOTE: seizures can also be classified using age of onset (childhood/adolescence, adulthood/late [i.e. >age 30]), setting (sleep, upon awakening), EEG (focal, generalized)

</tbody>
</table>

*Pseudoseizures do not rule out seizures (not uncommon to present with both)

### Investigations
- CBC, electrolytes, fasting blood glucose, Ca²⁺, Mg²⁺, ESR, Cr, liver enzymes, CK, prolactin
- also consider toxicology screen, EtOH level, AED level (if applicable)
- CT/MRI (if new seizure without identified cause or known seizure history with new neurologic signs/symptoms)
- CT/MRI (if new seizure without identified cause or known seizure history with new neurologic signs/symptoms)
- LP (if fever or meningismus)
- EEG

### Treatment
- avoid precipitating factors
- indications for medical therapy (anticonvulsants): 2 or more unprovoked seizures, known organic brain disease, EEG with epileptiform activity, first episode of status epilepticus, abnormal neurologic examination or findings on neuroimaging
- psychosocial issues: stigma of seizures, education of patient and family, status of driver’s license, pregnancy issues
- safety issues: driving, operating heavy machinery, bathing, swimming alone
- consider surgical treatment if focal and refractory

## Status Epilepticus
- **definition**: unremitting seizure of greater than 5 min; or successive seizures without return to a baseline state
- **complications**: anoxia, cerebral ischemia and cerebral edema, rhabdomyolysis and renal failure, aspiration pneumonia/pneumonitis, death (20%)
- **initial measures**: ABCs, vitals, monitors, fingerprick glucose (STAT), ECG, nasal O₂, IV NS, IV glucose, IV thiamine, ABGs (if respiratory distress/cyanotic)
blood work: electrolytes, Ca\(^{2+}\), Mg\(^{2+}\), PO\(_4\)\(^{3-}\), glucose, CBC, toxicology screen, EtOH level, AED levels

focused history: onset, past history of seizures, drug and alcohol ingestion, past medical history, associated symptoms, witnesses/collateral history

physical exam (once seizures controlled): LOC, vitals, HEENT (mucosal rigidity, head trauma, tongue biting, papilledema), complete neurological exam, signs of neurocutaneous disorders, decreased breath sounds, cardiac murmurs or arrhythmias, urinary incontinence, MSK exam (rule out injuries)

Antiepileptic Drugs
- generalized-onset and partial-onset seizures: felbamate, lamotrigine, levetiracetam, retinamide, topiramate, valproate, zonisamide
- partial seizures (simple partial, complex partial, and secondarily generalized seizures): carbamazepine, gabapentin, lacosamide, oxcarbazepine, phenobarbital, phenytoin, pregabalin, primidone, tiagabine, vigabatrin (note: these drugs may exacerbate generalized seizures)
- absence seizures: ethosuximide

Disorders of Consciousness

Definition
- the minimally conscious state and the vegetative state are disorders of consciousness that can be acute and reversible or chronic and irreversible (Bernat, 2006)
- the vegetative state is defined as a state of wakefulness without awareness, while the minimally conscious state is described as wakefulness with transient low levels of awareness to stimuli
- the three main clinical features of vegetative state are:
  A. cycle of eye opening and closing (indicative of a sleep-wake cycle)
  B. complete lack of awareness of self or the environment (i.e. no evidence of sustained, reproducible, purposeful, or voluntary behavioral responses to visual, auditory, tactile, or noxious stimuli)
  C. complete or partial preservation of hypothalamic and brain stem autonomic functions
- those in a vegetative state also show no evidence of language comprehension or expression, and have bowel and bladder incontinence, but have variably preserved cranial-nerve and spinal reflexes
- a vegetative state is considered persistent if it lasts longer than 1 mo and permanent when it lasts longer than six mo for non-traumatic brain injuries and 1 yr for traumatic brain injuries

Etiology
- may develop suddenly (consequence of traumatic or non-traumatic injury), or gradually (in the course of a neurodegenerative disorder)
- may involve diffuse lesions to cortical neurons, thalami, or white matter tracts

Epidemiology
- vegetative state: 0.2-3.4 per 100,000
- minimally conscious state: 1.4 per 100,000

The locked-in syndrome is not a disorder of consciousness but rather a mimic; these individuals have normal sleep-wake cycles, normal levels of awareness, and may exhibit meaningful behavior (via vertical eye-movements and blinking), but are isolated due to quadriplegia and pseudobulbar palsy. They may also exhibit a locked-in syndrome that interferes with normal breathing, movement, and speech.

Rule out non-convulsive status epilepticus in any patient who is still unconscious >20 min post-ictal. Order a stat EEG if unsure.
### Behavioral Neurology

- see Psychiatry, PS16

**Major Neurocognitive Disorder** (formerly Dementia)

- see Psychiatry, PS17

**Definition**

- an acquired, generalized, and (usually) progressive impairment of cognitive function (i.e. memory, recall, orientation, language, abstraction) associated with impairment in activities of daily living (i.e. planning, shopping, food preparation, difficulties with finances)
- affects comprehension, but not level of consciousness

**Figure 18. Dementia classification**
Diagnosis of Major NCD requires presence of significant cognitive decline from a previous level of performance in one or more cognitive domains (complex attention, executive function, learning and memory, language, perceptual-motor, or social cognition) based on:

A) concern of the individual or a knowledgeable informant AND
B) a substantial impairment in cognitive performance either documented by standardized neuropsychological testing or quantified clinical assessment

• see Psychiatry, PS17 for DSM-5 diagnostic criteria
• see Geriatric Medicine, GM3

Differentiated from mild NCD (formerly mild cognitive impairment) by the extent to which the impairment affects ADLs

Mild NCD represents an intermediate stage between dementia and normal aging

By definition, IADLs are not affected in Mild NCD

Epidemiology

- major NCD (dementia): 1-2% at age 65 and reaching as high as 30% by age 85
- mild NCD: 2-10% at age 65 and 5-25% by age 85

Note

- Major NCD due to Alzheimer’s disease is uncommon before age 60
- Major NCD due to frontotemporal lobar degeneration has an earlier onset and represents a progressively smaller fraction of all NCDs with age

Etiology

- see Table 14 for common causes of dementia
- see Table 15 for acquired causes of dementia
- reversible causes: alcohol (intoxication or withdrawal, Wernicke's encephalopathy), medication (benzodiazepines, anticholinergics), heavy metal toxicity, hepatic or renal failure, B12 deficiency, glucose, cortisol, thyroid dysfunction, normal pressure hydrocephalus, depression (pseudodementia), intracranial tumor, subdural hematoma, hypercalcemia (secondary to elevated PTH)
- must rule out delirium

History

- “geriatric giants”
  - confusion/incontinence/falls/polypharmacy
  - memory and safety (wandering, leaving doors unlocked, leaving stove on, losing objects)
  - behavioral (mood, anxiety, psychosis, suicidal ideation, personality changes, aggression)
- ADLs and IADLs
- cardiovascular, endocrine, neoplastic, renal ROS
- alcohol, smoking
- OTCs, herbal remedies, medications (sedative hypnotics, antipsychotics, antidepressants, anticholinergics), compliance, accessibility
- history of vascular disease or head trauma
- collateral history

Physical Exam

- blood pressure
- hearing and vision
- neurological exam with attention to signs of parkinsonism, UMN findings, cerebrovascular disease
- general physical exam depending on risk factors and history
- MMSE or MoCA, clock drawing, frontal lobe testing (go/no-go, word lists, similarities, proverb)

Investigations

- depends on suspected etiologies (see Tables 13 and 14)
  - CBC (note MCV for evidence of alcohol use and B12 deficiency), glucose, TSH, B12, RBC folate
  - electrolytes, LFTs, renal function, lipids, serum calcium
  - CT head, MRI as indicated (MRI preferred), SPECT (optional)
  - as clinically indicated: VDRL, HIV, ANA, anti-dsDNA, ANCA, ceruloplasmin, copper, cortisol, toxicology, heavy metals
- issues to consider
  - failure to cope, fitness to drive, caregiver education and stress, power of attorney, legal will, advanced medical directives, patient and caregiver safety

Vitamin B12 Deficiency Symptoms

- Macrocytic anemia, pallor, SOB, fatigue, chest pain, palpitations
- Confusion or change in mental status (if advanced)
- Decreased vibration sense
- Distal numbness and paresthesia
- Weakness with UMN findings
- Diarrhea, anorexia

Vitamin D Deficiency

- Muscle weakness, fatigue, bone pain, rickets, osteomalacia, osteoporosis
- Depression, anxiety, cognitive impairment

Major or Mild NCD due to Alzheimer’s Disease

- see Psychiatry, PS17

Definition
- beyond criterion for NCD, the core features of major or mild NCD due to Alzheimer’s disease include an insidious onset and gradual progression of cognitive and behavioral symptoms
- typical presentation: amnestic (i.e. impairment in memory and learning - impaired ability to learn new information)
  - mild phase: impairment in memory and learning sometimes accompanied with deficits in executive function
  - moderate–severe phase: visuoconstructional/perceptual-motor ability and language may also be impaired
  - social cognition tends to be preserved until late in the course of the disease
• atypical nonamnestic presentation (one of the following)
  a. aphasia: language disturbance
  b. apraxia: impaired ability to carry out motor activities despite intact motor function
  c. agnosia: failure to recognize or identify objects despite intact sensory function
• note: there may be no evidence of mixed etiology (i.e. absence of other neurodegenerative or cerebrovascular disease)

Pathophysiology
• genetic factors
  - minority (<7%) of AD cases are familial (autosomal dominant)
  - 3 major genes for autosomal dominant AD have been identified
    - amyloid precursor protein (chromosome 21), presenilin 1 (chromosome 14), presenilin 2 (chromosome 1)
  - the E4 polymorphism of apolipoprotein E (APOE) is a susceptibility genotype (E2 is protective)
• note: APOE cannot serve as a diagnostic marker because it is only a risk factor and neither necessary nor sufficient for disease occurrence
• pathology (although not necessarily specific for AD)
  - gross pathology
    - diffuse cortical atrophy, especially frontal, parietal, and temporal lobes (hippocampi)
  - microscopic pathology
    - senile plaques (extracellular deposits of amyloid in the gray matter of the brain)
    - loss of synapses
    - neurofibrillary tangles (intracytoplasmic paired helical filaments with amyloid and hyperphosphorylated Tau protein)
    - loss of cholinergic neurons in nucleus basalis of Meynert that project diffusely throughout the cortex
  - biochemical pathology
    - 50-90% reduction in action of choline acetyltransferase

Epidemiology
• 1/12 of population 65-75 yr of age
• up to 1/3 population >85 yr of age
• accounts for 60-90% of all dementias (depending on setting and diagnostic criteria)

Risk Factors
• age is the largest risk factor
• genetic susceptibility polymorphism: apolipoprotein E4 increases risk and decreases age of onset
• other factors include: traumatic brain injury, family history, Down syndrome, low education, and presence of multiple vascular risk factors (e.g. smoking, HTN, hypercholesterolemia, DM)

Signs and Symptoms
• cognitive impairment
  - memory impairment for newly acquired information (early)
  - deficits in language, abstract reasoning, and executive function
• behavioral and psychiatric manifestations (80% of those with major NCD)
  - mild NCD: major depressive disorder and/or apathy
  - major NCD: psychosis, irritability, agitation, combativeness, and wandering
• motor manifestations (late)
  - gait disturbance, dysphagia, incontinence, myoclonus, and seizures
  - parkinsonism (if present consider DLB)

Investigations
• perform investigations to rule out other potentially reversible causes of dementia
• EEG: usually normal, may observe generalized slowing (nonspecific)
• MRI: preferential atrophy of the hippocampi and precuneus of the parietal lobe; dilatation of lateral ventricles; widening of cortical sulci
• SPECT: hypoperfusion in temporal and parietal lobes
• PET Imaging: imaging using Pittsburgh compound B (PIB) as a tracer enables imaging of beta-amyloid plaque in neuronal tissue

Treatment
• acetylcholinesterase inhibitors have been shown to slow decline in cognitive function
  - donepezil, rivastigmine, galantamine
• relative contraindications: bradycardia, heart block, arrhythmia, CHF, CAD, asthma, COPD, ulcers, or risk factors for ulcers, and GI bleeding
• galantamine is contraindicated in patients with hepatic/renal impairment
• memantine is an NMDA-receptor antagonist that has some benefits in later stage AD (i.e. when MMSE <17)
• symptomatic management
  1. pharmacologic
  - low dose neuroleptics for agitation (neuroleptics may worsen cognitive decline)
  - trazodone for sleep disturbance
  - antidepressants (SSRIs)
2. non-pharmacologic
   ▪ redirection
   ▪ explore inciting factors for behavior and modify behavior of patient or caregiver
   ▪ family support and day care facilities

Prognosis
   • mean duration of survival after diagnosis is approximately 10 yr, reflecting the advanced age of
     the majority of individuals rather than the course of the disease
   • in those who survive the full course, death commonly results from aspiration

Major or Mild NCD with Lewy Bodies
(formerly Dementia with Lewy Bodies)

Definition
   • A NCD that includes not only progressive cognitive impairment (with early changes in complex
     attention and executive function rather than learning and memory), but also recurrent complex
     visual hallucinations.
   • core diagnostic features
     ▪ fluctuating cognition with pronounced variations in attention and alertness
     ▪ recurrent visual hallucinations that are well formed and detailed
     ▪ spontaneous features of parkinsonism, with onset subsequent to development of cognitive
       decline (rest tremor may be absent in DLB, but otherwise same classic features of Parkinson’s
       disease)
   • suggestive/supportive features
     ▪ meets criteria for rapid eye movement (REM) sleep behavior disorder
     ▪ severe sensitivity to neuroleptic medications (rigidity, neuroleptic malignant syndrome,
       extrapyramidal symptoms)
     ▪ repeated falls, syncope, or transient episodes of unexplained loss of consciousness
     ▪ auditory or other nonvisual hallucinations, systematic delusions, and depression may also be
       present

Etiology and Pathogenesis
   • Lewy bodies (eosinophilic cytoplasmic inclusions) found in both cortical and subcortical
     structures
   • mixed DLB and AD pathology is common

Diagnostically Suggestive Markers
   • low striatal dopamine transporter uptake on SPECT or PET
   • relative preservation of medial temporal structures on CT/MRI

Epidemiology
   • 0.1-5% of the general elderly population
   • Lewy bodies are present in 20-35% of all dementia cases (more common in males)

Treatment
   • acetylcholinesterase inhibitors (e.g. donepezil)

Prognosis
   • average duration of survival 5-7 yr

Major or Mild Frontotemporal Neurocognitive Disorder
(formerly Frontotemporal Dementia)

Definition
   • refers to a group of disorders caused by progressive cell degeneration in the brain’s frontal or
     temporal lobes
   • there are several variants of FTD each with specific core symptoms
   • nevertheless, there is overlap between variants (i.e. NCD criteria along with relative sparing of
     learning and memory and perceptual-motor function)
   • common neurocognitive symptoms include deficits in executive function (e.g. poor mental
     flexibility, abstract reasoning, response inhibition, planning/organization, and increased
     distractibility)
   • “probable” is distinguished from “possible” frontotemporal NCD by:
     ▪ evidence of causative frontotemporal NCD genetic mutation, from either family history or
       genetic testing
     ▪ evidence of disproportionate frontal and/or anterior temporal atrophy on MRI or CT
     ▪ evidence of frontal and/or anterior temporal hypoperfusion or hypometabolism on PET or
       SPECT
Behavioral Variant FTD

- most common variant; disinhibition and apathy are common symptoms
- insidious onset; must show progressive deterioration of behavior and/or cognition by observation or history
- prominent decline in social cognition and/or executive abilities
- typically early symptom presentation (i.e., within the first 3 yr)
- three out of the following symptoms must be present and persistent/recurrent
  - behavioral disinhibition (socially inappropriate behavior, impulsive, careless)
  - apathy or inertia
  - loss of sympathy or empathy (diminished response to others’ needs/feelings, social interest)
  - preservative, stereotyped, or compulsive/ritualistic behavior
  - hyperorality and dietary changes (binge eating, increased consumption of alcohol/cigarettes or inedible objects)

Language Variants (Primary Progressive Aphasia)

- prominent decline in language ability, in the form of speech production, word finding, object naming, grammar, or word comprehension
- three subtypes
  - nonfluent/agrammatic variant PPA (NFAV-PPA) or progressive nonfluent aphasia (PNFA): non-fluent, labored articulation/speech, anomia, preserved single word comprehension, word-finding deficit, impaired repetition
  - semantic variant PPA (SV-PPA) or semantic dementia (SD): fluent, normal rate, anomia, impaired single word comprehension, intact repetition, use words of generalization (“thing”) or supralinear categories (“animal” for “dog”)
  - logopenic progressive aphasia (LPA): naming difficulty and impaired repetition

FTD Movement Disorders

- corticobasal degeneration (CBD): shakiness, lack of coordination, muscle rigidity and spasms
- progressive supranuclear palsy (PSP): walking and balance problems; frequent falls and muscle stiffness

Etiology and Pathogenesis

- unknown, however there is likely a genetic/familial component (40% have family history of early onset NCD)
- genetic variants: MAPT gene (Tau), PGRN gene (progranulin), VCP gene, TARDBP gene (TDP-43), CHMP2D gene
- unlike AD, FTD does not show amyloid plaques or neurofibrillary tangles, instead it is characterized by severe atrophy and specific neuronal inclusion bodies
- gross changes: atrophy in the frontal and anterior temporal lobes; cortical thinning; possible ventricular enlargement
- histological changes: gliosis, swollen neurons, microvacuolation, inclusion bodies in neurons/glia (Tau or TDP-43)

Epidemiology

- fourth most common cause of dementia (5% of all dementia cases)
- common cause of early-onset NCD in individuals younger than 65 yr

Prognosis

- median survival being 6-11 yr after symptoms onset and 3-4 yr after diagnosis
- survival is shorter and decline is faster than in typical Alzheimer’s disease

Major or Mild Vascular Neurocognitive Disorder

Definition

- diagnosis of major or mild NCD with determination of cerebrovascular disease as the dominant if not exclusive pathology that accounts for the cognitive deficits
- vascular etiology suggested by one of the following
  - onset of cognitive deficits is temporally related to one or more cerebrovascular events
  - evidence for decline is prominent in complex attention (including processing speed) and frontal-executive function
  - evidence of the presence of cerebrovascular disease from history, physical exam, and/or neuroimaging that is sufficient to account for the neurocognitive deficits
  - neuroimaging evidence of cerebrovascular disease comprises one or more of the following
    - one or more large vessel infarct or hemorrhage
    - a strategically placed single infarct or hemorrhage (e.g., angular gyrus, thalamus, basal forebrain)
    - two or more lacunar infarcts outside the brainstem
    - extensive and confluent white matter lesions
• for mild vascular NCD: history of a single stroke or extensive white matter disease is sufficient
• for major vascular NCD: history of two or more strokes, a strategically placed stroke, or a combination of white matter disease, and one or more lacune is generally necessary
• associated features supporting diagnosis: personality and mood changes, abulia, depression, emotional lability, and psychomotor slowing

Etiology and Pathogenesis
• major risk factors are the same as those for cerebrovascular disease (i.e. HTN, DM, smoking, obesity, high cholesterol levels, high homocysteine levels, other risk factors for atherosclerosis, atrial fibrillation, and conditions increasing risk of cerebral emboli)
• major or mild vascular NCD with gradual onset and slow progression is generally due to small vessel disease leading to lesions in white matter, basal ganglia, and/or thalamus
• cognitive deficits can be attributed to disruption of cortical-subcortical circuits

Epidemiology
• second most common cause of NCD
• prevalence estimates for vascular dementia/NCD range from 0.2-13% (by age 70), 16% (ages 80+) to 44.6% (ages 90+)
• higher prevalence in African Americans compared to Caucasians and East Asians
• prevalence higher in males than in females

Creutzfeldt-Jakob Disease
• rare degenerative fatal brain disorder caused by prion proteins causing spongiform changes, astrocytosis, and neuronal loss
• most common forms are sporadic (85%), hereditary (5-10%), and acquired (<1%)
• investigations: CSF analysis, MRI brain (cortical and/or subcortical FLAIR changes), EEG (periodic complexes)
• definitive diagnosis is by brain biopsy
• no treatments currently exist

Normal Pressure Hydrocephalus
• see Neurosurgery, NS7

Aphasia
Definition
• an acquired disturbance of language characterized by errors in speech production, writing, comprehension, or reading

Neuroanatomy of Aphasia
• Broca's area (posterior inferior frontal lobe) involved in speech production (expressive)
• Wernicke's area (posterior superior temporal lobe) involved in comprehension of language (receptive)
• angular gyrus is responsible for relaying written visual stimuli to Wernicke's area for reading comprehension
• arcuate fasciculus association bundle connects Wernicke's and Broca's areas

Assessment of Language
• assessment of context
  ▪ handedness (writing, drawing, toothbrush, scissors), education level, native language, learning difficulties
• assessment of aphasia
  ▪ spontaneous speech (fluency, paraphasias, repetition, naming, comprehension – auditory and reading, writing, neologisms)
**Apraxia**

**Definition**
- Inability to perform skilled voluntary motor sequences that cannot be accounted for by weakness, ataxia, sensory loss, impaired comprehension, or inattention

**Clinicopathological Correlations**

**Table 16. Apraxia**

<table>
<thead>
<tr>
<th>Description</th>
<th>Tests</th>

**Mild Traumatic Brain Injury**

**Definition**
- mild TBI = concussion
- trauma induced transient alteration in mental status that may involve loss of consciousness
- hallmarks of concussion: confusion and amnesia, which may occur within minutes
- loss of consciousness (if present) must be less than 30 min, initial GCS must be between 13-15, and post-traumatic amnesia must be less than 24 h

**Epidemiology**
- 75% of TBIs are estimated to be mild; remainder are moderate or severe (see Neurosurgery, NS31 and Emergency Medicine, ER7)
- highest rates in children 0-4 yr, adolescents 15-19 yr, and elderly >65 yr

**Clinical Features**
- impairments following mild TBI
  - somatic: headache, sleep disturbance, N/V, blurred vision
  - cognitive dysfunction: attentional impairment, reduced processing speed, drowsiness, amnesia
  - emotion and behavior: impulsivity, irritability, depression
- severe concussion: may precipitate seizure, bradycardia, hypotension, sluggish pupils
- associated conditions: brain contusion, diffuse axonal injury, C-spine injury

**Investigations**
- neuro exam to identify focal neurologic deficits
- neurocognitive assessment
  - simple orientation questions are inadequate to detect cognitive changes
  - initial assessment of severity is determined by
    - Glasgow Coma Scale: mild: 13-15, moderate: 9-12, severe: 3-8
    - sideline evaluation: Standardized Assessment of Concussion, Westmead Post-Traumatic Amnesia Scale, Sport Concussion Assessment Tool
- neuroimaging
  - x-ray of skull: not indicated for routine evaluation of MTBI
  - CT head as indicated (see Emergency Medicine, ER8)
  - MRI not indicated in initial evaluation – indicated in presence of continued or worsening symptoms despite normal CT

**Treatment**
- observation for first 24 h after mild TBI in all patients because of risk of intracranial complications
- emergency department for assessment if any loss of consciousness or persistent symptoms
- hospitalization with normal CT if GCS <15, seizures, or bleeding diathesis; or abnormal CT scan
- early rehabilitation to maximize outcomes
  - OT, PT, SLP, vestibular therapy, driving, therapeutic recreation
- pharmacological management of headaches, pain, depression
- CBT, relaxation therapy
- follow Return to Play guidelines (www.thinkfirst.ca)

**Prognosis**
- most recover from mild TBI with minimal treatment, but some experience long-term consequences
- athletes with a previous concussion are at increased risk of subsequent concussion and cumulative brain injury
- repeat TBI can lead to life threatening cerebral edema (controversially known as second impact syndrome) or permanent impairment
- sequelae include
  - postconcussion syndrome: dizziness, headache, neuropsychiatric symptoms, cognitive impairment (usually resolves within weeks to months)
  - post-traumatic headaches: begin within seven days of injury
  - post-traumatic epilepsy: twofold increase in risk of epilepsy in 5 yr post-TBI, prophylactic anticonvulsants not effective
  - post-traumatic vertigo

**Extent of retrograde amnesia correlates with severity of injury**
- Required from most distant to recent memories

Movement Disorders

Overview of Movement Disorders

Table 18. Movement Disorder Definitions

<table>
<thead>
<tr>
<th>Disorder</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Akathisia</td>
<td>Subjective restlessness relieved by stereotypic movements (e.g. squirming)</td>
</tr>
<tr>
<td>Asterix</td>
<td>Loss of muscle contraction (negative myoclonus)</td>
</tr>
<tr>
<td>Athetosis</td>
<td>Slow writhing movements, especially distally</td>
</tr>
<tr>
<td>Bradykinesia</td>
<td>Slow and/or small amplitude movements</td>
</tr>
<tr>
<td>Chorea</td>
<td>Brief, abrupt, irregular movements; can appear purposeful in milder forms</td>
</tr>
<tr>
<td>Dyskinesia</td>
<td>Any sudden involuntary movement, but the term is often used to describe the stereotypical movements that come with long-term neuroleptic or dopaminergic use</td>
</tr>
<tr>
<td>Dystonia</td>
<td>Co-contraction of agonist and antagonists causing sustained twisting movements</td>
</tr>
<tr>
<td>Freezing</td>
<td>Episodes of halted motor action, especially during walking</td>
</tr>
<tr>
<td>Hemiballismus</td>
<td>Unilateral violent flinging movement</td>
</tr>
<tr>
<td>Myoclonus</td>
<td>Brief muscle group contraction that is either focal, segmental, or generalized</td>
</tr>
<tr>
<td>Myokimia</td>
<td>Spontaneous, fine, fascicular contraction of muscle</td>
</tr>
<tr>
<td>Tachykiniesia</td>
<td>Acceleration of movements</td>
</tr>
<tr>
<td>Tics</td>
<td>Stereotyped repetitive actions due to inner urge; can be suppressed</td>
</tr>
<tr>
<td>Tremor</td>
<td>Rhythmic alternating muscle contraction and relaxation</td>
</tr>
</tbody>
</table>

Function of the Basal Ganglia

• the cerebral cortex initiates movement via excitatory (glutamatergic) projections to the striatum, which then activate two pathways: direct and indirect
  • direct: cortex \( \rightarrow \) striatum \( \rightarrow \) GPi/SNr \( \rightarrow \) thalamus \( \rightarrow \) motor cortex
    - activation of this pathway removes the inhibitory effect of the GPi on the thalamus, letting the thalamus activate the cortex and ultimately allowing movement
  • indirect: cortex \( \rightarrow \) striatum \( \rightarrow \) GPe \( \rightarrow \) STN \( \rightarrow \) GPi/SNr \( \rightarrow \) thalamus \( \rightarrow \) motor cortex
    - activation of this pathway causes inhibition of the thalamus and ultimately prevents movement

Hemiballismus is most often due to a vascular lesion of the contralateral subthalamic nucleus

Some myoclonus is stimulus sensitive and can be induced by noise, movement, light, visual threat, or pinprick

In some cases, dystonias may only occur during voluntary movement and sometimes only during specific activities such as writing, chewing, or speaking
Differential Diagnoses

1. Tremor
   - **postural**: physiologic, anxiety, sedative/alcohol withdrawal, drug toxicity, heavy metal poisoning, carbon monoxide poisoning, thyrotoxicosis, benign essential tremor, cerebellar, Wilson's disease
     - benign essential tremor is a common autosomal dominant trait that presents as a bilateral postural tremor of the vertical axis, especially in the upper extremities
   - **intention**: brainstem lesion, cerebellar lesion, alcohol, anticonvulsants, sedatives, Wilson's disease
   - **resting**: Parkinsonism, Wilson's disease, mercury poisoning

In a young patient (<45) must do TSH (thyroid disease), ceruloplasmin (Wilson's disease), and CT/MRI (cerebellar disease) as indicated by type of tremor

Alcohol
- Dampens essential tremor
- Potentiates intention tremor
- Does not improve resting tremor of PD

>90% of essential tremor does not need treatment
Table 19. Approach to Tremors

</table>

2. Chorea: Huntington’s disease, neuroacanthocytosis, SLE, APLA syndrome, Wilson’s disease, cerebrovascular disease, tardive dyskinesia, senile chorea, Sydenham’s chorea, pregnancy chorea

3. Dystonia
   • primary dystonia: familial, sporadic (torticollis, blepharospasm, writer’s cramp)
   • dystonia-plus syndromes: dopa-responsive dystonia, myoclonus-dystonia
   • secondary dystonia: thalamotomy, stroke, CNS tumor, demyelination, PNS injury, drugs/toxins (L-dopa, neuroleptics, anticonvulsants, Mn, CO, cyanide, methanol)
   • heterodegenerative dystonias: Parkinsonian disorders, Wilson’s disease, Huntington’s disease

4. Myoclonus
   • physiologic myoclonus: hiccups, nocturnal myoclonus
   • essential myoclonus
   • epileptic myoclonus
   • symptomatic myoclonus
     ▪ degenerative disorders (Wilson’s disease, Huntington’s disease, Corticobasal degeneration)
     ▪ infectious disorders (CJD, viral encephalitis, AIDS-dementia complex)
     ▪ metabolic disorders (drug intoxication/withdrawal, hypoglycemia, hyponatremia, HONK, hepatic encephalopathy, uremia, hypoxia)
     ▪ focal brain damage (head injury, stroke, mass)

5. Tics
   • primary tic disorders: transient tic disorder, chronic tic disorder, Gilles de la Tourette, adult onset or senile
   • secondary tic disorders: encephalitis, CJD, Sydenham’s chorea, head trauma, drugs, mental retardation syndromes
   • association with OCD and ADHD

**Parkinson’s Disease**

**Etiology**
   • sporadic: combination of oxidative stress to dopaminergic neurons, environmental toxins (e.g. pesticides), accelerated aging, genetics
   • familial (10%): autosomal dominant α-synuclein mutations, autosomal recessive Parkin gene or DJ-1 gene mutation (juvenile onset)
   • MPTP (neurotoxin)

**Epidemiology**
   • prevalence of 0.3% in industrialized countries, but rises with increased age
   • second most common neuro-degenerative disorder, after Alzheimer’s
   • mean age of onset is 60 yr

**Risk Factors**
   • family history, male, head injury, rural living, exposure to certain neurotoxins
   • protective: coffee drinking, smoking, NSAID use, estrogen replacement in post-menopausal women

**Pathophysiology**
   • loss of dopaminergic neurons in pars compacta of substantia nigra, thus reduced dopamine in striatum leading to disinhibition of the indirect pathway and decreased activation of the direct pathway causing increased inhibition of cortical motor areas
   • α-synucleinopathy: α-synuclein accumulates in Lewy bodies and causes neurotoxicity in substantia nigra
Signs and Symptoms
- positive motor
  - resting tremor: asymmetric 4-5 Hz “pill-rolling” tremor, especially in hands
  - rigidity: lead-pipe rigidity with cogwheeling due to superimposed tremor
- negative motor
  - bradykinesia: slow, small amplitude movements, fatiguing of rapid alternating movements, difficulty initiating movement
- related findings: masked facies, hypophonia, aprosody (monotonous speech), dysarthria, micrographia, shuffling gait with decreased arm swing
- freezing: occurs with walking triggered by initiating stride or barriers/destinations, lasting seconds
- postural instability: late finding presenting as falls, festinating gait
- cognition: bradyphrenia (slow to think/respond), dementia (late finding)
- behavioral: decreased spontaneous speech, depression, sleep disturbances, anxiety
- autonomic: constipation, urinary retention, sexual dysfunction, later findings of orthostatic hypotension

Treatment
- pharmacologic
  - mainstay of treatment: Sinemet® (levodopa/carbidopa). Levodopa is a dopamine precursor; carbidopa decreases peripheral metabolism of levodopa, decreasing side effects and increasing half-life of levodopa
  - levodopa-related fluctuation: delayed onset of response (affected by mealtime), end-of-dose deterioration (“wearing-off”), random oscillations of on-off symptoms
  - major complication of levodopa is dyskinesia
  - treatment of early PD: dopamine agonists, amantadine, MAOI
  - adjuncts: dopamine agonists, MAOI, anticholinergics (especially if prominent tremors), COMT inhibitors
- surgical: thalamotomy, pallidotomy, deep brain stimulation (thalamic, pallidal, subthalamic)
- psychiatric (see Psychiatry, PS18)

Other Parkinsonian Disorders
- Dementia/NCD with Lewy bodies (DLB) (see Behavioral Neurology, N23)
- Progressive supranuclear palsy (PSP): tauopathy with limited vertical gaze (classically downgaze), early falls, axial rigidity and akinesia, dysarthria, and dysphagia
- Corticobasal degeneration (CBD): tauopathy with varied presentations but classically presents with unilateral parkinsonism, dystonia/myoclonus, apraxia ± “alien limbs” phenomenon; may also present as progressive non-fluent aphasia
- Multiple system atrophy (MSA): synucleinopathy presenting as either cerebellar predominant (previously olivo-ponto cerebellar atrophy or OPCA) or parkinsonism predominant (previously striato-nigral degeneration); both are associated with early autonomic dysfunction (previously Shy-Drager syndrome)
- Huntington’s disease: multi-infarct presentation with lower body parkinsonism

Huntington’s Disease

Etiology and Pathogenesis
- genetics: autosomal dominant CAG repeats (with anticipation) in Huntington gene on Chromosome 4, which leads to accumulation of defective protein in neurons
- pathology: global cerebral atrophy, especially affecting the striatum, leading to increased activity of the direct pathway and decreased activity of the indirect pathway

Epidemiology
- North American prevalence 4-8/100,000
- mean age of onset 35-44 yr; but varies with degree of anticipation from 5-70 yr

Signs and Symptoms
- typical progression: insidious onset with clumsiness, fidgetiness, and irritability, progressing over 15 yr to frank dementia, psychosis, and chorea
- dementia: progressive memory impairment and loss of intellectual capacity
- chorea: begins as movement of eyebrows and forehead, shrugging of shoulders, and parakinesia (pseudopurposeful movement to mask involuntary limb jerking)
- progresses to dance-like or ballism, and in late stage is replaced by dystonia and rigidity
- mood changes: irritability, depression, anhedonia, impulsivity, bouts of violence

Consider an Alternative Diagnosis if Atypical Parkinsonism
- Poor response to levodopa
- Abrupt onset of symptoms
- Rapid progression
- Early falls
- Early autonomic dysfunction
- Symmetric symptoms at onset
- Early age of onset (<50 yr)
- Early cognitive impairment
- Fx of psychiatric/dementing disorders
- Recent diagnosis of psychiatric disease
- History of encephalitis
- Unusual toxin exposure
- Extensive travel history

Dopamine Agonist Therapy in Early Parkinson’s Disease
Cochrane DB Syst Rev 2009;2:CD006564
Study: Meta-analysis of trials of dopamine agonists in early Parkinson’s disease.
Results: Twenty-nine trials were included (n=5,247). Dopamine agonists were found to have decreased motor side effects (dyskinesia OR 0.51), dystonia OR 0.64), motor fluctuations (OR 0.70) compared to levodopa, but provided poorer symptom control compared to levodopa. Also, other side effects were increased (constipation OR 1.51, hallucinations OR 1.69, dizziness OR 1.45).
Conclusion: Dopamine agonists have fewer motor side effects than levodopa, but provide worse symptom control and increased rate of other side effects.

Juvenile Onset (Westphal Variant)
Begin in adolescence with bradykinesia and rigidity with a severe progressive course spanning 5-10 yr

Extensive travel history
Investigations
- MRI: enlarged ventricles, atrophy of cerebral cortex and caudate nucleus
- genetic testing
  - expansion of the cytosine-adenine-guanine (CAG) trinucleotide repeats in the HTT gene
  - CAG repeats on chromosome 4p16.3 that encodes the protein huntingtin

Treatment
- no disease altering treatment
- psychiatric symptoms: antidepressants and antipsychotics
- chorea: neuroleptics and benzodiazepines
- dystonia: botulinum toxin

Dystonia

Epidemiology
- third most common movement disorder after Parkinson's disease and essential tremor

Clinical Features
- symptoms exacerbated by fatigue, stress, emotions; relieved by sleep or specific tactile/proprioceptive stimuli (‘geste antagoniste’, e.g. place hand on face for cervical dystonia)
- more likely to be progressive and generalize if younger onset or leg dystonia

Treatment
- local medical: botulinum toxin
- systemic medical: anticholinergics (benztropine), muscle relaxants (baclofen), benzodiazepines, antidopaminergics (reserpine, neuroleptics); dopamine for dopa-responsive dystonia
- surgical: surgical denervation of affected muscle, stereotaxic thalamotomy (unilateral dystonia), posteroventral pallidotomy

Tic Disorders

Definition
- a tic is a sudden, rapid, recurrent, nonrhythmic, stereotyped motor movement or vocalization
- common criteria
  - tics may wax and wane in frequency but have persisted for an extended period of time
  - onset before age 18 yr
  - disturbance is not attributable to the physiological effects of a substance or another medical condition

Clinical Classification
- Tourette's disorder: multiple motor and one or more vocal tics that have persisted for more than 1 yr since onset
- Persistent (chronic) motor or vocal tic disorder: single or multiple motor or vocal tics (but not both motor and vocal) that have persisted for more than 1 yr since onset
- Provisional tic disorder: single or multiple motor and/or vocal tics present for <1 yr since first tic onset
- other specified or unspecified tic disorder: symptoms characteristic of a tic disorder but do not meet full criteria

Motor vs. Vocal Tics
- simple tics tend to be of short duration (milliseconds)
- complex tics tend to be longer (seconds) and often include a combination of simple tics
  - complex tics may often appear to be purposeful
- motor tics
  - simple: blinking, head jerking, shoulder shrugging, extension of the extremities
  - dystonic: bruxism, grinding teeth, abdominal tension, sustained mouth opening
- complex: copropraxia (obscene gestures), echopraxia (imitate gestures), throwing, touching
- vocal tics
  - simple: blowing, coughing, grunting, throat clearing
  - complex: coprolalia (shout obscenities), echolalia (repeat others’ phrases), palilalia (repeat own phrases)

Treatment
- dopamine blocker
Tourette’s Syndrome (Gilles de la Tourette’s Syndrome)

Definition According to DSM 5
1. presence of both multiple motor and one or more vocal tics at some point during the illness, although not necessarily concurrently
2. tics may wax and wane in frequency but have persisted for more than 1 yr since first tic onset (with no tic-free periods greater than 3 mo)
3. onset is before age 18 yr
4. not due to effect of a substance or another medical condition

Epidemiology
• estimated prevalence among adolescents 3-8 per 1,000 school-age children; M:F = 2:1 to 4:1

Signs and Symptoms
• tics: wide variety that wax and wane in type and severity; can be voluntarily suppressed for some time but are preceded by unpleasant sensation that is relieved once tic is carried out
  - can be worsened by anxiety, excitement, and exhaustion; better during calm focused activities
• psychiatric: compulsive behaviors (associated with OCD and ADHHD), hyperactive behavior, rages, sleep-wake disturbances, learning disabilities

Treatment
• clonidine, clonazepam

Prognosis
• typically begins between ages 4-6
• peak severity occurs between ages 10-12, with a decline in severity during adolescence (50% are tic-free by 18 yr of age)
• tic symptoms however can manifest similarly in all age groups and across the lifespan

Cerebellar Disorders

Clinico-Anatomic Correlations
• vermis: trunk/gait ataxia
• cerebellar lobe (i.e. lateral): rebound phenomenon, scanning dysarthria, dysdiadochokinesis, dysmetria, nystagmus

Symptoms and Signs of Cerebellar Dysfunction
• nystagmus: observe during extraocular movement testing (most common is gaze-evoked nystagmus)
• dysarthria (ataxic): abnormal modulation of speech velocity and volume – elicit scanning/telegraphic/slurred speech on spontaneous speech (see CN X Vagus Nerve, N11)
• ataxia: broad-based, uncoordinated, lurching gait
• dysmetria: irregular placement of voluntary limb or ocular movement
• dysdiadochokinesis: impairment of rapid alternating movements (e.g. pronation – supination task)
• postural instability: truncal ataxia on sitting, titubation (rhythmic rocking of trunk and head), difficulty with tandem and broad-based gait
• intention tremor: typically orthogonal to intended movement, and increases as target is approached
• hypotonia: decreased resistance to passive muscular extension (occurs shortly after injury to lateral cerebellum)
• pendular patellar reflex: knee reflex causes pendular motion of leg (occurs after injury to cerebellar hemispheres)
• rebound phenomenon: overcorrection after displacement of a limb
• hypometric and hypermetric saccades
  - pendular reflexes at triceps

Wernicke-Korsakoff Syndrome

• see Psychiatry, PS23
• note that alcohol can also cause a cerebellar ataxia separate from thiamine deficiency; this ataxia can be due to cerebellar atrophy or alcohol polyneuropathy
Cerebellar Ataxias

Congenital Ataxias
- early onset nonprogressive ataxias associated with various syndromes as well as developmental abnormalities (e.g. Arnold-Chiari malformation, Dandy-Walker cysts)

Hereditary Ataxias
- autosomal recessive: includes Friedrich's ataxia, ataxia telangiectasia, vitamin E deficiency
  - Friedrich's ataxia: prevalence 2/100,000; onset between 8 and 15 yr
    - signs: gait and limb ataxia, weakness, areflexia, extensor plantar reflex, impaired proprioception and vibration, dysarthria
    - death in 10-20 yr from cardiomyopathy or kyphoscoliotic pulmonary restriction
- autosomal dominant: most commonly spinocerebellar ataxias (30 types, most due to CAG repeats)
  - signs: ataxia and dysarthria; ± myoclonus, chorea, polyneuropathy, pyramidal or extrapyramidal features, hyporeflexia, seizures, dementia

Acquired Ataxias
- neurodegeneration (e.g. multiple system atrophy)
- systemic: alcohol, celiac sprue, hypothyroidism, Wilson’s, thiamine deficiency
- toxins: carbon monoxide, heavy metals, lithium, anticonvulsants, solvents
- vascular: infarct, bleed, basilar migraine
- autoimmune: MS, Miller-Fischer (GBS)

Vertigo
- see Otolaryngology, OT12

Gait Disturbances

Approach to Gait Disturbances
1. Characterization of the gait disturbance
   - posture, stride length, width between feet, height of step, stability of pelvis, symmetry, arm swing, elevate/inconsistent movements, standing from sitting
2. Identification of accompanying neurologic signs
   - full neurological exam required (diagnosis often can be made by P/E alone)
3. Identify red flags
   - sudden onset, cerebellar ataxia, paresis (hemi, para, or quadra), bowel/bladder incontinence
4. Workup
   - based on etiology – requires blood work, neuroimaging, and urgent neurologist referral

Table 20. Types of Gait Disturbance

Motor Neuron Disease

Amyotrophic Lateral Sclerosis (Lou Gehrig’s Disease)

**Definition**
- progressive neurodegenerative disease that causes UMN and LMN symptoms and is ultimately fatal

**Etiology**
- idiopathic (most), genetic (5-10% familial, especially SOD1 mutation, other: C9orf72, TARDBP)

**Pathology**
- disorder of anterior horn cells of spinal cord, cranial nerve nuclei, and corticospinal tract

**Epidemiology**
- 5/100,000; incidence increases with age

**Signs and Symptoms**
- limb motor symptoms: segmental and asymmetrical UMN and LMN symptoms
- bulbar findings: dysarthria (flaccid or spastic), dysphagia, tongue atrophy and fasciculations, facial weakness and atrophy
- pseudobulbar affect, frontotemporal dementia (up to 10%)
- sparing of sensation, ocular muscles, and sphincters

**Investigations**
- EMG: chronic denervation and reinnervation, fasciculations
- NCS: to rule out peripheral neuropathy (i.e. multifocal motor neuropathy with conduction block)
- CT/MRI: to rule out cord disease/compression

**Management**
- riluzole (modestly slows disease progression)
- symptomatic relief
  - spasticity/cramping: baclofen, tizanidine, regular exercise, and physical therapy
  - sialorrhea: TCA (i.e. amitriptyline), sublingual atropine drops, parotid/submandibular botox (rare)
  - pseudobulbar affect: dextromethorphan/quinidine, TCA, SSRI
- non-pharmacologic: high caloric diet, ventilatory support (especially BiPAP), early nutritional support (i.e. PEG tube), rehabilitation (PT, OT, SLP), psychosocial support

**Prognosis**
- median survival 3 yr; death due to respiratory failure

Other Motor Neuron Diseases

- degenerative
  - progressive muscular atrophy (progressive bulbar palsy): only LMN symptoms with asymmetric weakness, later onset than ALS, 5-10% of patients in ALS centers
  - primary lateral sclerosis (progressive pseudobulbar palsy): UMN symptoms, later onset, not fatal with variable disability; 5-10% of patients in ALS centers
  - spinal muscular atrophy: pediatric disease with symmetric LMN symptoms
- infectious
  - post-polio syndrome: residual asymmetric muscle weakness, atrophy
- acquired
  - multifocal motor neuropathy: conduction block on NCS, asymmetric LMN symptoms, ± anti-GM1 Ab, treatable with IVIg

Peripheral Neuropathies

**Diagnostic Approach to Peripheral Neuropathies**
1. Differentiate: motor vs. sensory vs. autonomic vs. mixed
2. Pattern of deficit: symmetry; focal vs. diffuse; upper vs. lower limb; cranial nerve involvement
3. Temporal pattern: acute vs. chronic; relapsing/remitting vs. constant vs. progressive
4. History: PMH, detailed FHx, exposures (e.g. insects, toxins, sexual, travel), systemic symptoms
5. Detailed peripheral neuro exam: LMN findings, differentiate between root and peripheral nerves, cranial nerves, respiratory status
Classification
- monoradiculopathy: dermatomal deficit due to single nerve root lesion
  - due to disc herniation or root compression causing radicular pain
  - little tactile anesthesia, as dermatomes overlap
- polyradiculopathy: multiple dermatome deficits due to multiple nerve root lesions
  - one type is cauda equina syndrome (lumbosacral roots)
- plexopathy: deficit matching distribution of a nerve plexus
  - brachial plexopathy
    - upper (C5-C7): LMN sx of shoulder and upper arm muscles (Erb’s palsy)
    - lower (C8-T1): LMN sx and sensory sx of forearm and hand (Klumpke's palsy)
    - DDx: trauma, idiopathic neuritis, tumor infiltration, radiation, thoracic outlet syndrome (i.e. cervical rib)
  - lumbosacral plexopathy (rare, especially unilateral)
    - DDx: idiopathic neuritis, infarction (i.e. DM), compression
- mononeuropathy: single nerve deficit
  - carpal tunnel syndrome (most common): compression of median nerve at wrist
    - symptoms: wrist pain, paresthesia first 3 and ½ digits, ± radiation to elbow, worse at night
    - signs: Tinel’s sign, Phalen’s test, thenar muscle wasting, sensory deficit
    - EMG and NCS: slowing at wrist (both motor and sensory)
    - etiology: entrapment, pregnancy, DM, gangliopathy, rheumatoid arthritis, thyroid disease
    - Bell's palsy (most common cranial neuropathy): see Otolaryngology, OT23
  - other less common mononeuropathies due to entrapment/compression: ulnar (compression at elbow), median (at pronator teres), radial (at spiral groove of humerus), obturator (from childbirth), peroneal (due to crossing legs or surgical positioning), posterior tibial (tarsal canal)
- mononeuropathy multiplex: deficit affecting multiple discrete nerves (asymmetric)
  - must rule out vasculitis or collagen vascular disease
- polyneuropathy: symmetrical distal stocking-glove pattern
  - symmetrical distal sensorimotor deficit affecting longest fibers first (stocking-glove distribution), hypesthesia; progression of dysesthesia early and weakness later
  - etiology: DM (most common), renal disease, substances, toxins, genetics, SLE, HIV, leprosy, alcohol, B12 deficiency, uremia
- chronic inflammatory demyelinating polyneuropathy (CIDP)
  - chronic relapsing sensorimotor polyneuropathy with increase protein in CSF and demyelination (shown on EMG/NCS)
  - course is fluctuating, in contrast with the acute onset of GBS
  - treatment: first-line is prednisone; alternatives are plasmapheresis, IVIg, and azathioprine

Table 21. Differential Diagnosis of Symmetric Polyneuropathy

A = autonomic; CIDP = chronic inflammatory demyelinating polyradiculoneuropathy; GGT = gamma-glutamyl transferase; HMSN = hereditary motor sensory neuropathy; M = motor; GBS = Guillain-Barré syndrome; PAN = polyarteritis nodosa; RA = rheumatoid arthritis; S = sensory; SLE = systemic lupus erythematosus; SPED = serum protein electrophoresis.

Tinel’s Sign: Tap lightly over the median nerve at the wrist; the patient’s symptoms of carpal tunnel will be elicited in a positive test.

Phalen’s Test: Hold both wrists in forced flexion (with the dorsal surfaces of the hands pressed against each other) for 30-60 s; test is positive if symptoms of carpal tunnel are elicited.

Diabetic Neuropathies
- Peripheral neuropathy; pain or loss of sensation in a glove and stocking distribution (hands and feet affected before arms and legs)
- Autonomic: anhidrosis, orthostatic hypotension, impotence, gastroparesis, bowel and bladder dysfunction
- Mononeuropathy multiplex: nerve infarct or compression
- Cranial neuropathy: CN III (pupil sparing) > IV > VI
- Lumbosacral plexopathy

CMT1A duplication/deletion and Cx32 mutations.
Guillain-Barré Syndrome
- definition: acute rapidly evolving demyelinating inflammatory polyneuropathy that often starts in the distal lower limbs and ascends
- etiology
  - autoimmune attack and damage to peripheral nerve myelin
  - sometimes preceded by viral/bacterial infections
- signs and symptoms
  - sensory: distal and symmetric paresthesias, loss of proprioception and vibration sense, neuropathic pain
  - motor: weakness starting distally in legs, areflexia
  - autonomic: blood pressure dysregulation, arrhythmias, bladder dysfunction
- investigations
  - CSF: albuminocytological dissociation (high protein, normal WBC)
  - EMG/NCS: conduction block, differential or focal (motor > sensory) slowing, decreased F-wave, sural sparing
- subtypes
  1. acute inflammatory demyelinating polyneuropathy (AIDP)
  2. acute motor-sensory axonal neuropathy (AMSAN)
  3. acute motor axonal neuropathy (AMAN)
- treatment
  - IVIg or plasmapheresis, ± pain management, monitor vitals and vital capacity
- prognosis
  - peak of symptoms at 2-3 wk, resolution at 4-6 wk
  - 5% mortality (higher if require ICU); up to 15% have permanent deficits

Myasthenia Gravis

Etiology and Pathophysiology
- progressive autoimmune disorder due to anti-AChR antibodies, resulting in early saturation at the NMJ and inadequate muscle activation with increasing nerve stimulation
- 15% of patients with MG have associated thymic neoplasia, 85% have thymic hyperplasia

Epidemiology
- bimodal age of onset – 20s (mostly women) and 60s (mostly men)

Signs and Symptoms
- see Table 22
- fatiguable, symmetric or asymmetric weakness without reflex changes, sensory changes, or coordination abnormalities
- ocular (diplopia/ptosis), bulbar (dysarthria/dysphagia), and/or proximal limb weakness
- symptoms may be exacerbated by infection, pregnancy, menses, and various drugs
- respiratory muscle weakness may lead to respiratory failure

GBS is a neurological emergency due to risk of imminent respiratory failure

The most common antecedent infection in GBS is Campylobacter jejuni

Miller-Fisher Variant of GBS – Triad
- Ophthalmoplegia
- Ataxia
- Areflexia

IVIg and plasmapheresis lead to more rapid improvement, less intensive care and less ventilation, but do not change mortality or relapse rate

Diseases of the neuromuscular junction typically feature prominent fatiguability
- Fatiguability can be tested by holding the arms out or by holding the gaze in the upward position (especially in MG)
- Muscle weakness due to fatiguability will improve with rest or ice

Myasthenia gravis
**Investigations**
- edrophonium (Tensilon®) test
  - assess for improvement over 2 min following edrophonium injection
- EMG
  - repetitive stimulation → decremental response
  - single fiber electromyography shows increased jitter (80-100% sensitivity)
- spirometry – forced vital capacity may be used to monitor adequacy of respiratory effort over time
- anti-acetylcholine receptor antibody assay (70-80% sensitivity)
- MUSK antibody may be used if seronegative for AChR antibody
- CT/MRI to screen for thymoma/thymic hyperplasia

**Treatment**
- thymectomy
  - 85% of patients show improvement or remission
- symptomatic relief
  - acetylcholinesterase inhibitors (e.g. pyridostigmine)
    - does not affect primary pathologic process so rarely results in control of disease when used alone
- immunosuppression
  - steroids are mainstay of treatment (70-80% remission rate)
  - azathioprine, cyclophosphamide, and mycophenolate as adjuncts or as steroid sparing therapy
- short-term immunomodulation (for crises)
  - IVIg and plasmapheresis

**Prognosis**
- 30% eventual spontaneous remission
- with treatment, life expectancy is equal to that of a person without MG, but quality of life may vary

---

**Lambert-Eaton Myasthenic Syndrome**

**Etiology and Pathophysiology**
- autoimmune disorder due to antibodies against presynaptic voltage-gated calcium channels, causing decreased ACh release at the NMJ
- 50-66% are associated with small cell carcinoma of the lung

**Signs and Symptoms**
- see Table 22
- weakness of skeletal muscles without sensory or coordination abnormalities
- reflexes are diminished or absent, but increase after active muscle contraction
- bulbar and ocular muscles affected
- prominent anticholinergic autonomic symptoms (dry mouth > impotence > constipation > blurred vision)

**Investigations**
- edrophonium test (see Myasthenia Gravis, N37) → no response
- EMG
  - rapid (>10 Hz) repetitive stimulation → incremental response
  - post-exercise facilitation → an incremental response with exercise
  - screen for malignancy, especially small cell lung cancer

**Treatment**
- tumor removal
- acetylcholine modulation
  - increased acetylcholine release (3,4-diaminopyridine)
  - decreased acetylcholine degradation (pyridostigmine)
- immunomodulation
  - steroids, plasmapheresis, IVIg

---

**Botulism**

**Etiology and Pathophysiology**
- caused by a toxin produced by spores of *Clostridium botulinum* bacteria, which is found in soil and water throughout the world
- bacteria can enter the body through wounds or by ingesting improperly preserved foods
- infantile botulism is the most common form, and is usually from ingestion of honey or corn syrup

**Signs and Symptoms**
- occur 6-48 h after ingestion
- difficulty with convergence, ptosis, paralysis of extraocular muscles
- dilated, poorly reactive pupils
• other autonomic dysfunction: jaw weakness, dysarthria, dysphagia
• spreads to trunk and limbs
  ▪ abdominal cramps with N/V
  ▪ symmetric weakness with paralysis and absent/decreased deep tendon reflexes
  ▪ anticholinergic symptoms: dry mouth, constipation, urinary retention
• rarely respiratory distress, potentially advancing to respiratory failure
  ▪ pattern of paresis often starts with GI symptoms (constipation, early satiety), then paresis of extracocular muscles, then dysphagia, then limbs/respiratory involvement; all associated with dry mouth

Investigations
• blood test for toxin
• stool culture

Treatment
• botulinum anti-toxin – good prognosis with prompt treatment
• supportive therapy as required

MELAS = mitochondrial encephalomyopathy, lactic acidosis, and stroke-like episodes; MERRF = mitochondrial encephalomyopathy with ragged red fibers
**Polymyositis/Dermatomyositis**

- see Rheumatology, RH15

**Myotonic Dystrophy**

**Etiology and Pathophysiology**
- unstable trinucleotide (CTG) repeat in DMK gene (protein kinase) at 19q13.3, number of repeats correlates with severity of symptoms
- autosomal dominant

**Epidemiology**
- most common adult muscular dystrophy
- prevalence 3-5/100,000

**Signs and Symptoms**
- appearance: ptosis, bifacial weakness, frontal baldness (including women), triangular face giving a drooping/dull appearance
- physical exam
  - distribution of weakness: distal weaker than proximal (in contrast to other myopathies), steppage gait
  - myotonia: delayed relaxation of muscles after exertion (elicit by tapping on thenar muscles with hammer)
  - cardiac: 90% have conduction defects (1st heart block; atrial arrhythmias)
  - respiratory: hypoventilation 2nd to muscle weakness
  - ocular: subcapsular cataracts, retinal degeneration, decreased intraocular pressure
  - other: DM, infertility, testicular atrophy
- EMG: subclinical myotonia – long runs with declining frequency and amplitude

**Treatment and Prognosis**
- no cure, progressive, death usually around 50 yr
- management of myotonia: phenytoin

**Duchenne and Becker Muscular Dystrophy**

- see Pediatrics, P45

**Pain Syndromes**

**Approach to Pain Syndromes**

**Definitions**
- nociceptive pain: pain arising from normal activation of peripheral nociceptors
- neuropathic pain: pain arising from direct injury to neural tissue, bypassing nociceptive pathways
- spontaneous pain: unprovoked burning, shooting, or lancinating pain
- paresthesiae: spontaneous abnormal nonpainful sensations (e.g. tingling)
- dysesthesiae: evoked pain with inappropriate quality or excessive quantity
- allodynia: a dyesthetic response to a non-noxious stimulus
- hyperalgesia: an exaggerated pain response to a noxious stimulus

**Non-Pharmacological Management**
- physical (PT, acupuncture, chiropractic manipulation, massage)
- psychoeducational (CBT, family therapy, education, psychotherapy)

**Medical Pain Control**
- combination multi-modal therapy is important
- primary analgesics: acetaminophen, NSAIDs (often used for soft tissue injuries, strains, sprains, headaches, and arthritis), opiates
- adjuvants: antidepressants (TCAs, SSRIs), anticonvulsants (gabapentin, carbamazepine, pregabalin), baclofen, sympatholytics (phenoxymenzamine), α2-adrenergic agonists (clonidine)

**WHO Pain Ladder**
- Mild Pain: Non-opioid (acetaminophen and/or NSAID) ± adjuvant
- Moderate Pain: Opioid for mild to moderate pain (codeine/oxycodone) + non-opioid ± adjuvant
- Severe Pain: Opioid for moderate to severe pain (morphine/hydromorphone) + non-opioid ± adjuvant

**Axonal regeneration**
- directed by intact nerve sheaths; if the nerve sheath is damaged, axons grow without direction, become tangled and form a neuroma, which can result in ectopic electrical impulses and neuropathic pain
**Surgical Pain Control**
- peripheral ablation: nerve blocks, facet joint denervation
- direct delivery: implantable morphine pump
- central ablation: stereotactic thalamotomy, spinal tractotomy, or dorsal root entry lesion
- DBS or dorsal column stimulation

---

**Neuropathic Pain**

**Definition**
- pain resulting from a disturbance of the central or peripheral nervous system

**Symptoms and Signs**
- hyperalgesia/allodynia
- subjectively described as burning, heat/cold, pricking, electric shock, perception of swelling, numbness (i.e. stocking/sock distribution)
- can be spontaneous or stimulus evoked
- distribution may not fall along classical neuro-anatomical lines
- associated issues: sleep difficulty, anxiety/stress/mood alteration

**Causes of Neuropathic Pain**
- sympathetic
  - complex regional pain syndrome
- central: abnormal CNS activity
  - phantom limb, post spinal cord injury, post stroke, MS
- non-sympathetic: damage to peripheral nerves
- systemic disease: DM, thyroid disease, renal disease, rheumatoid arthritis
- nutritional/toxicity: alcoholism, pernicious anemia, chemotherapy
- infectious: post-herpetic, HIV
- trauma/compression: nerve entrapment, trigeminal neuralgia, post surgical, nerve injury, cervical/lumbar radiculopathy, plexopathy

**Treatment**
- identify/treat underlying cause
- pharmacotherapy
  - anticonvulsant: pregabalin, gabapentin, sodium valproate
  - antidepressant: amitriptyline, venlafaxine, duloxetine
  - opioids: dextromethorphan, morphine sulphate, tramadol, oxycodone
  - other: capsaicin and isosorbide dinitrate spray
- common non-pharmacologic therapies
  - percutaneous electrical stimulation (moderate evidence)
  - neuropsychiatry: CBT, psychotherapy
  - rehabilitation: physiotherapy
- surgical therapies: dorsal column neurostimulator, DBS (thalamus)

---

**Tic Douloureux (Trigeminal Neuralgia)**

**Clinical Features**
- recurrent episodes of sudden onset, excruciating unilateral paroxysmal shooting “electric” pain in trigeminal root territory (V3>V2>V1)
- may have normal sensory exam
- pain lasts seconds/minutes over days/weeks; may remit for weeks/months
- triggers: touching face, eating, talking, cold wind, shaving, applying make-up

**Etiology**
- classic TN: idiopathic
- secondary TN: compression by tortuous blood vessel (superior cerebellar artery), cerebellopontine angle tumor (5%), MS (5%)

**Epidemiology**
- F>M; usually middle-aged and elderly

**Diagnosis**
- clinical diagnosis
- investigate for secondary causes, which are more likely if bilateral TN or associated sensory loss
  - MRI to rule out structural lesion, MS, or vascular lesion
Treatmen
- first line: carbamazepine or oxcarbazepine
- second line: baclofen or lamotrigine
- narcotics not generally recommended
- if medical treatment fails: Gasserian ganglion percutaneous technique, gamma knife, invasive percutaneous denervation (radiofrequency/glycerol), percutaneous balloon microcompression, microvascular decompression

**Postherpetic Neuralgia**

**Clinical Features**
- pain persisting in the region of a cutaneous outbreak of herpes zoster
- constant deep ache or burning, intermittent spontaneous lancinating/jabbing pain, allodynia
- distribution: thoracic, trigeminal, cervical > lumbar > sacral
- associated impaired sleep, decreased appetite, decreased libido

**Etiology and Pathogenesis**
- destruction of the sensory ganglion neurons (e.g. dorsal root, trigeminal, or geniculate ganglia) secondary to reactivation of herpes zoster infection

**Epidemiology**
- incidence in those with zoster increases with age (2% in <60 yr, 19% in >70 yr)
- risk factors: older age, greater acute pain, greater rash severity

**Prevention**
- varicella zoster vaccine in childhood reduces incidence of varicella zoster
- herpes zoster vaccine (Zostavax®) reduces incidences of shingles, PHN, and other herpetic sequel (currently recommended by the Centers for Disease Control and Prevention [CDC] for those >60 yr old)

**Treatment**
- medical: TCA (i.e. amitryptiline), anti-convulsants (i.e. pregabalin, gabapentin), analgesia (i.e. opiates, lidocaine patch), intrathecal methylprednisolone, topical capsaicin
  - early treatment of acute herpes zoster with antivirals (acyclovir; longer-acting famciclovir and valacyclovir more effective)
  - treatment of herpes zoster with corticosteroids DOES NOT decrease PHN
- surgical: spinal tractotomy, dorsal root entry zone lesion, DBS of thalamus

**Painful Diabetic Neuropathy**

**Approach**
- determine if pain is neuropathic or vascular
- more likely neuropathic if
  - feet > calves
  - sharp/tingling pain
  - pain present at rest and improves with walking

**Treatment**
- Level A: pregabalin
- Level B: venlafaxine, duloxetine, amitryptyline, gabapentin, valproate, rarely opioids, capsaicin

**Complex Regional Pain Syndromes**

**Clinical Features**
- presence of an initiating noxious event (MI, stroke)
- continuing pain, allodynia, or hyperalgesia with pain disproportionate to inciting event
- evidence during the course of symptoms of edema, changes in skin blood flow or abnormal vasomotor activity
- absence of conditions that would otherwise account for degree of pain and dysfunction
- other features can include edema, osteoporosis, hyperhydrosis, hair loss, fascial thickening

**Classification**
- CRPS type I (reflex sympathetic dystrophy): minor injuries of limb or lesions in remote body areas precede onset of symptoms
- CRPS type II (causalgia): injury of peripheral nerves precedes the onset of symptoms
Investigations
• trial of differential neural blockade may be helpful in diagnosis
• autonomic testing (evidence of sympathetic dysfunction)
• bone scan, plain radiography, MRI

Prevention
• early mobilization after injury/infarction

Treatment
• goal of treatment: to facilitate function
• conservative treatment: education, support groups, PT/OT, smoking cessation
• medical: topical capsaicin, TCA, NSAID, tender point injections with corticosteroid/lidocaine, gabapentin/pregabalin/lamotrigine, calcitonin or bisphosphonates, oral corticosteroids
• surgical: paravertebral sympathetic ganglion blockade
• refer to pain management clinic

Headache

Clinical Approach
• history
  - pain characteristics: onset, frequency, duration, intensity, location, radiation, other specific features (e.g. worse in AM, worse with bending/cough/Valsalva)
  - associated symptoms: visual changes, change in mental status, N/V, fever, meningismus, photophobia, phonophobia, TMJ popping/clicking, jaw claudication, neurological symptoms
  - precipitating/alleviating factors (triggering factors, analgesics), medications (especially nitrates, CCBs, NSAIDs, anticoagulants), PMH, FHx
  - red flags (possible indications for CT scan/further investigation): new-onset headache (especially if age <5 or >50), quality worse/different than previous headaches, sudden and severe (‘thunderclap’), immunocompromised, fever, focal neurological deficits, trauma
• physical exam
  - vitals (including BP and temp), Kernig’s/Brudzinski’s, MSK examination of head and neck
  - HEENT: fundi (papilledema, retinal hemorrhages), red eye, temporal artery tenderness, sinus palpation, TMJ
  - full neurological exam (including LOC, orientation, pupils (symmetry), and focal neurological deficits)
  - red flags: papilledema, altered LOC, fever, meningismus, focal neurological deficits, signs of head trauma

Classification
• primary
  - tension, migraine, cluster, other autonomic cephalgias
• secondary
  - cervical OA, TMJ syndrome, SAH, ICH, stroke, venous sinus thrombosis, meningitis/encephalitis, trauma, increased ICP (space-occupying lesion, malignant HTN or pseudotumor cerebri), temporal arteritis, sinusitis, acute-angle closure glaucoma, pre-eclampsia, post LP, drugs/toxins (e.g. nitroglycerin use and analgesia withdrawal); all can be associated with serious morbidity or mortality

The Rational Clinical Examination: Does this Patient with Headache have a Migraine or Need Neuroimaging?

JAMA 2006;296:1274-1283

Does this patient with headache have a migraine?

The most useful panel of questions for diagnosing migraine is summarized by the POUNDing mnemonic:

P – Pulsatile quality
O – duration of 4-12 h
U – Unilateral location
N – Nausea or vomiting
D – Disabling intensity

The LR for definite or possible migraine diagnosis varies with the number of features present: with ≥4, 3, and ≥2 features, the LRs are 24 (1.5-388), 3.5 (1.3-9.2), and 0.41 (0.32-0.52), respectively.

Acute and Preventive Pharmacologic Treatment of Cluster Headache

Neurology 2010;75:463-473

Study: Meta-analysis of prospective, double-blind, RCTs of pharmacologic agents for prevention or treatment of CH.

Results: 27 trials were included. Sumatriptan 6 mg SC, zolmitriptan nasal spray 5-10 mg, and 100% oxygen 6-12 L/min received Level A recommendation for acute treatment. For prevention, Level B recommendations were given for intranasal ximamide 100 µg daily and subcutaneous steroidal injections.

Conclusion: Sumatriptan, zolmitriptan, and mid flow oxygen are effective acute treatments for CH.

Anticonvulsants in Migraine Prophylaxis

Cochrane DB Syst Rev 2009;2:CD002206

Study: Meta-analysis of prospective, controlled trials of anticonvulsant drugs in migraine headache prophylaxis.

Results: Twenty-three studies (n=2,927) were included. Anticonvulsants reduce migraine frequency by 1.3 attacks per 28 d compared to placebo and double the number of patients for whom migraine frequency is reduced by 50% (RR=2.25, I2=3.9). Valproate and topiramate are better than placebo, while clonazepam, acetazolamide, lamotrigine, and vigabatrin are not.

Clinically important adverse events were associated with valproate and topiramate with NNH 7.0-18.8, and 2.4-31.2, respectively.

Conclusion: Anticonvulsants are effective in reducing migraine frequency and reasonably well-tolerated. Valproate and topiramate are the two most studied but further studies of head-to-head comparisons between agents is needed.
Migraine Headaches

Definition (Common Migraine)
- ≥5 attacks fulfilling each of the following criteria
  - 4-72 h duration
  - 2 of the following: unilateral, pulsating, moderate-severe (interferes with daily activity), aggravated by routine physical activity
  - 1 of the following: N/V, photophobia/phonophobia/osmophobia

Epidemiology
- 18% females, 6% males; frequency decreases with age (especially at menopause)

Etiology and Pathophysiology
- theories of migraine etiology
  - depolarizing wave of “cortical spreading depression” across the cerebral cortex that may cause an aura (e.g. visual symptoms due to wave through occipital cortex) and also activate trigeminal nerve afferent fibers
  - possible association with vasoconstriction/dilation
- significant genetic contribution
- triggers: stress, sleep excess/deprivation, drugs (estrogen, nitroglycerin), hormonal changes, caffeine withdrawal, chocolate, tyramines (e.g. red wine), nitrates (e.g. processed meats)

Signs and Symptoms
- stages of uncomplicated migraine
  i. prodrome (hours to days before headache onset)
  ii. aura
  iii. headache (see Table 24 for description of typical headache)
  iv. postdrome
- aura
  - fully reversible symptom of focal cerebral dysfunction lasting <60 min
  - examples: visual disturbance (fortification spectra – zigzags; scintillating scotomata – spots), unilateral paresthesia and numbness or weakness, aphasia
- prodrome/postdrome: appetite change, autonomic symptoms, altered mood, psychomotor agitation/retardation
- classification of migraines
  - common migraine: no aura
  - classic migraine: with aura (headache follows reversible aura within 60 min)
  - complicated migraine: with severe/persistent sensorimotor deficits
    - examples
      - basilar-type migraine (occipital headache with diplopia, vertigo, ataxia, and altered level of consciousness)
      - hemiplegic/hemisensory migraine
      - ophthalmalpogeic migraine
    - acephalgic migraine (i.e. migraine equivalent): aura without headache

Management
- avoid triggers
- mild to moderate migraine
  - 1st line: NSAIDs (ibuprofen, naproxen)
  - moderate to severe migraine
    - triptans (most effective), ergots (dihydroergotamine, DHE)
    - migraine prophylaxis: anticonvulsants (divalproex, topiramate, gabapentin), TCA (amitryptiline, nortriptyline), propranolol, calcium channel blocker (verapamil)

Sleep Disorders

Overview of Sleep

Definition
- newborn: 18 h sleep (50% REM), adolescents: 10 h, adults: 7-9 h but most get insufficient amounts
- many elderly have reduced sleep as a consequence of underlying sleep disorders

Sleep Architecture
- polysomnogram (PSG) measures: EEG, eye movements (electro-oculogram – EOG), EMG, respiratory effort, oxygenation, ECG
Table 27. Sleep Stage Characteristics

</table>

Elements of Sleep History
- Initiation of sleep
  - Events prior to bed
  - Lights
  - Latency (estimated)
  - Restless legs
  - Hallucinations
- Maintaining sleep
  - Number of wakeups/night
  - Sleep walking/walking
  - Snoring/gasping
  - Dreams/nightmares
- Consequences of sleep
  - Restorative
  - Morning headache
  - Falling asleep in inappropriate setting

Disturbances of Alertness and Sleep

Coma
- see Neurosurgery, NS34

Insomnia
- definition/criteria
  - difficulty initiating or maintaining sleep, or waking up earlier than desired (leading to sleep that is chronically non-restorative/poor quality) despite adequate opportunity and circumstances for sleep
- types
  - sleep state misperception, psychophysologic insomnia (learned sleep-preventing associations – i.e. clock watching), fatal familial insomnia (rare prion protein mutation causing autonomic dysfunction), idiopathic (lifelong difficulty)
- secondary causes
  - psychiatric disorders (80% of psychiatric patients): anxiety and depression (see Psychiatry, PS10, PS7)
  - neurologic disorders: neurodegenerative disease, epilepsy, neuromuscular disorders, many others
  - sleep disorders: restless legs syndrome (sleep initiation difficulties), sleep apnea (sleep maintenance difficulties)
  - medical conditions: pregnancy, cardiorespiratory (COPD/HF), GERD, pain (arthritis, fibromyalgia, cancer)
  - drugs/toxins: caffeine, alcohol, stimulants, antidepressants, glucocorticoids, sedative withdrawal
- treatment
  - sleep log, sleep hygiene, stimulus control, sleep restriction, relaxation response, CBT

Sleep Apnea
- definition
  - disorder of breathing in sleep associated with sleep disruption and consequent excessive somnolence (or drowsiness)
- epidemiology
  - >2-4% of the population
  - increasing obesity
  - significant morbidity: HTN, stroke, heart failure, sleepiness, mortality (accidents)
- types
  - obstructive sleep apnea: see Respiratory, R31
  - central sleep apnea: no effort to breath over 10 s
  - mixed apnea: starts as central, but eventually becomes obstructive
- etiology of central apnea: heart failure, opiates, brainstem pathology, myotonic dystrophy
- diagnosis: apnea hypopnea index (AHI) or respiratory disturbance index (RDI) should be <5 in the normal state
- treatment: conservative measures, dental devices, CPAP (common), surgery (rare), ensure driving safety
Restless Leg Syndrome and Periodic Limb Movement in Sleep

- **definition**
  - urge to move with accompanied uncomfortable sensations that begin or worsen with rest, are partially or totally relieved with movement, and are worse in evening/night
  - RLS refers to sensation
  - PLMS refers to the manifestation

- **epidemiology:** 10% North Americans, 90% of RLS have PLMS, 50% of patients with PLMS have RLS

- **etiology:** central (spasticity), peripheral nervous system (radiculopathy, neuropathy), pregnancy, iron deficiency, alcohol use

- **treatment**
  - underlying contributors (iron and B12 supplementation), dopaminergic agonists (first line), clonazepam (causes tachyphylaxis), opioids (only exceptional circumstances)
  - NOT recommended: Sinemet®, causes augmentation

Narcolepsy

- **definition/clinical features:** excessive daytime sleepiness (all narcolepsy), cataplexy = loss of muscle tone with emotional stimuli (pathognomonic), sleep paralysis (unable to move upon wakening), hypnogogic hallucinations (vivid dreams or hallucinations at sleep onset)

- **epidemiology:** prevalence 1:2,000, onset in adolescence/early adulthood; life-long disorder

- **etiology:** presumed autoimmune attack on orexin/hypocretin system, post head injury, MS, hypothalamic tumors; rarely familial

- **diagnosis:** based on clinical history + multiple sleep latency test findings of short sleep latency <8 min and REM within 15 min of sleep onset on 2/4 naps

- **treatment**
  - sleep hygiene and scheduled brief naps, restricted driving
  - alerting agents modafinil (non-amphetamine stimulant), stimulant (i.e. methylphenidate)
  - anti-cataplectic: TCAs, SSRIs, sodium oxybate

Parasomnias

- **definition/clinical features:** unusual behaviors in sleep with clinical features appropriate to stage of sleep

- **etiology:** in elderly, REM sleep behavior disorder may be associated with PD; in children, slow wave sleep arousals (sleep walking) may be associated with sleep disordered breathing

- **diagnosis:** clinical history in children, polysomnography in adults to exclude nocturnal seizures

- **treatment:** behavioral management (safety, adequate sleep); clonazepam for REM sleep behavior, tonsillectomy if appropriate in children

Circadian Rhythm

- **definition/clinical features:** abnormalities based on time of day rather than sleep (i.e. jet lag, shift work)

- **diagnosis:** clinical history

---

CNS Infections

- see Infectious Diseases, ID19

Spinal Cord Syndromes

- see Neurosurgery, NS27

Stroke

---

Terminology

- **stroke:** sudden onset of neurological deficits of a vascular basis with infarction of CNS tissue
  - infarction is permanent tissue injury (confirmed by neuroimaging)
- **TIA:** sudden onset of neurological deficits of a vascular basis without infarction (i.e. resolution)
Pathophysiology

- two major types: ischemic (~80%) and hemorrhagic (~20%)

1. Ischemic
   - arterial thrombosis: thrombus formation in artery (local/in situ)
     - large vessel: stenosis or occlusion of the internal carotid artery, vertebral, or intracranial arteries
       - mechanisms
         - insufficient blood flow beyond lesion (hemodynamic stroke)
         - underlying processes: atherosclerosis (most common cause), dissection, and vasculitis
     - small vessel/lacunar
       - mechanism: chronic HTN and DM cause vessel wall thickening and decreased luminal diameter
       - affects mainly small penetrating arteries (primarily basal ganglia, internal capsule, and thalamus)
   - cardioembolic: blockage of cerebral arterial blood flow due to particles originating from a cardiac source
     - atrial fibrillation (most common), rheumatic valve disease, prosthetic heart valves, recent MI, fibrous and infectious endocarditis
   - systemic hypoperfusion (global cerebral ischemia)
     - inadequate blood flow to brain, usually secondary to cardiac pump failure (e.g. cardiac arrest, arrhythmia, or MI)
     - primarily affects watershed areas (between the major cerebral arterial territories)

2. Hemorrhagic
   - intracerebral hemorrhage
     - mechanisms
       - hypertensive (most common): rupture of small microaneurysms (Charcot-Bouchard aneurysms) causing intraparenchymal hemorrhage
       - most common sites: putamen, thalamus, cerebellum, and pons
       - other: trauma, amyloid angiopathy (associated with lobar hemorrhage), vascular malformations, vasculitis, drug use (cocaine or amphetamines)
   - subarachnoid hemorrhage see Neurosurgery, NS18

Stroke Syndromes According to Vascular Territory

- ACA: contralateral leg paresis and sensory loss
- MCA: proximal occlusion involves
  1. contralateral weakness and sensory loss of face and arm
  2. cortical sensory loss
  3. may have contralateral homonymous hemianopia or quadrantanopia
  4. if left hemisphere: aphasia
  5. if right hemisphere: neglect
  6. eye deviation towards the side of the lesion and away from the weak side
- PCA
  1. contralateral hemianopia or quadrantanopia
  2. midbrain findings: CN III and IV palsy/pupillary changes, hemiparesis
  3. thalamic findings: sensory loss, amnesia, decreased level of consciousness
  4. if bilateral: cortical blindness or prosopagnosia
- basilar artery (locked-in syndrome)
  1. quadriplegia
  2. dysarthria
  3. impaired eye movements
- PICA (lateral medullary or Wallenburg syndrome): ipsilateral ataxia, ipsilateral Horner’s, ipsilateral facial sensory loss, contralateral limb impairment of pain and temperature sensation, nystagmus, vertigo, N/V, dysphagia, dysarthria, hiccup
- medial medullary infarct (anterior spinal artery, which can be associated with anterior cord infarct): contralateral hemiparesis (facial sparing), contralateral impaired proprioception and vibration sensation, ipsilateral tongue weakness
- lacunar infarcts (deep hemispheric white matter)
  - pure motor hemiparesis (posterior limb of internal capsule): contralateral arm, leg, and face
  - pure sensory loss (thalamic): hemisensory loss
  - ataxic hemiparesis: ipsilateral ataxia and leg paresis
  - dysarthria-clumsy hand syndrome: dysarthria, facial weakness, dysphagia, mild hand weakness and clumsiness

HTN Encephalopathy
Acute severe HTN (typically dBP >130 or sBP >200) can cause hypertensive encephalopathy – abnormal fundoscopic exam (papilledema, hemorrhages, exudates, cotton-wool spots), focal neurologic symptoms, N/V, visual disturbances and change in LOC

Consider transfer of acute stroke patient to a designated stroke center for neuroprotective or thrombolytic therapy if the patient is seen in first few hours

Early seizure activity occurs in 5-25% of patients after ICH

Cerebral venous sinus thrombosis should be considered in the differential diagnosis of stroke and headache. It is an uncommon cause of either, but is associated with high morbidity and mortality. Patients often present with headache alone, but can also have seizures, focal neurological deficits, or cranial nerve palsies. This is diagnosed with MRV or CTV. Treatment is typically anticoagulation with heparin initially, then transition to warfarin

20-40% of patients with ischemic stroke may develop hemorrhagic transformation within 1 wk after the initial infarction
Assessment and Treatment of Ischemic Stroke

General Assessment
- ABCs, full vital sign monitoring, check glucose, urgent CODE STROKE if <4.5 h from symptom onset (for possible thrombolysis)
- history
  - onset: time when last known to be awake and symptom free
  - mimics to rule out: seizure/post-ictal, hypoglycemia, migraine, conversion disorder
- investigations
  - non-contrast CT head (STAT): to rule out hemorrhage and assess extent of infarct
  - ECG: to rule out atrial fibrillation (cardioembolic cause)
  - CBC, electrolytes, creatinine, PTT/INR, blood glucose
- imaging (i.e. CT) signs of stroke
  - loss of cortical white-gray differentiation
  - sulcal effacement (i.e. mass effect decreases visualization of sulci)
  - hypodensity of parenchyma
  - insular ribbon sign
  - hyperdense MCA sign

ACUTE STROKE MANAGEMENT

1. Thrombolysis
- rtPA (recombinant tissue plasminogen activator)
- given within 4.5 h of acute ischemic stroke onset provided there are clinical indications and no contraindications to use
- indications: based on NIH Stroke Scale
- contraindications: see sidebar

2. Anti-Platelet Therapy
- give at presentation of TIA or stroke if rtPA not received
- antiplatelet agents
  - ASA: recommended dose 81 mg chewed
  - if patient intolerant to ASA, use other antiplatelet agent (i.e. clopidogrel)

Aspect Score: 10-point quantitative score to assess ischemic changes on CT scan
- 10/10 is normal and <4/10 signifies high risk of bleed with rtPA
- Subtract 1 point for each of following structures if abnormal within the ischemic hemisphere: caudate, lentiform, insula, internal capsule, MCA 1, 2, 3, 4, 5, 6 regions

Infarcted area of brain tissue can often appear normal on CT during the first several hours after the onset of stroke

The National Institute of Health Stroke Scale (NIHSS) is a standardized clinical examination that determines the severity of an acute stroke; it can also be used to monitor response to treatment over time
The scale uses 11 items that evaluate:
- Level of consciousness
- Visual system
- Motor system
- Sensory system
- Language abilities
Scoring (x/42):
0=no stroke
1-4=mild stroke
5-15=moderate stroke
15-20=moderate to severe stroke
21-42=severe stroke
rtPA should be considered if score 6 or greater

Blood work should only delay treatment if: patient is on anticoagulants, low platelet count suspected, abnormal electrolytes suspected, or any bleeding abnormality suspected

Suspect an alternate diagnosis if: fever, decreased LOC, fluctuating symptoms, gradual onset, no focal neurological symptoms, and/or positive symptoms

Infarcted area of brain tissue can often appear normal on CT during the first several hours after the onset of stroke

Absolute Contraindications to rtPA
- Hx: improving sx, minor sx, seizure at stroke onset, recent major surgery (within 14 d) or trauma, recent GI or urinary hemorrhage (within 21 d), recent LP or arterial puncture at noncompressible site, PMHx ICH, sx of SAH/pericarditis/MI, pregnancy
- P/E: sBP ≥185, dBP ≥110, aggressive treatment to decrease BP, uncontrolled serum glucose, thrombocytopenia
- Ix: hemorrhage or mass on CT, high INR or aPTT
3. Acute Anti-Coagulant Therapy
- for patients with TIA or stroke and atrial fibrillation if rtPA not received
  - recommend IV heparin (or ensuring INR between 2-3 if already anticoagulated on warfarin)

Other Acute Management Issues
- avoid hyperglycemia which can increase the infarct size
- lower temperature if febrile
- prevent complications
  - NPO if dysphagia (to be reassessed by SLP)
  - DVT prophylaxis if bed-bound
  - initiate rehabilitation early

Blood Pressure Control
- do NOT lower the blood pressure unless the HTN is severe
  - antihypertensive therapy is withheld for at least 5 d after thromboembolic stroke unless sBP >220 mmHg or dBP >120 mmHg, or in the setting of acute MI, renal failure, aortic dissection
- acutely elevated BP is necessary to maintain brain perfusion to the ischemic penumbra
- most patients with an acute cerebral infarct are initially hypertensive and their BP will fall spontaneously within 1-2 d
- IV labetalol first-line if needed

Etiological Diagnosis
- further investigations
  - additional neuroimaging (MRI)
  - vascular imaging: CTA/MRA/carotid dopplers
  - cardiac tests: ECHO, holter monitoring
  - correct etiological diagnosis is critical for appropriate secondary prevention strategies

Primary and Secondary Prevention of Ischemic Stroke

Anti-Platelet Therapy
- primary prevention
  - current evidence has not firmly established a protective role for antiplatelet agents for low-risk patients without a prior stroke/TIA
- secondary prevention
  - ASA is the initial antiplatelet of choice for stroke prevention
  - other agents (generally reserved for those who suffer cerebrovascular symptoms while on ASA or if unable to tolerate ASA)
  - Aggrenox® (ESPRIT trial)
  - clopidogrel (CAPRIE trial)

Carotid Stenosis
- primary prevention (asymptomatic)
  - carotid endarterectomy is controversial: if stenosis >60%, risk of stroke is 2% per yr; carotid endarterectomy reduces the risk of stroke by 1% per yr (but 5% risk of complications)
- secondary prevention (previous stroke/TIA in carotid territory)
  - carotid endarterectomy clearly benefits those with symptomatic severe stenosis (70-99%), and is less beneficial for those with symptomatic moderate stenosis (50-69%) (NASCET trial), see Vascular Surgery, VS10
- according to the CREST trial, endarterectomy and carotid stenting have similar benefits in a composite endpoint of reduction of stroke, MI, and death; however, in the periprocedural period, stenting results in a higher rate of stroke, while endarterectomy results in a higher rate of MI

Atrial Fibrillation
- primary and secondary prevention with anticoagulation
  - risk stratification using CHADS2 score
    - 0 (very low risk): antiplatelet
    - 1 (low risk): antiplatelet or antiplatelet – patient specific decision
    - >2 (mod-high risk): anticoagulant
  - anticoagulation therapy
    - warfarin (titrate to INR 2-3)
    - dabigatran (110 or 150 mg bid) may be an option to warfarin, but should be used cautiously due to lack of a reversal agent should bleeding occur

Conclusions:
Patients receiving atorvastatin had a lower primary outcome:
First non-fatal or fatal stroke over 5 yr.

Results:
Intervention: 80 mg atorvastatin PO OD or placebo.
Population: 4,731 patients with stroke or TIA within 1-6 mo before study entry, LDL 100-190 mg/dL, no coronary heart disease.
Outcome: First non-fatal or fatal stroke over 5 yr.
Results: Patients receiving atorvastatin had a lower rate of stroke (4.8% vs. 6.5%, hazard ratio 0.72, p<0.001).
Conclusion: Dabigatran at 110 mg PO bid was associated with similar rates of stroke and systemic embolism and lower rates of major hemorrhage compared to warfarin in patients with atrial fibrillation. The 150 mg PO bid dose of dabigatran was more effective at stroke prevention and had a similar bleeding risk to warfarin.

CHADS2 Stroke risk stratification for patients with atrial fibrillation
- CHF (1 point)
- HTN sBP >160 mmHg/treated HTN (1 point)
- Age >75 yr (1 point)
- DM (1 point)
- Prior Stroke or TIA (2 points)
**Hypertension**
- **primary prevention**
  - targets: BP <140/90 (or <130/80 for diabetics or renal disease)
  - ramipril 10 mg PO OD is effective in patients at high risk for cardiovascular disease (HOPE trial)
    - ACEI reduce the risk of stroke beyond their antihypertensive effect
- **secondary prevention**
  - ACEI and thiazide diuretics are recommended in patients with previous stroke/TIA (PROGRESS trial)

**Hypercholesterolemia**
- **primary prevention**
  - statins reduce the risk of stroke in patients with CAD or at high risk for cardiovascular events, even with normal cholesterol (CARE trial)
- **secondary prevention**
  - statins reduce risk of subsequent stroke – best evidence is for high dose atorvastatin (SPARCL trial) but lower doses may be more appropriate if patient cannot tolerate high dose

**Diabetes**
- ideal management: HbA1c <7%, fasting blood glucose between 4 and 7

**Smoking**
- **primary prevention**
  - smoking increases risk of stroke in a dose-dependent manner
- **secondary prevention**
  - after smoking cessation, the risk of stroke decreases to baseline within 2-5 yr

**Physical Activity**
- regular physical activity is an important lifestyle measure in stroke prevention and its beneficial effect has a dose-related response in terms of intensity and duration of activity

**Stroke Rehabilitation**
- individualized based on severity and nature of impairment; may require inpatient program and continuation through home care or outpatient services
- multidisciplinary approach includes dysphagia assessment and dietary modifications, communication rehabilitation, cognitive and psychological assessments including screen for depression, therapeutic exercise programs, assessment of ambulation and evaluation of need for assistive devices, splints or braces, vocational rehabilitation

**Cerebral Hemorrhage**

**Investigations**
- general investigations, see *Assessment and Treatment of Ischemic Stroke, N49*
- further investigations
  - LP (if suspect subarachnoid hemorrhage despite negative CT)
  - may require cerebral angiogram if suspect aneurysm or AVM
  - if typical location for hypertensive hemorrhage, repeat CT head in 4-6 wk after hemorrhage has resolved to rule out an underlying lesion

**Management**
- medical
  - anti-hypertensives: no conclusive BP target ranges for managing ICH exist; 2010 AHA/ASA guidelines suggest that reducing sBP to as low as 140 mmHg with IV anti-hypertensives is safe and appropriate management (target sBP 140-160)
  - ICP lowering medical management (if necessary): see *Neurosurgery, NS7*
- surgical: see *Neurosurgery, NS19*
Multiple Sclerosis

Definition
- a chronic inflammatory disease of the CNS characterized by relapsing remitting, or progressive neurologic symptoms due to inflammation, demyelination, and axonal degeneration

Clinical Patterns of MS
- relapsing remitting (RRMS) 85%, primary progressive (PPMS) 10%, progressive relapsing (PRMS) 5%, secondary progressive (SPMS)
- most RRMS goes on to become SPMS

MS Variants
- Devic’s = neuromyelitis optica (NMO): severe optic neuritis and extensive transverse myelitis extending >3 vertebral segments (NMO antibody positive)
- clinically isolated syndrome (CIS): single MS-like episode, which may progress to MS
- tumefactive MS: solitary lesion >2 cm mimicking neoplasms on MRI
- fulminant MS (Marburg): rapidly progressive and fatal MS associated with severe axonal damage, inflammation, and necrosis
- acute disseminated encephalomyelitis (ADEM): monophasic demyelinating disorder with multifocal neurologic symptoms seen mainly in children often following infection or vaccination

Etiology
- genetic
  - polygenic: the HLA-DRB1 gene has been demonstrated to be a genetically susceptible area
  - 30% concordance for monozygotic twins, 2-4% risk in offspring of affected mother or father
- environmental
  - MS is more common in regions with less sun exposure and lower stores of vitamin D (Europe, Canada, US, New Zealand, SE Australia)
  - MS has also been linked to certain viruses (EBV is associated with MS)

Epidemiology
- onset 17-35 yr; F:M = 3:1
- PPMS occurs in an older population with F:M

Diagnosis
- dissemination in space and in time as based on the revised McDonald criteria
  - dissemination in time: 2 or more attacks, new gadolinium enhancing lesion 3 mo later, or new T2 lesions >1 mo after first attack
  - dissemination in space: clinical evidence of 2 or more lesions; or three of (1 gadolinium enhancing or 9 T2 lesions), (1 infratentorial lesion), (1 juxtacortical lesion), (3 periventricular lesions)

Clinical Features
- symptoms include numbness, visual disturbance (optic neuritis), weakness, spasticity, diplopia (e.g. INO), impaired gait, vertigo, bladder dysfunction
- Lhermitte's sign: flexion of neck causes electric shock sensation down back into limbs indicating cervical cord lesion
- Uhthoff’s phenomenon: worsening of symptoms (classically optic neuritis) in heat
- SPMS: classically weakness of legs in pyramidal distribution paired with cerebellar findings of arms (i.e. intention tremor)
- symptoms not commonly found in MS: visual field defects, aphasia, apraxia, progressive hemiparesis
- relapse: acute/subacute onset of clinical dysfunction that peaks from days to weeks, followed by remission with variable symptom resolution (symptoms must last at least 24 h)
- in RRMS, average 0.4 to 0.6 relapses/yr, but higher disease activity in first yr of disease

Investigations
- MRI: demyelinating plaques appear as hyperintense lesions on T2 weighted MRI, with active lesions showing enhancement with gadolinium
  - typical locations: periventricular, corpus callosum, cerebellar peduncles, brainstem, juxta cortical region, and dorsolateral spinal cord
  - Dawson’s fingers: periventricular lesions extending into corpus callosum
  - cranial MRI is more sensitive than spinal MRI
- CSF: oligoclonal bands in 90%, increased IgG concentration
- evoked potentials (visual/auditory/somatosensory): delayed but well-preserved wave forms

Figure 25. Clinical patterns of MS

Chronic Cerebrospinal Venous Insufficiency (CCSVI)
A theory proposed in 2008 describing abnormal venous blood flow in patients with MS. While some RCTs are still underway, recent studies have largely discredited this highly controversial theory. That is, studies indicate no connection between CCSVI and MS

Most symptoms in MS are due to cord, brainstem, and optic nerve lesions

The Expanded Disability Status Scale (EDSS) is used as a measure of disability progression and is scored from 0 to 10 based on the neurologic exam and ambulation

Recombinant Interferon Beta or Glatiramer Acetate for Delaying Conversion of the First Demyelinating Event to Multiple Sclerosis
Cochrane DB Syst Rev 2008;2:CD005278
Study: Meta-analysis of RCTs of clinically isolated syndrome (CIS) patients treated with immunomodulatory drugs.
Primary Outcomes: Proportion of patients converting to clinically definite MS and adverse effects.
Results: Three trials (n=1,160) tested the efficacy of interferon (IFN-β) and no trial tested glatiramer acetate (GA). A pooled odds ratio (OR) of 0.53 (95% CI 0.40-0.71, p<0.0001) for patients on IFN vs. placebo at 1 yr. Two year follow-up odds ratio was 0.52 (95% CI 0.38-0.70, p<0.0001). There was no significant increase in adverse events for those on IFN-β.
Conclusions: IFN-β treatment can delay progression to clinically definite MS in patients with CIS over 2 yr.
Treatment
- **acute treatment**: methylprednisolone 1,000 mg IV daily x 3-7 d (no taper required); if poor response to corticosteroids may consider plasma exchange
- **disease modifying therapy**
  - goals: decrease relapse rate, decrease progression of disability, slow accumulation of MRI lesions
  - first line: interferon-β (injection: Betaseron®, Avonex®, Rebif®), glatiramer acetate (injection: Copaxone®)
  - second line: natalizumab (Tysabri®) (monthly IV infusion)
  - new oral agents: fingolimod (available) and cladribine (not yet available)
  - indications for fingolimod: newly diagnosed patients with active RRMS who prefer oral treatment despite increased risks or those intolerant of first line therapies
  - CIS: early treatment with interferons may delay potential second attack
  - RRMS: DMT reduces rate of relapse by about 30%
  - PPMS/SPMS: no proven efficacy of DMTs
- **symptomatic treatment**
  - spasticity: baclofen, tizanidine, dantrolene, benzodiazepine, botulinum toxin
  - bladder dysfunction: oxybutynin
  - pain: TCA, carbamazepine, gabapentin
  - fatigue: amantidine, modafinil, methylphenidate
  - depression: antidepressant, lithium
  - constipation: high fiber intake, stool softener, laxatives
  - sexual dysfunction: sildenafil, tadenafil, vardenafil
- **education and counseling**: MS Society, support groups, psychosocial issues

Prognosis
- good prognostic indicators: female, young, RRMS, presenting with optic neuritis, low burden of disease on initial MRI, low rate of relapse early in disease
- PPMS: poor prognosis, higher rates of disability, poor response to therapy

Oral Fingolimod or Intramuscular Interferon for Relapsing Multiple Sclerosis
*NEJM* 2010;362;402-415

**Method:** Multicenter double-blind RCT.
**Population:** 1,292 patients with relapsing-remitting MS and at least one relapse.
**Intervention:** Oral fingolimod at 0.5-1.25 mg or 30 µg IM interferon-β.
**Outcomes:** Annualized relapse rate over 1 yr; lesions on T2-weighted MRI.
**Results:** Annualized relapse rate was lower in both groups receiving fingolimod compared to interferon: 0.20 (95% CI 0.16-0.26) with 1.25 mg fingolimod, 0.16 (95% CI 0.12-0.21) with 0.5 mg fingolimod, 0.33 with interferon (95% CI 0.26-0.42; p<0.001). MRI findings also showed greater reduction of lesions in fingolimod-treated patients. Progression of disability was unchanged. Side effects included severe infections like HSV encephalitis, disseminated VZV, other HSV infections, and skin cancer.
**Conclusions:** Oral fingolimod is superior to interferon-β injections in reducing relapses and MRI lesion load in patients with MS.

</table>
ICP/Volume Relationship

- Adult skull is rigid with a constant intracranial volume
- Contents (CSF, blood, brain) are incompressible
- Increase in one constituent/space-occupying lesion = 1) increase in ICP, 2) require redistribution of CSF, blood, brain
- However, ICP does not rise initially due to compensatory mechanisms
  - Immediate: displacement of CSF to lumbar theca, displacement of blood from venous sinuses
  - Delayed: displacement of ECF or ICF, displacement of brain tissue into compartments under less pressure (herniation)
- Once compensation is exhausted, ICP rises exponentially

Cerebral Blood Flow

- Brain receives about 15% of cardiac output (~750 mL/min)
- CBF depends on cerebral perfusion pressure (CPP) and cerebral vascular resistance (CVR)
- Normal CPP >50 mmHg in adults
- Cerebral autoregulation maintains constant CBF by compensating for changes in CPP, unless:
  - High ICP such that CPP <60 mmHg
  - MAP >150 mmHg or MAP <50 mmHg
  - Brain injury: e.g. SAH, severe trauma

ICP Measurement

- Normal ICP <15 mmHg (8-18 cmH2O) for adult, 3-7 mmHg (4-9.5 cmH2O) for child; varies with patient position
- Moderate elevation: increase in mean pressure >20 mmHg
- Severe elevation: increase in mean pressure >40 mmHg
- Waveform: comprised of respiratory and cardiac pulsations (Traube-Hering waves); the amplitude increases with ICP
  - Beta-waves: coarse, variably increased amplitude, frequency ½-2/min, often related to respiration
  - Plateau waves: elevation of ICP over 50 mmHg lasting 5-20 min, precursor of further deterioration

Acute Monitoring

- Lumbar puncture (LP)
- Intraventricular catheter/ventriculostomy/external ventricular drain (EVD) (“gold standard”, also permits therapeutic drainage of CSF to decrease ICP)

Chronic Monitoring

- Fiberoptic monitor (intraventricular, intraparenchymal, subdural), subarachnoid bolt (Richmond screw), and epidural monitor

Elevated ICP

Etiology

- Intracranial space-occupying lesion
  - Tumor
  - Pus
  - Blood (trauma → hematoma [most common], subarachnoid hemorrhage)
  - Depressed skull fracture
  - Foreign body
- Increased intracranial blood volume
  - Vasodilatation (increased pCO2/decreased pO2/decreased extracellular pH, e.g. hypoventilation)
  - Venous outflow obstruction (venous sinus thrombosis, superior vena cava syndrome, space-occupying lesion)
  - Cranial dependency
- Cerebral edema
  - Vasogenic (vessel damage, e.g. hypertensive encephalopathy, tumor)
  - Cytotoxic (tissue/cell death, e.g. hypoxia, brain injury)
  - Osmotic (acute hyponatremia, hepatic encephalopathy)
- hydrocephalus
  - obstructive: acquired aqueductal stenosis
  - non-obstructive: decreased CSF absorption with SAH
- pseudotumor cerebri (idiopathic intracranial HTN)
- impaired autoregulation (hypotension, HTN, brain injury)
- status epilepticus (chronic seizure resulting in brain edema)

Clinical Features
1. Acute Elevated ICP
   - H/A: worse in the morning, aggravated by stooping, and bending
   - N/V
   - decreased LOC if ICP = dBP, or midbrain compressed
   - drop in GCS = best index to monitor progress and predict outcome of acute intracranial process (see Neurotrauma, NS29)
   - papilledema ± retinal hemorrhages (may take 24-48 h to develop)
   - abnormal extra-ocular movements (EOM):
     - CN VI palsy: often falsely localizing (causative mass may be remote from nerve)
     - upward gaze palsy (especially in children with obstructive hydrocephalus)
   - herniation syndromes
   - focal signs/symptoms due to lesion

2. Chronic Elevated ICP
   - H/A
     - postural: worsened by coughing, straining, and bending over
     - morning/evening H/A → vasodilatation due to increased CO2 with recumbency
   - visual changes
     - due to papilledema
     - enlarged blind spot, if advanced → episodic constrictions of visual fields ("gray-outs")
     - optic atrophy/blindness
     - differentiate from papillitis (usually unilateral with decreased visual acuity)
   - decreased level of consciousness

Investigations
- patients with suspected elevated ICP require an urgent CT/MRI
- ICP monitoring where appropriate

### Herniation Syndromes

</tbody>
</table>

Blood Brain Barrier
- Glucose and amino acids cross slowly
- Non-polar/lipids cross fast

Blood Brain Barrier
- Infarction/neoplasm → destroy tight junctions → vasogenic edema

Cushing’s Triad of Acute Raised ICP
- HTN
- Bradycardia (late finding)
- Irregular respiratory pattern

Papilledema
- Optic disc swelling with blurred margins (most commonly bilateral)
- Larger blind spot

Figure 6. Herniation types

© Heidi Maj
Treatment of Elevated ICP

- CT or MRI to identify etiology, assess for midline shift/herniation
- treat primary cause (i.e. remove mass lesions, ensure adequate ventilation)
- if elevated ICP persists following treatment of primary cause, consider therapy when ICP >20 mmHg
- goals: keep ICP <20 mmHg, CPP >65 mmHg, MAP >90 mmHg

Conservative Measures
- elevate head of bed at 30°, maintain neck in neutral position → increases intracranial venous outflow with minimal effect on arterial pressure
- prevent hypotension with fluid and vasopressors, dopamine, norepinephrine prn
- ventilate to normocarbia (pCO₂ 35-40 mmHg) → prevents vasodilatation
- oxygen to maintain pO₂ >60 mmHg → prevents hypoxic brain injury
- osmolar diuresis (mannitol 20% IV solution 1-1.5 g/kg, then 0.25 g/kg q6h to serum osmolarity of 315-320)
  - can give rapidly, acts in 15-30 min, must maintain sBP >90 mmHg
- corticosteroids → decrease edema over subsequent days around brain tumor, abscess, blood
  - no proven value in head injury or stroke

Aggressive Measures
- sedation ("light" e.g. barbiturates/codeine → "heavy" e.g. fentanyl/MgSO₄)
- paralysis with vecuronium → reduces sympathetic tone, reduces HTN induced by muscle contraction
- hyperventilate to pCO₂ 30-35 mmHg
  - use for brief periods only – also results in decreased cerebral blood flow
- drain 3-5 mL CSF via ventricles, assess each situation independently
- insert EVD (if acute) or shunt
- barbiturate-induced coma induced with pentobarbital to reduce cerebral blood flow and metabolism (10 mg/kg over 30 min, then 1 mg/kg q1h continuous infusion)
  - decreases mortality, but no improvement in neurological outcome
- decompressive craniectomy is a last resort
- no role for the use of hypothermia in head injury

Hydrocephalus

- hydrocephalus in children, see Pediatric Neurosurgery, NS36

Definition
- accumulation of excess CSF in the brain
- CSF: produced by choroid plexus lateral ventricles
- total volume ~120 mL, including 30 cc within ventricular system, remainder in SA space
- flow: lateral ventricle → 3rd ventricle → cerebral aqueduct → 4th ventricle → subarachnoid space
- re-absorbed by arachnoid villi into dural venous sinuses

Etiology
- congenital vs. acquired
- obstruction to CSF flow
- decreased CSF absorption
- increased CSF production (rarely) – e.g. choroid plexus papilloma (0.4-1% of intracranial tumors)

Epidemiology
- estimated prevalence 1-1.5%; incidence of congenital hydrocephalus ~1-2/1,000 live births

Figure 7. The flow of CSF
## Classification

</tbody>
</table>

### Clinical Features
- acute hydrocephalus
  - signs and symptoms of acute elevated ICP (see Elevated ICP, NS5)
  - impaired upward gaze ("sunset eyes") and/or CN VI palsy
- chronic/gradual onset hydrocephalus (i.e. NPH)
  - gradual onset of classic triad developing over weeks or months
    - pressure of ventricle on lower extremity motor fibers → gait disturbance (ataxia and apraxia usually initial symptoms)
    - pressure on cortical bowel/bladder center → urinary incontinence
    - pressure on frontal lobes → dementia
  - CSF pressure can be measured within clinically "normal" range

### Investigations
- CT/MRI (periventricular lucency suggests raised CSF pressure)
- ultrasound (through anterior fontanelle in infants)
- ICP monitoring (e.g. LP) may be used to investigate NPH, test response to shunting (lumbar tap test)
- radionuclide cisternography can test CSF flow and absorption rate (unreliable)
- β-2 transferrin assay to test for the presence of CSF leak

### Treatment
- ventricular drainage
- surgical removal of obstruction (if possible) or excision of choroid plexus papilloma
- shunts
  - ventriculoperitoneal (VP): most common
  - ventriculopleural
  - ventriculo-atrial (VA): relatively increased risk of infections, shunt emboli
  - lumbo-peritoneal: for communicating hydrocephalus and pseudotumor cerebri
- third ventriculostomy (for obstructive hydrocephalus) via ventriculoscopy
- LPs for transient hydrocephalus (e.g. SAH), IVH in premature infants, etc.
### Shunt Complications

### Idiopathic Intracranial Hypertension (Pseudotumor Cerebri)

**Definition**
- raised intracranial pressure and papilledema without evidence of any mass lesion, hydrocephalus, infection, or hypertensive encephalopathy (diagnosis of exclusion)

**Etiology**
- unknown (majority), but associated with
  - lateral venous sinus thrombosis
  - habitus/diet: obesity, hyper/hypovitaminosis A
  - endocrine: reproductive age, menstrual irregularities, Addison's/Cushing's disease, thyroid irregularities
  - hematological: iron deficiency anemia, polycythemia vera
  - drugs: steroid administration or withdrawal, tetracycline, nalidixic acid, etc.
- risk factors overlap with those of venous sinus thrombosis; similar to those for gallstones (“fat, female, fertile, forties”)

**Epidemiology**
- incidence ~0.5/100,000 per year
- usually in 3rd and 4th decade (F>M)

**Clinical Features**
- symptoms and signs of raised ICP (H/A in >90%, pulsatile intracranial noise), but no LOC or diplopia
- decreased visual acuity, papilledema, visual field defect, optic atrophy (key morbidity)
- usually self-limited, recurrence is common, chronic in some patients
- risk of blindness is not reliably correlated to symptoms or clinical course

**Important Features to Note on CT and MRI (± contrast enhancement)**
- Lesions (± edema, recessis, hemorrhage)
- Midline shifts and herniations
- Effacement of ventricles and sulci (often ipsilateral), basal cisterns
- Single or multiple (multiple implies metastasis)
Investigations
- CT: normal
- CSF studies: normal
- MRI: must look for venous sinus thrombosis

Treatment
- rule out conditions that cause intracranial HTN (especially sinus thrombosis)
- discontinue offending medications, encourage weight loss, fluid/salt restriction
- pharmacotherapy: acetazolamide (decreases CSF production), thiazide diuretic, or furosemide
- if above fail: serial LPs, shunt
- optic nerve sheath decompression (if progressive impairment of visual acuity)
- 2 yr follow-up with imaging to rule out occult tumor, ophthalmology follow-up

Tumors

Classification
- primary vs. metastatic, intra-axial (parenchymal) vs. extra-axial, supratentorial vs. infratentorial, adult vs. pediatric
- benign: non-invasive, but can be devastating due to expansion of mass in fixed volume of skull (mass effect)
- malignant: implies rapid growth, invasiveness, but rarely extracranial metastasis
- types of intracranial tumors (* = most common)
  - neuroepithelial tissue
    - astrocytic tumors: astrocytoma, glioblastoma
    - oligodendrogial tumors
    - oligoastrocytic tumors
    - neuronal and mixed neuronal-glial tumors: ganglion cell tumors, cerebral neurocytomas/neuroblastomas
    - embryonal tumors: medulloblastoma, neuroectodermal
    - other: pineal, ependymal, and choroid plexus tumors
  - meningeal: meningiomas*, mesenchymal, hemangioblastomas
  - cranial and paraspinal nerves: schwannoma, neurofibroma
  - lymphomas and hematopoietic neoplasms
  - germ cell: germinomas, teratomas
  - pituitary adenomas*
  - sellar region: craniopharyngiomas, spindle cell oncocytoma
  - cysts: epidermoid/dermoid cysts, colloid cysts
  - local extension: chordomas, glomus jugulare tumors
  - metastatic tumors

Clinical Features
- supratentorial lesions
  - progressive neurological deficit (70%)
    - frontal lobe: hemiparesis, dysphasia, personality changes, cognitive changes
    - temporal lobe: auditory/olfactory hallucinations, memory deficits, contralateral superior quadrantanopsia

Primary Sources of Metastatic Brain Tumors
Lung 44%
Breast 10%
Kidney (RCC) 7%
GI 6%
Melanoma 3%

Primary CNS lymphoma reported in 6-20% of HIV infected patients

Brain Metastasis
- 1/3 of all adult brain tumors
- Well circumscribed, often at gray-white matter junction

Primary Brain Tumors
- Rarely undergo metastasis
- Adults = mostly supratentorial
- Children = mostly infratentorial
- parietal lobe: contralateral sensory or motor impairment, apraxia
- occipital lobe: contralateral visual field deficits, alexia
- H/A (50%) ± symptoms of elevated ICP (N/V, papilledema)
- seizures (25%)
- symptoms suggestive of TIA (ictal, post-ictal, occlusion of vessel by tumor cells or "steal phenomenon")
- endocrine disturbances with pituitary tumors
- rarely presents with hemorrhage

**Infratentorial lesions**
- most commonly presents with signs of elevated ICP
  - H/A
  - N/V
  - papilledema
- diplopia (direct compression CN VI vs. indirect compression from increased ICP)
- vertigo
- ataxia (due to cerebellar lesions)

**Familial syndromes associated with CNS tumors**
- von Hippel-Lindau (hemangioblastoma of brain, spinal cord, and eye)
- tuberous sclerosis (giants cell astrocytoma, cortical tubers, and supependymal nodules)
- neurofibromatosis type 1 and 2 (astrocytoma, acoustic neuroma respectively)
- Li-Fraumeni (astrocytoma)
- Turcot syndrome (glioblastoma multiforme)
- multiple endocrine neoplasia type 1 (MEN-1) (pituitary adenoma)

**Investigations**
- CT, MRI, stereotactic biopsy (tissue diagnosis), metastatic workup

**Treatment**
- conservative: serial Hx, Px, imaging for slow growing/benign lesions
- medical: corticosteroids to reduce cytotoxic cerebral edema, pharmacological (see **Pituitary Adenoma, NS13**)
- surgical: total or partial excision (decompressive, palliative), shunt if hydrocephalus
- radiotherapy: conventional fractionated radiotherapy (XRT), stereotactic radiosurgery (e.g. Gamma Knife)
- chemotherapy: e.g. alkylating agents (temozolomide)

</tbody>
</table>

**Metastatic Tumors**
- most common brain tumor seen clinically
- 15-30% of cancer patients present with cerebral metastatic tumors
- most common sources: lungs, breast
- other sources: kidney, thyroid, stomach, prostate, testis, melanoma
- hematogenous spread most common

**Location**
- 80% are hemispheric, often at gray-white matter junction or junction of temporal-parietal-occipital lobes (likely emboli spreading to terminal MCA branches)

**Investigations**
- identify primary tumor
  - metastatic workup (CXR, CT chest/abdo, abdominal U/S, bone scan, mammogram)
  - CT with contrast → round, well-circumscribed, often ring enhancing, ++ edema, often multiple
  - MRI more sensitive, especially for posterior fossa
  - consider biopsy in unusual cases, or if no primary identified
Treatment
- medical
  - phenytoin (or levetiracetam) for seizure prophylaxis if patient presents with seizure
  - dexamethasone to reduce edema given with ranitidine
  - chemotherapy (e.g. small cell lung cancer)
- radiation
  - stereotactic radiosurgery: for discrete, deep-seated/inoperable tumors
  - multiple lesions: use WBRT; consider stereotactic radiosurgery if <3 lesions
  - post-operative WBRT is commonly used
- surgical
  - single/solitary lesions: use surgery + radiation

Prognosis
- median survival without treatment once symptomatic is ~1 mo, with optimal treatment 6-9 mo but varies depending on primary tumor type

**Astrocytoma**
- most common primary intra-axial brain tumor, common in 4th-6th decades

<table>

</tr>
</tbody>
</table>

Clinical Features
- sites: cerebral hemispheres >> cerebellum, brainstem, spinal cord
- symptoms: recent onset of new/worsening H/A, N/V, seizure, ± focal deficits or symptoms of increased ICP

Investigations
- CT/MRI with contrast: variable appearance depending on grade (see Table 8)
  - hypodense on CT, hypointense on T1 MRI, hyperintense on T2 MRI
  - low grade: most do not enhance and have calcification on CT
  - high grade: most enhance with CT contrast dye/gadolinium
- tissue biopsy: WHO grade and histology correlates with prognosis, but 25% chance of sampling error due to tumor heterogeneity

Treatment
- low grade diffuse astrocytoma
  - close follow-up, radiation, chemotherapy, and surgery all valid options
  - surgery: not curative, trend towards better outcomes
  - radiotherapy alone or post-operative prolongs survival (retrospective evidence)
  - chemotherapy: usually reserved for tumor progression
- high grade astrocytomas (anaplastic astrocytoma and GBM)
  - surgery
    - gross total resection: maximal safe resection +fractionated radiation with 2 cm margin + concomitant and adjuvant temozolomide
    - except: extensive dominant lobe GBM, significant bilateral involvement, end-of-life near, extensive brainstem involvement
    - stereotactic biopsy if resection not possible, followed by fractioned radiation with 2 cm margin
  - expectant (based on functional impairment – Karnofsky score <70; patient’s/family’s wishes)
  - aim to prolong “quality” survival
  - chemotherapy: ~20% response rate, temozolomide (agent of choice); better response to temozolomide predicted by MGMT gene hypermethylation
- multiple gliomas: WBRT ± chemotherapy

**Meningioma**
- most common primary intracranial tumor, arise from arachnoid membrane
- often calcified, cause hyperostosis of adjacent bone
- classically see Psammoma bodies on histology
- common locations: parasagittal convexity or falx (70%), sphenoid wing, tuberculum sellae, foramen magnum, olfactory groove
Clinical Features

- middle aged, slight female preponderance (M:F = 2:3), high progesterone receptors (increase in size with pregnancy), symptoms of increased ICP, focal deficits, usually solitary (10% multiple, likely with loss of NF2 gene/22q12 deletion)

Investigations

- CT with contrast: homogeneous, densely enhancing, along dural border (“dural tail”), well circumscribed
- contrast enhanced MRI provides better detail
- angiography
  - most are supplied by external carotid feeders (meningeal vessels)
  - also assesses venous sinus involvement, “tumor blush” commonly seen (prolonged contrast image)
- octreotide scintigraphy: to establish if expression of somatostatin receptor

Treatment

- conservative management for non-progressive, asymptomatic lesions
- surgery is treatment of choice if symptomatic or progression on sequential imaging (curative if complete resection)
- SRS may be an option for lesions <3 cm
- endovascular embolization to facilitate surgery
- SRS or XRT for recurrent atypical/malignant meningiomas

Prognosis

- >90% 5 yr survival, recurrence rate variable (often ~10-20%)
- depends on extent of resection (Simpson's classification)

Vestibular Schwannoma (Acoustic Neuroma)

- slow-growing (average of 1-10 mm/yr), benign posterior fossa tumor
- arises from vestibular component of CN VIII in internal auditory canal, expanding into bony canal and cerebello-pontine angle (CPA)
- if bilateral, diagnostic of neurofibromatosis type II
- epidemiology: all age groups affected, peaks at 4th-6th decades

Clinical Features

- compression of structures in CPA, often CN VIII (unilateral hearing loss 98%, tinnitus, disequilibrium), followed by CN V and VII
- ataxia and raised ICP are late features

Investigations

- MRI with gadolinium or T2 FIESTA sequence (>98% sensitive/specific), CT with contrast 2nd choice
- audiogram, brainstem auditory evoked potentials, caloric tests

Treatment

- conservative: serial imaging (CT/MRI q6mo) and audiometry
- radiation: stereotactic radiosurgery or fractionated radiotherapy
- surgery if: lesion >3 cm, brainstem compression, edema, hydrocephalus
  - curable if complete resection (almost always possible)
  - operative complications: CN VII, VIII dysfunction (only significant disability if bilateral), CSF leak

Pituitary Adenoma

- primarily from anterior pituitary, 3rd-4th decades, M=F
- incidence in autopsy studies approximately 20%
- classification
  - microadenoma <1 cm; macroadenoma ≥1 cm
  - endocrine active (functional/secretory) vs. inactive (non-functional)
    - most common functional: prolactinomas, adrenocorticotropic, growth-hormone producing
  - differential: parasellar tumors (e.g. craniopharyngioma, tuberculum sellae meningioma), carotid aneurysm
Clinical Features

- mass effects
  - H/A
  - bitemporal hemianopsia (compression of optic chiasm)
  - CN III, IV, V₁, V₂, VI palsy (compression of cavernous sinus)
- endocrine effects
  - hyperprolactinemia (prolactinoma): infertility, amenorrhea, galactorrhea, decreased libido
  - ACTH production: Cushing’s disease, hyperpigmentation
  - GH production: acromegaly/gigantism
  - panhypopituitarism (hypothyroidism, hypoadrenalism, hypogonadism)
  - associated MEN-1 syndrome
  - diabetes insipidus
- pituitary apoplexy (sudden expansion of mass due to hemorrhage or necrosis)
  - abrupt onset H/A, visual disturbances, ophthalmoplegia, reduced mental status, and panhypopituitarism
  - CSF rhinorrhea and seizures (rare)
  - signs and symptoms of subarachnoid hemorrhage (rare)

Investigations

- formal visual fields, CN testing
- endocrine tests (prolactin level, TSH, 8 AM cortisol, fasting glucose, FSH/LH, IGF-1), electrolytes, urine electrolytes, and osmolarity
- imaging (MRI with and without contrast)

Treatment

- medical
  - for apoplexy: rapid corticosteroid administration ± surgical decompression
  - for prolactinoma: dopamine agonists (e.g. bromocriptine)
  - for Cushing’s: serotonin antagonist (cyproheptadine), inhibition of cortisol production (ketoconazole)
  - for acromegaly: somatostatin analogue (octreotide) ± bromocriptine
  - endocrine replacement therapy
- surgical
  - trans-sphenoidal, trans-ethmoidal, trans-cranial approaches for non-secreting adenomas causing mass effect and Cushing/acromegaly (50% cure rate)

Pus

Sources of Pus/Infection

- four routes of microbial access to CNS
  1. hematogenous spread (most common): arterial and retrograde venous
     - adults: chest is #1 source (lung abscess, bronchiectasis, empyema)
     - children: congenital cyanotic heart disease with R to L shunt
     - immunosuppression (AIDS – toxoplasmosis)
  2. direct implantation (dural disruption)
     - trauma
     - iatrogenic (e.g. following LP, post-operative)
     - congenital defect (e.g. dermal sinus)
  3. contiguous spread (adjacent infection): from air sinus, naso/oropharynx, surgical site
     - e.g. otitis media, mastoiditis, sinusitis, osteomyelitis, dental abscess
  4. spread from PNS (e.g. viruses: rabies, herpes zoster)
- common examples
  - epidural abscess: in cranial and spinal epidural space, associated with osteomyelitis
    - treatment: immediate drainage and antibiotics, surgical emergency if cord compression
  - subdural empyema: bacterial/fungal infection, due to contiguous spread from bone or air sinus, progresses rapidly
    - treatment: surgical drainage and antibiotics, 20% mortality
  - meningitis, encephalitis (see Infectious Diseases, ID19, ID20)
  - cerebral abscess

Cerebral Abscess

Definition

- pus in brain substance, surrounded by tissue reaction (capsule formation)

Etiology

- modes of spread: 10-60% of patients have no cause identified
- pathogens
  - Streptococcus (most common), often anaerobic or microaerophilic
  - Staphylococcus (penetrating injury)
  - Gram-negatives, anaerobes (Bacteroides, Fusobacterium)
  - in neonates: Proteus and Citrobacter (exclusively)
immunocompromised: fungi and protozoa (Toxoplasma, Nocardia, Candida albicans, Listeria monocytogenes, Mycobacterium, and Aspergillus)

Risk Factors
- fungal abnormalities (infection, AV fistulas; especially Osler-Weber-Rendu syndrome [i.e. hereditary hemorrhagic telangiectasia])
- congenital coronary heart disease: R-to-L shunt bypasses pulmonary filtration of micro-organisms
- bacterial endocarditis
- penetrating head trauma
- immunosuppression (e.g. AIDS)
- dental abscess

Clinical Features
- focal neurological signs and symptoms
- H/A, decreased LOC; hemiparesis and seizures in 50%
- mass effect, increased ICP and sequelae (cranial enlargement in children)
- hemiparesis and seizures in 50%
- ± signs and symptoms of systemic infection (low-grade fever, leukocytosis)

Complications
- with abscess rupture: ventriculitis, meningitis, venous sinus thrombosis
- CSF obstruction
- transtentorial herniation

Investigations
- CT scan often first test in emergency department (see Figure 13)
- MRI
  - imaging of choice
  - apparent diffusion coefficient (ADC) used to differentiate abscess (black) from tumor (white)
- WBC/ESR may be normal, blood cultures rarely helpful and LP contraindicated if large mass
- CSF: non-specific (high ICP, high WBC, high protein, normal carbohydrate), rarely helpful, usually negative culture

Treatment
- aspiration ± excision and send for Gram stain, acid fast bacillus (AFB), C&S, fungal culture
- excision preferable if location suitable
- antibiotics
  - empirically: vancomycin + ceftriaxone + metronidazole or rifampin (6-8 wk therapy)
  - revise antibiotics when C&S known
- anti-convulsants (1-2 yr)
- follow-up CT is critical (do weekly initially, more frequent if condition deteriorates)

Prognosis
- mortality with appropriate therapy ~10%, permanent deficits in ~50%

<td>Medical: decrease BP, control ICP Surgical: craniotomy</td>
<td>Poor: 44% mortality due to cerebral herniation</td>
</tr>
</tbody>
</table>
Extradural ("Epidural") Hematoma

Etiology
• temporal-parietal skull fracture: 85% are due to ruptured middle meningeal artery; remainder of cases are due to bleeding from middle meningeal vein, dural sinus, or bone/diploic veins

Epidemiology
• young adult, M>F = 4:1; rare before age 2 or after age 60
• 1-4% of traumatic head injuries

Clinical Features
• classic sequence (seen in <30%): post-traumatic reduced LOC, a lucid interval of several hours, then obtundation, hemiparesis, ipsilateral pupillary dilatation, and coma
• signs and symptoms depend on severity but can include H/A, N/V, amnesia, altered LOC, aphasia, seizures, HTN, and respiratory distress
• deterioration can take hours to days

Investigations
• CT without contrast: “lenticular-shaped” usually limited by suture lines but not limited by dural attachments

Treatment
• admission, close neurological observation with serial CT indicated if all of the following are present:
  ▪ small volume clot, minimal midline shift (MLS <5 mm), GCS >8, no focal deficit
  ▪ otherwise, craniotomy to evacuate clot, follow up CT
  ▪ mannitol pre-operative if elevated ICP or signs of brain herniation

Prognosis
• good with prompt management, as the brain is often not damaged
• worse prognosis if bilateral Babinski or decerebration pre-operative
• death is usually due to respiratory arrest from uncal herniation (injury to the midbrain)

Subdural Hematoma

ACUTE SUBDURAL HEMATOMA
• 1-2 d after bleeding onset

Etiology
• rupture of vessels that bridge the subarachnoid space (e.g. cortical artery, large vein, venous sinus) or cerebral laceration

Risk Factors
• trauma, acceleration-deceleration injury, anticoagulants, alcohol, cerebral atrophy, infant head trauma (see Pediatrics)

Clinical Features
• no lucid period, signs and symptoms can include altered LOC, pupillary irregularity, hemiparesis

Investigations
• CT: hyperdense concave “crescentic” mass, crossing suture lines

Treatment
• craniotomy if clinically symptomatic, if hematoma >1 cm thick, or if MLS >5 mm (optimal if surgery <4 h from onset); otherwise observe with serial imaging

Prognosis
• poor overall since the brain parenchyma is often injured (mortality range is 50-90%, due largely to underlying brain injury)
• prognostic factors: initial GCS and neurologic status, post-operative ICP

CHRONIC SUBDURAL HEMATOMA
• ≥15 d after bleeding onset

Use of Drains vs. No Drains After Burr-Hole Evacuation of Chronic Subdural Hematoma: A Randomized Control Trial
Lancet 2009;374:1067-1073
Purpose: To examine the effect of drains on recurrence rates of chronic subdural hematoma (SDH), and clinical outcomes.
Study: RCT with 268 patients ≥18 yr of age with chronic SDH. Half of the patients were randomly assigned to receive a subdural drain and the other half no drain after evacuation.
Results: Recurrence occurred in 9.3% of people with a drain and 24% without (p=0.003; 95% CI 0.14-0.70). Although rates of complications were the same between the study groups, mortality at 6 mo was 8.6% in the group receiving a drain and 18.1% in the group not receiving a drain (p=0.042; 95% CI 0.1-0.99).
Conclusions: Use of drains after burr-hole drainage of chronic SDH is safe and associated with a reduced recurrence and mortality at 6 mo.
Etiology
- many start out as acute SDH
- blood within the subdural space evokes an inflammatory response:
  - fibroblast invasion of clot and formation of neomembranes within days → growth of neocapillaries → fibrinolysis and liquefaction of blood clot (forming a hygroma)
- course is determined by the balance of rebleeding from neomembranes and resorption of fluid

Risk Factors
- older, alcoholics, patients with CSF shunts, anticoagulants, coagulopathies

Clinical Features
- often due to minor injuries or no history of injury
- may present with minor H/A, confusion, language difficulties, TIA-like symptoms, symptoms of raised ICP ± seizures, progressive dementia, gait problem
- obtundation disproportionate to focal deficit; “the great imitator” of dementia, tumors

Investigations
- CT: hypodense (liquefied clot), crescentic mass

Treatment
- seizure prophylaxis only if post-traumatic seizure
- reverse coagulopathies
- burr hole drainage of liquefied clot indicated if symptomatic or thickness >1 cm; craniotomy if recurs more than twice

Prognosis
- good overall as brain usually undamaged, but may require repeat drainage

Cerebrovascular Disease

Ischemic Cerebral Infarction (80%)
- embolic, thrombosis of intracerebral arteries, vasculitis, hypercoagulability, etc.
  (see Neurology)

Intracranial Hemorrhage (20%)
- SAH, spontaneous ICH, IVH

Hemicraniectomy in Older Patients with Extensive Middle-Cerebral-Artery Stroke
NEJM 2014;370:1091-1100
Purpose: To determine if early decompressive hemicraniectomy reduces mortality among patients >60 yr.
Study: 112 patients >60 yr (median age 70 yr) with malignant MCA infarction randomly assigned to conservative ICU treatment vs. hemicraniectomy. Endpoint was survival without severe disability (modified Rankin scale score 0-4).
Results: The proportion of patients who survived without severe disability was 38% in the hemicraniectomy group and 18% in the control group (OR 2.91, 95% CI 1.06-7.49). Modified Rankin scale scores in hemicraniectomy vs. control group in terms of percentages of patients: 0-2 (0%, 0%), 3 or moderate disability (7%, 3%), 4 or moderate severe disability (32%, 15%), 5 or severe disability (21%, 13%) and 6 or death (31%, 70%). Infections were more frequent in the hemicraniectomy group and herniation more frequent in the control group.
Conclusions: Hemicraniectomy increased survival without severe disability among patients >60 yr with a malignant MCA infarction.
Subarachnoid Hemorrhage

Definition
- bleeding into subarachnoid space (intracranial vessel between arachnoid and pia)

Etiology
- trauma (most common)
- spontaneous
  - ruptured aneurysms (75-80%)
  - idiopathic (14-22%)
  - AVMs (4-5%)
- coagulopathies (iatrogenic or primary), vasculitides, tumors, cerebral artery dissections (<5%)

Epidemiology
- ~10-28/100,000 population/yr
- peak age 55-60, 20% of cases occur under age 45

Risk Factors
- HTN
- pregnancy/parturition in patients with pre-existing AVMs, eclampsia
- oral contraceptive pill
- substance abuse (cigarette smoking, cocaine, alcohol)
- conditions associated with high incidence of aneurysms (see Intracranial Aneurysms, NS21)

Clinical Features of Spontaneous SAH
- sudden onset (seconds) of severe "thunderclap" H/A usually following exertion and described as the "worst headache of my life" (up to 97% sensitive, 12-25% specific)
- N/V, photophobia
- meningismus (neck pain/stiffness, positive Kernig's and Brudzinski's sign)
- decreased LOC (due to either raised ICP, ischemia, seizure)
- focal deficits: cranial nerve palsies (CN III, IV), hemiparesis
- ocular hemorrhage in 20-40% (due to sudden raised ICP compressing central retinal vein)
- reactive HTN
- sentinel bleeds
  - represents undiagnosed SAH
  - SAH-like symptoms lasting <1 d ("thunderclap H/A")
  - may have blood on CT or LP
  - ~30-60% of patients with full blown SAH give history suggestive of sentinel bleed within past 3 wk
- differential diagnosis: sentinel bleed, dissection/thrombosis of aneurysm, venous sinus thrombosis, benign cerebral vasculitis, benign exertional H/A

Investigations
- non-contrast CT – for diagnosis of SAH
  - 98% sensitive within 12 h, 93% within 24 h; 100% specificity
  - may be negative if small bleed or presentation delayed several days
  - acute hydrocephalus, IVH, ICH, infarct or large aneurysm may be visible
- lumbar puncture (highly sensitive) – for diagnosis of SAH if CT negative but high suspicion:
  - elevated opening pressure (>18 cmH₂O)
  - bloody initially, xanthochromic supernatant with centrifugation ("yellow") by ~12 h, lasts 2 wk
  - RBC count usually >100,000/mm³ without significant drop from first to last tube (in contrast to traumatic tap)
  - elevated protein due to blood breakdown products
- four vessel cerebral angiography ("gold standard" for aneurysms)
  - demonstrates source of SAH in 80-85% of cases
  - angiogram negative SAH: repeat angiogram in 7-14 d, if negative ⇒ "perimesencephalic SAH"
- MRA and CTA: sensitivity up to 95% for aneurysms, CTA>MRA for smaller aneurysms and delineating adjacent bony anatomy

*Intact aneurysm
Figure 17. Diagnosis of SAH

- History of sudden severe headache
- Neurological assessment
- BP, LOC, Limb movements
- CT scan
- Stiff neck, Fundi
- Negative for blood
- Lumbar puncture
- CSF: clear, colorless, no microscopic blood
- CSF: blood ± xanthochromia
- D/C home
- Positive for blood and/or patient drowsy, unconscious, localizing neurological findings
- Refer to Neurosurgery
- CTA/MRA/angiography

Figure 18. Approach to SAH

**Treatment**
- admit to ICU or NICU
  - oxygen/ventilation prn
  - NPO, bed rest, elevate head of bed 30°, minimal external stimulation, neurological vitals q1h
  - aim to maintain sBP = 120-150 (balance of vasospasm prophylaxis, risk of re-bleed, risk of hypotension since CBF autoregulation impaired by SAH)
  - cardiac rhythm monitor, Foley prn, strict monitoring of ins and outs
- medications
  - IV NS with 20 mEq KCl/L at 125-150 cc/h
  - nimodipine 60 mg PO/NG q4h x 21 d for delayed cerebral ischemia neuroprotection; may discontinue earlier if patient is clinically well
  - seizure prophylaxis: levetiracetam (Keppra®) 500 mg PO/IV q12h x 1 wk
  - mild sedation prn

**Complications**
- vasospasm: vasoconstriction and permanent pathological vascular changes in response to vessel irritation by blood – can lead to delayed cerebral ischemia and death
  - onset: 4-14 d post-SAH, peak at 6-8 d; most commonly due to SAH, rarely due to ICH/IVH
  - clinical features (new onset ischemic deficit): confusion, decreased LOC, focal deficit (speech or motor e.g. pronator drift)
  - risk factors: large amount of blood on CT (high Fisher grade), smoking, increased age, HTN
  - “symptomatic” vasospasm in 20-30% of SAH patients
  - “radiographic” vasospasm in 30-70% of arteriograms performed 7 d following SAH
  - diagnosed clinically, and/or with transcranial Doppler (increased velocity of blood flow)
  - risk of cerebral infarct and death
  - treatment
    - hyperdynamic (“triple H”) therapy using fluids and pressors, usually after ruptured aneurysm has been clipped/coiled
    - direct vasodilation via angioplasty or intra-arterial verapamil for refractory cases
    - hydrocephalus (15-20%): due to blood obstructing arachnoid granules
    - can be acute or chronic, requires extraventricular drain (EVD) or shunt, respectively
    - neurogenic pulmonary edema

Calcium Antagonists for Aneurysmal Subarachnoid Hemorrhage
Cochrane DB Syst Rev 2007;3:CD000277

**Introduction:** This study looked to review the evidence in regards to whether calcium antagonists improve the outcome in patients with aneurysmal subarachnoid hemorrhage.

**Methods/Population:** The review included 3,361 patients presenting with aneurysmal subarachnoid hemorrhage from 16 RCTs comparing treatment with calcium antagonists vs. control from 1980 to March 2006.

**Results:** The results were based mainly on one large trial of oral nimodipine, which showed a RR of 0.67 (95% CI 0.55-0.81) and the evidence for other calcium agonists was not statistically significant.

**Conclusion:** The authors endorse the use of oral nimodipine in patients with aneurysmal subarachnoid hemorrhage.
• hyponatremia: due to cerebral salt wasting (increased renal sodium loss and ECFV loss), not SIADH
• diabetes insipidus
• cardiac: arrhythmia (>50% have ECG changes), MI, CHF

Prognosis
• 10-15% mortality before reaching hospital, overall 50% mortality (majority within first 2-3 wk)
• 30% of survivors have moderate to severe disability
• a major cause of mortality is rebleeding, for untreated aneurysms:
  ▪ risk of rebleed: 4% on first day, 15-20% within 2 wk, 50% by 6 mo
  ▪ if no rebleed by 6 mo, risk decreases to same incidence as unruptured aneurysm (2%)
  ▪ only prevention is early clipping or coiling of “cold” aneurysm
  ▪ rebleed risk for “perimesencephalic SAH” is approximately same as for general population

Intracerebral Hemorrhage

Definition
• hemorrhage within brain parenchyma, accounts for ~10% of strokes
• can dissect into ventricular system (IVH) or through cortical surface (SAH)

Etiology
• HTN (usually causes bleeds at putamen, thalamus, pons, and cerebellum)
• hemorrhagic transformation (reperfusion post stroke, surgery, strenuous exercise, etc.)
• vascular anomalies
  ▪ aneurysm, AVMs, and other vascular malformations (see Vascular Malformations, NS22)
  ▪ venous sinus thrombosis
• arteriopathies (cerebral amyloid angiopathy, lipohyalinosis, vasculitis)
• tumors (1%): often malignant (e.g. GBM, lymphoma, metastases)
• drugs (amphetamines, cocaine, alcohol, anticoagulants, etc.)
• coagulopathy (iatrogenic, leukemia, TTP, aplastic anemia)
• CNS infections (fungal, granulomas, herpes simplex encephalitis)
• post trauma (immediate or delayed, frontal and temporal lobes most commonly injured via coup-contrecoup mechanism)
• eclampsia
• post-operative (post-carotid endarterectomy cerebral reperfusion, craniotomy)
• idiopathic

Epidemiology
• 12-15 cases/100,000 population/yr

Risk Factors
• increasing age (mainly >55 yr)
• male gender
• HTN
• Black/Asian > Caucasian
• previous CVA of any type (23x risk)
• both acute and chronic heavy alcohol use; cocaine, amphetamines
• liver disease
• anticoagulants

Clinical Features
• TIA-like symptoms often precede ICH, can localize to site of impending hemorrhage
• gradual onset of symptoms over minutes-hours, usually during activity
• H/A, N/V, and decreased LOC are common
• specific symptoms/deficits depend on location of ICH

Investigations
• hyperdense blood on non-contrast CT
• CTA routine, if spot sign demonstrated there is high likelihood of clot growth

Treatment
• medical
  ▪ decrease MAP to pre-morbid level or by ~20% (target BP 140/90)
  ▪ check PTT/INR, and correct coagulopathy
  ▪ control raised ICP (see Intracranial Pressure Dynamics, NS4)
  ▪ levetiracetam/phenytoin for seizure prophylaxis
  ▪ follow electrolytes (SIADH common)
  ▪ angiogram to rule out vascular lesion unless >45 yr, known HTN, and putamen/thalamic/posterior fossa ICH (yield ~0%)
• surgical
  ▪ craniotomy with evacuation of clot, treatment of source of ICH (i.e. AVM, tumor, cavernoma), ventriculostomy to treat hydrocephalus
• indications
  ▪ symptoms of raised ICP or mass effect
  ▪ rapid deterioration (especially if signs of brainstem compression)
  ▪ favorable location (e.g. cerebellar, non-dominant hemisphere)
  ▪ young patient (<50 yr)
  ▪ if tumor, AVM, aneurysm, or cavernoma suspected (resection or clip to decrease risk of rebleed)
• contraindications
  ▪ small bleed: minimal symptoms, GCS >10
  ▪ poor prognosis: massive hemorrhage (especially dominant lobe), low GCS/coma, lost brainstem function
  ▪ medical reasons (e.g. very elderly, severe coagulopathy, difficult location [e.g. basal ganglia, thalamus])

Prognosis
• 30-d mortality rate 44%, mostly due to cerebral herniation
• rebleed rate 2-6%, higher if HTN poorly controlled

### Intracranial Aneurysms

#### Epidemiology
- prevalence 1-4% (20% have multiple)
- F>M; age 35-65 yr

#### Risk Factors
- autosomal dominant polycystic kidney disease (15%)
- fibromuscular dysplasia (7-21%)
- AVMs
- connective tissue diseases (Ehlers-Danlos, Marfan)
- family history
- bacterial endocarditis
- Osler-Weber-Rendu syndrome (hereditary hemorrhagic telangiectasia)
- atherosclerosis and HTN
- trauma

#### Types (for location, see Figure 4, NS3)
- saccular (berry)
  ▪ most common type
  ▪ located at branch points of major cerebral arteries (Circle of Willis)
  ▪ 85-95% in carotid (anterior) system, 5-15% in verteobasilar (posterior) circulation
- fusiform
  ▪ atherosclerotic
  ▪ more common in verteobasilar system, rarely rupture
- infectious
  ▪ secondary to any infection of vessel wall, 20% multiple
  ▪ 60% Streptococcus and Staphylococcus
  ▪ 3-15% of patients with bacterial endocarditis

#### Table 9. Five Year Cumulative Rupture Risk in Unruptured Aneurysms Based on Size and Location

</tbody>
</table>

#### Clinical Presentation
- rupture (90%), most often SAH, but 30% ICH, 20% IVH, 3% subdural bleed
- sentinel hemorrhage (“thunderclap H/A”) ⇒ requires urgent clipping/coiling to prevent catastrophic bleed
- mass effect (giant aneurysms)
  ▪ internal carotid or anterior communicating aneurysm may compress:
    ▪ the pituitary stalk or hypothalamus causing hypopituitarism
    ▪ the optic nerve or chiasma producing a visual field defect
  ▪ basilar artery aneurysm may compress midbrain, pons (limb weakness), or CN III
  ▪ posterior communicating artery aneurysm may produce CN III palsy

#### Long-Term, Serial Screening for Intracranial Aneurysms in Individuals with a Family History of Aneurysmal Subarachnoid Hemorrhage: A Cohort Study

- **Objective:** To examine the yield of long-term serial screening for intracranial aneurysms for individuals with a positive family history of subarachnoid hemorrhage (aSAH) and to calculate the life-time aSAH risk for first-degree relatives with aSAH

- **Methods:** Serial CTA from age 16-18 to 65-70 yr. After a negative screen, individuals were advised to contact the clinic in 5 yr for follow up.

- **Results:** Aneurysms were identified in 11% of individuals at first screening (n=458), 8% at second screening (n=261), 3% at third screening (n=128), and 5% at fourth screening (n=63). After a negative screen, individuals were advised to contact the clinic in 5 yr for follow up.

- **Conclusions:** The yield of long-term screening in individuals with a family history of aSAH is substantially up to and after 10 yr of follow-up and two initial negative screens.
intradural aneurysms (CN III, IV, V1, V2, VI)
- distal embolization (e.g. amaurosis fugax)
- seizures
- H/A (without hemorrhage)
- incidental CT or angiography finding (asymptomatic)

**Investigations**
- CT angiogram (CTA), magnetic resonance angiography (MRA), cerebral angiogram

**Treatment**
- ruptured aneurysms
  - overall trend towards better outcome with early surgery or coiling (48-96 h after SAH)
  - treatment options: surgical placement of clip across aneurysm neck, trapping (clipping of proximal and distal vessels), thrombosing using Guglielmi detachable coils (coiling), wrapping (last resort)
  - choice of surgery vs. coiling not yet well defined, consider location, size, shape, and tortuosity of the aneurysm, patient comorbidities, age, and neurological condition. In general:
    - coiling: posterior > anterior circulation, deep/eloquent location, basilar artery bifurcation/apex, older age, presence of comorbidities, presence of vasospasm
    - clipping: superficial > deep, broad aneurysmal base, branching arteries at the aneurysm base, tortuosity/atherosclerosis of afferent vessels, dissection, hemotoma, acute brainstem compression
  - unruptured aneurysms
    - average 1% annual risk of rupture: risk dependent on size and location of aneurysm
    - no clear evidence on when to operate: need to weigh life expectancy
    - risk of morbidity/mortality of SAH (20%-50%) vs. surgical risk (2%-5%)
    - generally treat unruptured aneurysms >10 mm
    - consider treating when aneurysm 7-9 mm in middle-aged, younger patients or patients with a family history of aneurysms
    - follow smaller aneurysms with serial angiography

**Vascular Malformations**

**Types**
- arteriovenous malformations (AVMs)
- cavernous malformations (= cavernomas, cavernous hemangiomas/angiomas)
- venous angioma
- capillary telangiectasias
- arteriovenous fistula (AVF) (carotid-cavernous fistula, dural AVF, vein of Galen aneurysm)
- “angiographically occult vascular malformations” (any type, 10% of malformations)

**Arteriovenous Malformations**

**Definition**
- tangle of abnormal vessels/arteriovenous shunts, with no intervening capillary beds or brain parenchyma; usually congenital

**Epidemiology**
- prevalence ~0.14%, M:F = 2:1, average age at diagnosis = 33 yr
- 15-20% of patients with hereditary hemorrhagic telangiectasia (Osler-Weber-Rendu syndrome) will have cerebral AVMs

**Clinical Features**
- hemorrhage (40-60%): small AVMs are more likely to bleed due to direct high pressure AV connections
- seizures (50%): more common with larger AVMs
- mass effect
- focal neurological signs secondary to ischemia (high flow – “steal phenomena”)
- localized H/A, increased ICP
- bruit (especially with dural AVMs)
- may be asymptomatic (“silent”)

**Investigations**
- MRI (flow void), MRA
- angiography (7% will also have one or more associated aneurysms)

**Treatment**
- decreases risk of future hemorrhage and seizure
  - surgical excision is treatment of choice
  - SRS (stereotactic radiosurgery) is preferred for small (<3 cm) or very deep lesions
  - endovascular embolization (glue, balloon) can be curative (5%) or used as adjuvant to surgery or SRS in larger lesions
  - conservative (e.g. palliative embolization, seizure control if necessary)
Prognosis
- 10% mortality, 30-50% morbidity (serious neurological deficit) per bleed
- risk of major bleed in untreated AVMs: 2-4% per year

Cavernous Malformations
- benign vascular hamartoma consisting of irregular sinusoidal vascular channels located within the brain without intervening neural tissue or associated large arteries/veins
- several genes now described: CCM1, CCM2, CCM3
- prevalence of 0.1-0.2%, both sporadic and hereditary forms described

Clinical Features
- seizures (60%), progressive neurological deficit (50%), hemorrhage (20%), H/A
- often an incidental finding
- hemorrhage risk less than AVM, usually minor bleeds

Investigations
- T2WI MRI (non-enhancing; see Figure 19) gradient echo sequencing (best for diagnosis)

Treatment
- surgical excision
  - only appropriate for symptomatic lesions that are surgically accessible (supratentorial lesions are less likely to bleed than infratentorial lesions)

EXTRACRANIAL PATHOLOGY

Approach to Limb/Back Pain
- see Orthopedics

Extradural Lesion

Figure 20. Vascular supply of spinal cord
Root Compression

Differential Diagnosis
- herniated disc
- neoplasm (neurofibroma, schwannoma)
- synovial cyst, abscess
- hypertrophic bone/spur

Cervical Disc Syndrome

Etiology
- nucleus pulposus herniates through annulus fibrosus and impinges upon nerve root, most commonly at C6-C7 (C7 root)

Clinical Features
- pain in arm follows nerve root distribution, worse with neck extension, ipsilateral rotation, and lateral flexion (all compress the ipsilateral neural foramen)
- LMN signs and symptoms
- central cervical disc protrusion causes myelopathy as well as nerve root deficits

Investigations
- if red flags: C-spine x-ray, CT, MRI (imaging of choice)
- only consider EMG, nerve conduction studies if diagnosis uncertain and presenting more as peripheral nerve issue.

Treatment
- conservative
  - no bedrest unless severe radicular symptoms
  - activity modification, patient education (reduce sitting, lifting)
  - physiotherapy, exercise programs focus on strengthening core muscles
  - analgesics, NSAIDs are more efficacious
  - avoid cervical manipulation, like traction
- surgical indications
  - anterior cervical discectomy is usual approach
  - intractable pain despite adequate conservative treatment for >3 mo
  - progressive neurological deficit

Prognosis
- 95% improve spontaneously in 4-8 wk

Cervical Stenosis (Cervical Spondylosis)

Definition
- cervical spondylosis is chronic disc degeneration and associated facet arthropathy
- resultant syndromes include mechanical neck pain, radiculopathy, myelopathy, and combinations

Epidemiology
- typically begins at age 40-50, M>E, most commonly at the C5-C6 > C6-C7 levels

Pathogenesis
- any of: disc degeneration/herniation, osteophyte formation, ossification, and hypertrophy of ligaments
- pathophysiology includes static compression, dynamic compression, and vascular compromise

Clinical Features
- insidious onset of mechanical neck pain exacerbated by excess vertebral motion (particularly rotation and lateral bending with a vertical compressive force – Spurling’s test)
- occipital H/A is common
- radiculopathy may involve 1 or more roots, and symptoms include neck, shoulder and arm pain, paresthesias and numbness
• cervical myelopathy may be characterized by weakness (upper > lower extremity), decreased dexterity, and sensory changes
• UMN findings such as hyperreflexia, clonus, and Babinski reflex may be present
• most worrisome complaint is lower extremity weakness (corticospinal tracts)
• myelopathy may be associated with funicular pain, characterized by burning and stinging ± Lhermitte’s sign (lightning-like sensation down the back with neck flexion)

Investigations
• x-ray of cervical spine ± flexion/extension (alignment, fractures)
• MRI most useful for determination of compression of the neural element
• CT is only used for better determination of bony anatomy (i.e. OPLL)
• EMG/nerve conduction studies reserved for peripheral nerve investigation

Treatment
• decompression and stabilization need to be included in the management
• NSAIDs, moist heat, strengthening and range of motion exercises, analgesics, cervical collar, cervical traction
• surgical indications: myelopathy with motor impairment, progressive neurologic impairment, intractable pain

Lumbar Disc Syndrome

Etiology
• posterolaterally herniated disc compressed nerve root exiting BELOW the level of the disc or the traversing nerve root
• far lateral disc herniation compressed nerve root AT the level of the disc or the exiting nerve root
• central herniation causes cauda equina or lumbar stenosis (neurogenic claudication)

Clinical Features
• initialy back pain, then leg pain > back pain
• limited back movement (especially forward flexion) due to pain
• motor weakness, dermatomal sensory changes, decreased reflexes
• exacerbation with valsalva; relief with flexing the knee or thigh
• nerve root tension signs
  ▪ straight leg raise (SLR, Lasegue’s test) or crossed SLR (pain should occur at less than 60 degrees) suggests L5, S1 root involvement
  ▪ femoral stretch test suggests L2, L3, or L4 root involvement

Investigations
• MRI is modality of choice
• x-ray spine (only to rule out other lesions), CT (bony anatomy)
• myelogram and post-myelogram CT (only if MRI is contraindicated)

Treatment
• conservative (same as cervical disc disease)
• surgical indications
  ▪ same as cervical disc + cauda equina syndrome

Prognosis
• 95% improve spontaneously within 4 to 8 wk
• do not follow patients with serial MRIs; clinical status is more important at guiding management

Figure 21. T2-weighted MRI of lumbar disc herniation

Lumbar Disc Herniation: What are Reliable Criterions Indicative for Surgery?
Orthopedics 2009;32:589-597
1) The only clear indication for early surgery in LDH is cauda equina syndrome.
2) Pain may also be an indication for surgery. If conservative treatment is intended, it should be considered for at least 2 mo but not beyond 1 yr if the patient shows minimal improvement, since the beneficial effects of surgery will diminish after this period.
3) The type of herniation on MRI is not relevant to the decision of whether or not to operate on patients with LDH.
4) Although paresis is often a red flag symptom for patients with LDH, neither the magnitude nor the duration of paresis should be used as an indication for early surgery.

Magnetic Resonance Imaging in Follow-Up Assessment of Sciatica
NEJM 2013;369:999-1002
Background: Follow-up MRI is a controversial method for monitoring sciatica in patients with known lumbar disc herniation.
Methods: Participants (n=293) were recruited from a simultaneous, parallel, randomized study comparing surgery and conservative care for sciatica (the Sciatica Trial). MRI and clinical assessment were undertaken pre-treatment and 1 yr post-treatment randomization to visualize disc herniation and evaluate outcome.
Results: At 1 yr, disc herniation was visible in 35% with a favorable outcome (complete, or nearly complete symptom resolution) and in 33% with an unfavorable outcome (p=0.70). A favorable outcome was reported in 89% of patients with disc herniation and 83% without disc herniation (p=0.70).
Conclusions: Anatomical abnormalities visible on repeated MRI 1 yr after treatment for sciatica due to lumbar disc herniation could not distinguish patients with resolution of their symptoms from patients still experiencing symptoms.

</tbody>
</table>

### Cauda Equina Syndrome

**Etiology**
- compression or irritation of lumbosacral nerve roots below conus medullaris (below L2 level)
- decreased space in the vertebral canal below L2
- common causes: herniated disc ± spinal stenosis, vertebral fracture, and tumor

**Clinical Features**
- usually acute (develops in less than 24 h); rarely subacute or chronic
- motor (LMN signs)
  - weakness/paraparesis in multiple root distribution
  - reduced deep tendon reflexes (knee or ankle)
- autonomic
  - urinary retention (or overflow incontinence) and/or fecal incontinence due to loss of anal sphincter tone
  - sensory
    - low back pain radiating to legs (sciatica) aggravated by Valsalva maneuver and by sitting; relieved by lying down
    - bilateral sensory loss or pain: depends on the level affected
    - saddle area (S2-S5) anesthesia
    - sexual dysfunction (late finding)

**Investigations**
- urgent MRI to confirm compression of S2-S3-S4 nerve root by a large disc herniation
- post-void residual very helpful to determine if true retention is present; volumes controversial but anything over 250 cc in a healthy individual is cause for concern

**Treatment**
- surgical decompression (<48 h) to preserve bowel, bladder, and sexual function, and/or to prevent progression to paraplegia

**Prognosis**
- markedly improves with surgical decompression
- recovery correlates with function at initial presentation: if patient is ambulatory, likely to continue to be ambulatory; if unable to walk, unlikely to walk after surgery

### Lumbar Spinal Stenosis

**Etiology**
- congenital narrowing of spinal canal combined with degenerative changes (herniated disc, hypertrophied facet joints, and ligamentum flavum)

**Clinical Features**
- gradually progressive back and leg pain with standing and walking that is relieved by sitting or lying down (neurogenic claudication – 60% sensitive)
- neurologic exam may be normal, including straight leg raise test

**Investigations**
- MRI is the optimal investigation to confirm and localize the level of stenosis (unlike nerve root compression which can be localized with clinical exam)

**Treatment**
- conservative: NSAIDs, analgesia
- surgical: laminectomy with root decompression (the role of fusion may need to be considered if the amount of bone removed with the laminectomy results in de-stabilization)
Neurogenic Claudication

Etiology
- ischemia of lumbosacral nerve roots secondary to vascular compromise and increased demand from exertion, often associated with lumbar stenosis

Clinical Features
- dermatomal pain/paresthesia/weakness of buttock, hip, thigh, or leg initiated by standing or walking
- slow relief with postural changes (sitting >30 min), NOT simply exertion cessation
- induced by variable degrees of exercise or standing
- may be elicited with lumbar extension, but may not have any other neurological findings, no signs of vascular compromise (e.g. ulcers, poor capillary refill, etc.)

Investigations
- bicycle test may help distinguish neurogenic claudication (NC) from vascular claudication (the waist-flexed individuals on the bicycle with NC can last longer)

Treatment
- same as for lumbar spinal stenosis

Intradural Intramedullary Lesions

Syringomyelia (Syrinx)

Definition
- cystic cavitation of the spinal cord
- presentation is highly variable, usually progresses over months to years
- initially pain, weakness, later atrophy and loss of pain and temperature sensation

Etiology
- 70% are associated with Chiari I malformation, 10% with basilar invagination
- post-traumatic
- tumor
- tethered cord

Clinical Features
- nonspecific features for any intramedullary spinal cord pathology
  - initially pain, weakness, atrophy, loss of pain and temperature in upper extremities (central syrinx) with progressive myelopathy over years
  - sensory loss with preserved touch and proprioception in a band-like distribution at the level of cervical syrinx
  - sensory loss with preserved touch and proprioception in a band-like distribution at the level of cervical syrinx
  - dysesthetic pain often occurs in the distribution of the sensory loss
  - LMN arm/hand weakness or wasting
  - painless neuropathic arthropathies (Charcot’s joints), especially in the shoulder and neck due to loss of pain and temperature sensation

Investigations
- MRI is best method, myelogram with delayed CT

Treatment
- treat underlying cause (e.g. posterior fossa decompression for Chiari I, surgical removal of tumor if causing a syrinx)
- rarely does the syrinx need to be shunted, only when progressive and size allows for insertion of tube

Spinal Cord Syndromes

- spinal cord injury impairment classified according to ASIA score
- ASIA A: complete, no motor/sensory below neurological level including S4/5
- ASIA B: incomplete, sensory but not motor function preserved below neurological level including S4/5
• ASIA C: incomplete, motor function preserved below neurological level, and more than half of the key muscles below neurological level have a muscle grade <3
• ASIA D: incomplete, motor function preserved below neurological level, and more than half of the key muscles below neurological level have a muscle grade 3 or more
• ASIA E: normal motor and sensory function

Complete Spinal Cord Lesion
• bilateral loss of motor/sensory and autonomic function at ≥4 segments below lesion/injury, with UMN signs
• about 3% of patients with complete injuries will develop some recovery within 24 h, beyond 24 h, no distal function will recover

Incomplete Spinal Cord Lesion
• any residual function at ≥4 segments below lesion
• signs include sensory/motor function in lower limbs and “sacral sparing” (perianal sensation, voluntary rectal sphincter contraction)

Table 13. Comparison Between Incomplete Spinal Cord Lesion Syndromes

Peripheral Nerves

• see Neurology, N35

Seddon's Classification of Peripheral Nerve Injury
• class I: neurapraxia – axon structurally intact but fails to function; recovery within hours to months (average 6-8 wk)
• class II: axonotmesis – axon and myelin sheath disrupted but endoneurium and supporting structures intact ➔ Wallerian degeneration of axon segment distal to injury ➔ spontaneous axonal recovery at 1 mm/d, max at 1-2 yr
• class III: neurotmesis – nerve completely transected, need surgical repair for possibility of recovery
• etiologies: ischemia, nerve entrapment – nerve compressed by nearby anatomic structures, often secondary to localized, repetitive mechanical trauma with additional vascular injury to nerve

Investigations
• neurological exam (power, sensation, reflexes), localization via Tinel’s sign (paresthesias elicited by tapping along the course of a nerve)
• electrophysiological studies (EMG, nerve conduction study) may be helpful in assessing nerve integrity and monitoring recovery, not helpful until 2-3 wk post-injury
• labs: blood work, CSF
• imaging: C-spine, chest/bone x-rays, myelogram, CT, magnetic resonance neurography
• angiogram if vascular damage is suspected

Treatment
• early neurosurgical consultation if injury is suspected
• entrapment
  • conservative: prevent repeated stress/injury, physiotherapy, NSAIDs, local anesthesia/steroid injection
  • surgical: nerve decompression ± transposition for progressive deficits, muscle weakness/atrophy, failure of medical management
• stretch/contusion
  • follow-up clinically for recovery; exploration if no recovery in 3 mo
  • axonotmesis
    • if no evidence of recovery, resect damaged segment

- prompt physical therapy and rehabilitation to increase muscle function, maintain joint range of motion, and maximize return of useful function
- recovery usually incomplete
- neurotmesis
- surgical repair of nerve sheath unless known to be intact (suture nerve sheaths directly if ends approximate or nerve graft (usually sural nerve))
- clean laceration: early exploration and repair
- contamination or associated injuries: tag initially with nonabsorbable suture, reapproach within 10 d

Complications
- neuropathic pain: with neuraoma formation
- complex regional pain syndrome: with sympathetic nervous system involvement

SPECIALTY TOPICS

Neurotrauma

Trauma Management (see Emergency Medicine, ER7)

Indications for Intubation in Trauma
1. depressed LOC (patient cannot protect airway): usually GCS ≤ 8
2. need for hyperventilation
3. severe maxillofacial trauma; patency of airway is doubtful
4. need for pharmacologic paralysis for evaluation or management
   - if basilar skull fracture suspected, avoid nasotracheal intubation as may inadvertently enter brain
   - note: intubation prevents patient’s ability to verbalize for determining GCS

Trauma Assessment

INITIAL MANAGEMENT

ABCs of Trauma Management
- see Emergency Medicine, ER2

NEUROLOGICAL ASSESSMENT

Mini-History
- period of LOC, post-traumatic amnesia, loss of sensation/function, type of injury/accident

Neurological Exam
- GCS
- head and neck (lacerations, bruises, basilar skull fracture signs, facial fractures, foreign bodies)
- spine (pulpable deformity, midline pain/tenderness)
- eyes (pupillary size and reactivity)
- brainstem (breathing pattern, CN palsies)
- cranial nerve exam
- motor exam, sensory exam (only if GCS is 15), reflexes
- sphincter tone
- record and repeat neurological exam at regular intervals

Investigations
- spinal injury precautions (cervical collar) are continued until C-spine is cleared
- C/EL-spine x-rays
  - AP, lateral, odontoid views for C-spine (must see from C1 to T1; swimmer’s view if necessary) or CT
  - rarely done: oblique views looking for pars interarticularis fracture ("Scottie dog" sign)
- CT head and upper C-spine (whole C-spine if patient unconscious) look for fractures, loss of mastoid or sinus air spaces, blood in cisterns, pneumocephalus
- cross and type, ABG, CBC, drug screen (especially alcohol)
- chest and pelvic x-ray as indicated

TREATMENT

Treatment for Minor Head Injury
- observation over 24-48 h
- wake every hour
- judicious use of sedatives or pain killers during monitoring period

Glasgow Coma Scale

Best response for each component recorded individually (e.g. E3V5M5)

>99% (95% CI 0.99-1.00 for both). The negative predictive value of a normal CT scan was 100% (95% CI 0.96-1.00) and accuracy was not affected by the global severity of injury, CT slice thickness, or study quality.

Sensitivity and specificity for modern CT were both >99.9% (95% CI 0.99-1.00). The negative predictive value of a normal CT scan was 100% (95% CI 0.96-1.00) and accuracy was not affected by the global severity of injury, CT slice thickness, or study quality.

Conclusions: CT alone is sufficient to detect unstable cervical spine injuries in trauma patients and adjacent imaging is unnecessary with a negative CT scan result. Consequently, if a CT scan is negative for acute injury, the cervical collar may be removed from obtunded or intubated trauma patients.
Treatment for Severe Head Injury (GCS ≤8)
- clear airway and ensure breathing (if GCS ≤8, intubate)
- secure C-spine
- maintain adequate BP
- monitor for clinical deterioration
- monitor and manage increased ICP if present (see Herniation Syndromes, NS6)

Admission required if:
- skull fracture (indirect signs of basal skull fracture, see Head Injury)
- confusion, impaired consciousness, concussion with >5 min amnesia
- focal neurological signs, extreme H/A, vomiting, seizures
- unstable spine
- use of alcohol
- poor social support

Head Injury

Epidemiology
- M:F = 2-3:1

Pathogenesis
- acceleration/deceleration: contusions, subdural hematoma, axon and vessel shearing/mesencephalic hematoma
- impact: skull fracture, concussion, epidural hematoma
- penetrating: worse with high velocity and/or high missile mass
  - low velocity: highest damage to structures on entry/exit path
  - high velocity: highest damage away from missile tract

Scalp Injury
- rich blood supply
- considerable blood loss (vessels contract poorly when ruptured)
- minimal risk of infection due to rich vascularity

Skull Fractures
- depressed fractures: double density on skull x-ray (outer table of depressed segment below inner table of skull), CT with bone window is gold standard
- simple fractures (closed injury): no need for antibiotics, no surgery
- compound fractures (open injury): increased risk of infection, surgical debridement within 24 h is necessary
  - internal fractures into sinuses may lead to meningitis, pneumocephalus
  - risk of operative bleed may limit treatment to antibiotics
- basal skull fractures: not readily seen on x-ray, rely on clinical signs
  - retroauricular ecchymoses (Battle’s sign)
  - periorbital ecchymoses (raccoon eyes)
  - hemotympanum
  - CSF rhinorrhea, otorrhea (suspect CSF if halo or target sign present); suspect with Lefort II/III midface fracture

Cranial Nerve Injury
- most traumatic causes of cranial nerve injury do not warrant surgical intervention
- surgical intervention
  - CN II: local eye/orbit injury
  - CN III, IV, VI: if herniation secondary to mass
  - CN VIII: repair of ossicles
- CN injuries that improve
  - CN I: recovery may occur in a few months; most do not improve
  - CN III, IV, VI: majority recover
  - CN VII: recovery with delayed lesions
  - CN VIII: vestibular symptoms improve over weeks, deafness usually permanent (except when resulting from hemotympanum)

Arterial Injury
- e.g. carotid-cavernous (C-C) fistula, carotid/vertebral artery dissection

Intracranial Bleeding
- see Blood, NS15 and Cerebrovascular Disease, NS17

The Canadian CT Head Rule for Patients with Minor Head Injury
Lancet 2001;357:1391-1396

CT Head is only required for patients with minor head injuries with any one of the following:

High Risk (for neurological intervention)
- GCS score <15 at 2 h after injury.
- Suspected open or depressed skull fracture.
- Any sign of basal skull fracture (hemotympanum, “raccoon” eyes, cerebrospinal fluid otorrhea/rhinorrhea, Battle’s sign).
- Vomiting ≥2 episodes.
- Age ≥65 yr.

Medium Risk (for brain injury on CT)
- Amnesia after impact >30 min.
- Dangerous mechanism (pedestrian struck by motor vehicle, occupant ejected from motor vehicle, fall from height >3 feet or five stairs).

Minor Head Injury is defined as witnessed loss of consciousness, definite amnesia, or witnessed disorientation in a patient with a GCS score of 13-15.
Brain Injury

Primary Impact Injury
- mechanism of injury determines pathology: penetrating injuries, direct impact
  - low velocity: local damage
  - high velocity: distant damage possible (due to wave of compression), concussion
- concussion: a trauma-induced alteration in mental status
  - American Academy of Neurology (AAN) Classification
  - no parenchymal abnormalities on CT
- coup (damage at site of blow) and contrecoup (damage at opposite site of blow)
  - acute decompression causes cavitation followed by a wave of acute compression
- contusion (hemorrhagic)
  - high density areas on CT ± mass effect
  - commonly occurs with brain impact on bony prominences (inferior frontal lobe, pole of temporal lobe)
- diffuse axonal injury/shearing
  - wide variety of damage results
  - may tear blood vessels (hemorrhagic foci)
  - often the cause of decreased LOC if no space-occupying lesion on CT

Secondary Pathologic Processes
- same subsequent biochemical pathways for each traumatic etiology
- delayed and progressive injury to the brain due to
  - high glutamate release $\rightarrow$ NMDA receptor activation $\rightarrow$ cytotoxic cascade
  - cerebral edema
  - intracranial hemorrhages
  - ischemia/infarction
  - raised ICP, intracranial HTN
  - hydrocephalus

Extracranial Conditions
- hypoxemia
  - due to trauma to the chest, upper airway, brainstem
  - extremely damaging to vulnerable brain cells
  - leads to ischemia, raised ICP
- hypercarbia
  - leads to raised ICP (secondary to vasodilation)
- systemic hypotension
  - caused by blood loss (e.g. ruptured spleen)
  - loss of cerebral autoregulation leads to decreased CPP, ischemia
- hyperpyrexia
  - leads to increased brain metabolic demands $\rightarrow$ ischemia
- fluid and electrolyte imbalance
  -iatrogenic (most common)
  -SIADH caused by head injury
  -diabetes insipidus (DI)
  -may lead to cerebral edema and raised ICP
- coagulopathy

Intracranial Conditions
- raised ICP due to traumatic cerebral edema OR traumatic intracranial hemorrhage

Brain Injury Outcomes
- mildly traumatic (GCS 13-15): post-concussive symptoms: H/A, fatigue, dizziness, nausea, blurred vision, diplopia, memory impairment, tinnitus, irritability, low concentration; 50% at 6 wk, 14% at 1 yr
- moderately traumatic (GCS 9-12): proportional to age (>40) and CT findings; 60% good recovery, 26% moderately disabled, 7% severely disabled, 7% vegetative/dead
- severe (GCS ≤8): difficult to predict, correlates with post-resuscitation GCS (especially motor) and age

Late Complications of Head/Brain Injury
- seizures: 5% of head injury patients develop seizures
  - incidence related to severity and location of injury (increased with local brain damage or intracranial hemorrhage)
  - post-traumatic seizure may be immediate, early, or late
  - presence of early (within first wk) post-traumatic seizure raises incidence of late seizures
• meningitis: associated with CSF leak from nose or ear
• hydrocephalus: acute hydrocephalus or delayed normal pressure hydrocephalus (NPH)

Spinal Cord Injury

- see Orthopedics, OR21 and Emergency Medicine, ER9

Neurogenic and Spinal Shock
1. neurogenic shock: hypotension that follows SCI (sBP usually ≤80 mmHg) caused by:
   - interruption of sympathetics (unopposed parasympathetics) below the level of injury
   - loss of muscle tone due to skeletal muscle paralysis below level of injury → venous pooling (relative hypovolemia)
   - blood loss from associated wounds (true hypovolemia)
2. spinal shock: transient loss of all neurologic function below the level of the spinal cord injury, causing flaccid paralysis and areflexia for variable periods

Whiplash-Associated Disorders
- definition: traumatic injury to the soft tissue structures in the region of the cervical spine due to hyperflexion, hyperextension, or rotational injury to the neck

Initial Management of SCI
- major causes of death in SCI are aspiration and shock
- the following patients should be treated as having a SCI until proven otherwise:
  - all victims of significant trauma
  - minor trauma patients with decreased LOC or complaints of neck or back pain, weakness, abdominal breathing, numbness/tingling, or priapism

Stabilization and Initial Evaluation in the Hospital
1. ABCs, immobilization (backboard/head strap), oxygenation, Foley catheter to urometer, temperature regulation
2. hypotension: maintain sBP >90 mmHg with pressors (dopamine), hydration, and atropine
   - DVT prophylaxis
3. monitor CBC/electrolytes
4. focused history (see Trauma Assessment, NS29)
5. spine palpation: point tenderness or deformity
6. motor level assessment (including rectal exam for voluntary anal sphincter contraction)
7. sensory level assessment: pinprick, light touch, and proprioception
8. evaluation of reflexes
9. signs of autonomic dysfunction: altered level of perspiration, bowel or bladder incontinence, priapism
10. radiographic evaluation
    - 3 views C-spine x-rays (AP, lateral, and odontoid) to adequately visualize C1 to C7-T1 junction
    - flexion-extension views to disclose occult instability
    - CT scan (bony injuries) typically most trauma centers use CT as the modality of choice for looking at fractures, very sensitive with the high resolution scanners
    - MRI mandatory if neurological deficits (soft tissue injuries)

Medical Management Specific to SCI
- option: methylprednisolone (given within 8 h of injury) this is controversial and you need to confer with Neurosurgery service
- ± decompression in acute, non-penetrating SCI

Fractures of the Spine

FRACTURES AND FRACTURE-DISLOCATIONS OF THE THORACIC AND LUMBAR SPINE
- assess ligamentous instability using flexion/extension x-ray views of C-spine ± MRI
- thoracolumbar spine unstable if 4/6 segments disrupted (3 columns divided into left and right)
  - anterior column: anterior half of vertebral body, disc, and anterior longitudinal ligament
  - middle column: posterior half of vertebral body, disc, and posterior longitudinal ligament
  - posterior column: posterior arch, facet joints, pedicle, lamina and supraspinous, interspinous, and ligamentum flavum ligaments

Types of Injury (Denis Classification)
- compression fracture
  - produced by flexion
• posterior ligament complex (supraspinous and interspinous ligaments, ligamentum flavum, and intervertebral joint capsules) remain intact
• fractures are stable but lead to kyphotic deformity

• burst fracture
  • stable: anterior and middle columns parted with bone retropulsed nearby
  • hallmark is pedicle widening on AP x-ray
  • spinal cord (seen on x-ray and CT), posterior column is uninjured
  • unstable: same as the stable but with posterior column disruption (usually ligamentous)

• flexion distraction injury
  • hallmark is pedicle widening on AP x-ray
  • spinal cord (seen on x-ray and CT); posterior column is uninjured
  • can be purely ligamentous, i.e. through PLL and disc

• fracture-dislocation
  • hallmark is pedicle widening on AP x-ray
  • spinal cord (seen on x-ray and CT); posterior column is uninjured
  • can be purely ligamentous, i.e. through PLL and disc

• flexion-rotation injury
  • hallmark is pedicle widening on AP x-ray
  • spinal cord (seen on x-ray and CT); posterior column is uninjured
  • can be purely ligamentous, i.e. through PLL and disc

Management of Thoracolumbar Injury
• management based on TLICS classification

FRACTURES OF THE CERVICAL SPINE

Types of Injury
• C1 vertebral fracture (Jefferson fracture)
  • vertical compression forces the occipital condyles of the skull down on the C1 vertebra (atlas), pushing the lateral masses of the atlas outward and disrupting the ring of the atlas
  • also can cause an occipital condylar fracture
• odontoid process fracture
  • causes C1 and odontoid of C2 to move independently of C2 body
  • this occurs because
  • normally C1 vertebra and odontoid of C2 are a single functional unit
  • alar and transverse ligaments on posterior aspect of odontoid most commonly remain intact following injury
  • patients often report a feeling of instability and present holding their head with their hands
• C2 vertebral fracture (hangman fracture, traumatic spondylolisthesis of axis):
  • bilateral fracture through the pars interarticularis of C2 with subluxation of C2 on C3
  • usually neurologically intact
• Clay-Shoveler fracture
  • avulsion of spinous process, usually C6 or C7

Imaging
• AP spine x-ray (open-mouth and lateral view), CT

Treatment
• immobilization in cervical collar or halo vest until healing occurs (usually 2-3 mo)
• Type II and III odontoid fractures
  • consider surgical fixation for comminution, displacement, or inability to maintain alignment with external immobilization
  • confirm stability after recovery with flexion-extension x-rays

Neurologically Determined Death

Definition
• irreversible and diffuse brain injury resulting in absence of clinical brain function
• cardiovascular activity may persist for up to 2 wk

Criteria of Diagnosis
• prerequisites: no CNS depressant drugs/neuromuscular blocking agents, no drug intoxication/poisoning, temperature >32°C, no electrolyte/acid-base/endocrine disturbance
• absent brainstem reflexes
  • absent pupillary light reflex
  • absent corneal reflexes
  • absent oculocephalic response
• absent caloric responses (e.g. no deviation of eyes to irrigation of each ear with 50 cc of ice water – allow 1 min after injection, 5 min between sides)
• absent pharyngeal and tracheal reflexes
• absent cough with tracheal suctioning
• absent respiratory drive at PaCO₂ >60 mmHg or >20 mmHg above baseline (apnea test)
• 2 evaluations separated by time, usually performed by two specialists (e.g. anesthetist, neurologist, neurosurgeon)
• confirmatory testing: flat EEG, absent perfusion assessed with cerebral angiogram

Coma

Definition
• an unrousable state in which patients show no meaningful response to environmental stimuli

Pathophysiology
• lesions affecting the cerebral cortex bilaterally, the reticular activating system (RAS) or their connecting fibers
• focal supratentorial lesions do not alter consciousness except by herniation (compression on the brainstem or on the contralateral hemisphere) or by precipitating seizures

Classification
• structural lesions (tumor, pus, blood, infarction, CSF): 1/3 of comas
  • supratentorial mass lesion: leads to herniation
  • infratentorial lesion: compression of or direct damage to the RAS or its projections
• metabolic disorders/diffuse hemispheric damage: 2/3 of comas
  • deficiency of essential substrates (e.g. oxygen, glucose, vitamin B₁₂)
  • exogenous toxins (e.g. drugs, heavy metals, solvents)
  • endogenous toxins/systemic metabolic diseases (e.g. uremia, hepatic encephalopathy, electrolyte imbalances, thyroid storm)
  • infections (meningitis, encephalitis)
  • trauma (concussion, diffuse shear axonal damage)

Investigations and Management
• ABCs
• labs: electrolytes, extended electrolytes, TSH, LFTs, Cr, BUN, toxin screen, glucose
• CT/MRI, LP, EEG

Persistent Vegetative State

Definition
• a condition of complete unawareness of the self and the environment accompanied by sleep-wake cycles with either complete or partial preservation of hypothalamic and brainstem autonomic function
• "awake but not aware"
• follows comatose state

Etiology/Prognosis
• most commonly caused by cardiac arrest or head injury
• due to irreversible loss of cerebral cortical function but intact brainstem function
• average life expectancy is 2-5 yr

Pediatric Neurosurgery

Spinal Dysrashism

SPINA BIFIDA OCCULTA

Definition
• congenital absence of a spinous process and a variable amount of lamina
• no visible exposure of meninges or neural tissue

Epidemiology
• 15-20% of the general population; most common at L5 or S1

Etiology
• failure of fusion of the posterior neural arch

Figure 27. Spina bifida occulta
Clinical Features
- no obvious clinical signs
- presence of lumbosacral cutaneous abnormalities (dimple, sinus, port-wine stain, or hair tuft) should increase suspicion of an underlying anomaly (lipoma, dermoid, diastematomyelia)

Investigations
- plain film: absence of the spinous process along with minor amounts of the neural arch
- U/S, MRI to exclude spinal anomalies

Treatment
- requires no treatment

MENINGOCELE (SPINA BIFIDA APERTA)

Definition
- herniation of meningeal tissue and CSF through a defect in the spine, without associated herniation of neural tissue

Etiology
- primary failure of neural tube closure

Clinical Features
- most common in lumbosacral area
- usually no disability, low incidence of associated anomalies, and hydrocephalus

Investigations
- plain films, CT, MRI, U/S, echo, GU investigations

Treatment
- surgical excision and tissue repair (excellent results)

MYELOMENINGOCELE (SPINA BIFIDA APERTA)

Definition
- herniation of meningeal and CNS tissue through a defect in the spine

Etiology
- same as meningocele

Clinical Features
- sensory and motor changes distal to anatomic level producing varying degrees of weakness
- urinary and fecal incontinence
- 65-85% of patients with myelomeningocele have hydrocephalus
- most have Type II Chiari malformation (see Chiari Malformations, NS36)

Investigations
- plain films, CT, MRI, U/S, echo, GU investigations

Treatment
- surgical closure to preserve neurologic status and prevent CNS infections
- closure in utero shown to decrease hydrocephalus and improve post natal motor scores

Prognosis
- operative mortality close to 0%, 95% 2 yr survival
- 80% have IQ >80 (but most are 80-95), 40-85% ambulatory, 3-10% have normal urinary continence
- early mortality usually due to Chiari malformation complications (respiratory arrest and aspiration), whereas late mortality is due to shunt malfunction

Intraventricular Hemorrhage
- see Pediatrics, P72
**Hydrocephalus in Pediatrics**

**Etiology**
- **congenital**
  - aqueductal anomalies, primary aqueductal stenosis in infancy
  - secondary gliosis due to intrauterine viral infections (mumps, varicella, TORCH)
  - Dandy-Walker malformation (2-4%)
  - Chiari malformation, especially Type II
  - myelomeningocele
- **acquired**
  - post meningitis
  - post hemorrhage (SAH, IVH)
  - masses (vascular malformation, neoplastic)

**Clinical Features**
- symptoms and signs of hydrocephalus are age related in pediatrics
- increased head circumference (HC), bulging anterior fontanelle, widened cranial sutures
- irritability, lethargy, poor feeding, and vomiting
- “cracked pot” sound on cranial percussion
- scalp vein dilation (increased collateral venous drainage)
- sunset sign – forced downward deviation of eyes
- episodic bradycardia and apnea

**Investigations**
- skull x-ray, U/S, CT, MRI, ICP monitoring

**Treatment**
- similar to adults (see Hydrocephalus, NS7)

---

**Dandy-Walker Malformation**

**Definition**
- atresia of foramina of Magendie and Luschka, resulting in
  - complete or incomplete agenesis of the cerebellar vermis with widely separated, hypoplastic cerebellar hemispheres
  - posterior fossa cyst, enlarged posterior fossa
  - dilatation of 4th ventricle (also 3rd and lateral ventricles)
- associated anomalies
  - hydrocephalus (90%)
  - agenesis of corpus callosum (17%)
  - occipital encephalocele (7%)

**Epidemiology**
- 2-4% of pediatric hydrocephalus

**Clinical Features**
- 20% are asymptomatic, seizures occur in 15%
- symptoms and signs of hydrocephalus combined with a prominent occiput in infancy
- ataxia, spasticity, poor fine motor control common in childhood

**Investigations**
- ultrasound, CT, MRI

**Treatment**
- asymptomatic patients require no treatment
- associated hydrocephalus requires surgical treatment
  - e.g. ventriculoperitoneal (VP) shunt, cystoperitoneal (CP) shunt, lumboperitoneal (LP) shunt, ventriculoatrial (VA) shunt, lumbar drain

**Prognosis**
- 75-100% survival, 50% have normal IQ

---

**Chiari Malformations**

**Definition**
- malformations at the medullary-spinal junction

**Etiology**
- unclear, likely maldevelopment/dysgenesis during fetal life
Categories

- Type I (cerebellar ectopia)
  - definition: cerebellar tonsils lie below the level of the foramen magnum
  - epidemiology: average age at presentation 15 yr
  - clinical features:
    - many are asymptomatic
    - scoliosis
    - brain compression
    - central cord syndrome (65%)
    - syringomyelia (50%)
    - foramen magnum compression syndrome (22%)
    - cerebellar syndrome (11%)
    - hydrocephalus (10%)

- Type II
  - definition: part of cerebellar vermis, medulla, and 4th ventricle extend through the foramen magnum often to midcervical region
  - almost always associated with a myelomingocele
  - epidemiology: present in infancy
  - clinical features: findings due to brainstem and lower cranial nerve dysfunction
  - syringomyelia, hydrocephalus in >80%

Investigations

- MRI

Treatment

- indications for surgical decompression
  - Type I: symptomatic patients (early surgery recommended; <2 yr post symptom onset) → suboccipital craniectomy, duraplasty
  - Type II: neurogenic dysphagia, stridor, apneic spells → cervical laminectomy, duraplasty

Craniosynostosis

Definition

- premature closure of the cranial suture(s)

Classification

- sagittal (most common): long narrow head with ridging sagittal suture (scaphocephaly)
- coronal: expansion in superior and lateral direction (brachiocephaly)
- metopic (trigonocephaly)
- lambdoid: least common

Epidemiology

- 0.6/1,000 live births, most cases are sporadic; familial incidence is 2% of sagittal and 8% of coronal synostosis

Clinical Features

- skull deformity, raised ICP ± hydrocephalus
- ophthalmologic problems due to increased ICP or bony abnormalities of the orbit
- must differentiate between positional plagiocephaly (secondary to back sleeping)

Investigations

- plain radiographs, CT scan

Treatment

- parental counseling about nature of deformity, associated neurological symptoms
- surgery for cosmetic purposes, except in cases of elevated ICP (≥2 sutures involved)

Pediatric Brain Tumors

- see Tumors, NS10

Epidemiology

- 20% of all pediatric cancers (second only to leukemia)
- 60% of pediatric brain tumors are infratentorial
- pediatric brain tumors arise from various cellular lineages
  - glia: low-grade astrocytoma (supra- or infratentorial), anaplastic astrocytoma, glioblastoma
  - primitive nerve cells: supratentorial PNET
  - non-neuronal cells: germ cell tumor, craniopharyngioma, dermoid, menigioma, neurinoma (schwanoma), pituitary adenoma, others
Clinical Features
• vomiting, seizure, macrocrania, hydrocephalus
• developmental delay, poor feeding, failure to thrive
• often initially escapes diagnosis due to expansile cranium and neural plasticity in children

Table 14. Overview of Childhood Primary Brain Tumors

<table>
<thead>
<tr>
<th>Tumor Type</th>
<th>Characteristics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pilocytic (low grade) Astrocytoma</td>
<td>Usually in posterior fossa, well circumscribed, good prognosis</td>
</tr>
<tr>
<td>Medulloblastoma</td>
<td>A primitive neuroectodermal tumor (PNET), compresses 4th ventricle, hydrocephalus, highly malignant</td>
</tr>
<tr>
<td>Ependymoma</td>
<td>In 4th ventricle, hydrocephalus, poor prognosis</td>
</tr>
<tr>
<td>Hemangioblastoma</td>
<td>Often cerebellar, associated with von Hippel-Lindau syndrome, retinal angiomas, can produce EPO to secondary polycythemia</td>
</tr>
<tr>
<td>Craniopharyngioma</td>
<td>Causes bitemporal hemianopsia (thus often confused with pituitary adenoma), most common supratentorial childhood tumor, benign</td>

</tr>
</tbody>
</table>

Surgical Management of Epilepsy

- see Neurology, N16 for the medical treatment of epilepsy

Indications
- medically refractory seizures, usually defined as seizures resistant to two first line anti-seizure medications used in succession
- identification of a distinct epileptogenic region through clinical history, EEG, MRI, and neuropsychological testing; other localizing investigations include magnetoencephalography, SPECT, and PET
- if a distinct epileptogenic region cannot be identified, the patient may be a candidate for a palliative procedure such as corpus callosotomy

Procedure
- adults: resection of the hippocampus and parahippocampal gyrus for mesial temporal lobe epilepsy arising from mesial temporal sclerosis
- children: resection of an epileptogenic space-occupying lesion
- hemispherectomy and corpus callosotomy are less common

Outcomes
- 41-79% of adult patients are seizure free for 5 yr after temporal lobe resection
- 58-78% of children are seizure free after surgery
- surgery is associated with improvements in preexisting psychiatric conditions such as depression and anxiety, as well as improvement in quality of life measures

Morbidity
- 0.4-4% of surgical patients will have partial hemianopia, aphasia, motor deficit, sensory deficit, or cranial nerve palsy following anteromedial temporal lobectomies
• most patients will have some decline in verbal memory following dominant temporal lobectomy and in visuospatial memory in non-dominant temporal resection
• the degree of memory decline stabilizes after 1-2 yr

Predictors
• positive predictive factors for seizure freedom following anteromedial temporal lobectomy
  ▪ hippocampal sclerosis (unilateral)
  ▪ focal localization of interictal epileptiform discharges
  ▪ absence of pre-operative generalized seizures
  ▪ tumoral cause
  ▪ complete resection of the lesion
  ▪ SES

Surgical Management for Trigeminal Neuralgia

• reserved for cases refractory to medical management; see Neurology, N8 for medical management

Surgical Options
• trigeminal nerve branch procedures
  ▪ local blocks (phenol, alcohol)
  ▪ neurectomy of the trigeminal branch
• nerve branches
  ▪ V1 block at the supraorbital, supratrochlear nerves
  ▪ V2 block at the foramen rotundum or infraorbital nerves
  ▪ V3 block at the foramen ovale
• percutaneous trigeminal rhizotomy
  ▪ glycerol injection
  ▪ mechanotrauma via catheter balloon
• radiofrequency thermocoagulation
• Gamma Knife® radiosurgery
• microvascular decompression
  ▪ posterior fossa craniotomy with microsurgical exploration of the root entry zone, displacement of the vessel impinging on the nerve with placement of non-absorbable 'Tellon' felt

Common Medications

<table>
<thead>

<th>Side Effects</th>
<th>Common Interactions</th>
<th>Contraindications</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>lorazepam (Ativan®)</td>
<td>4 mg IV over 2 min, q10-15min (do not exceed 8 mg/12h)</td>
<td>Status epilepticus</td>
<td>Drowsiness, sedation</td>
<td>Other CNS depressants, digoxin (increases digoxin levels)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>carbamazepine (Tegretol®)</td>
<td>Trigeminal neuralgia (tic douloureux): 100 mg PO bid, increase by 200 mg/d up to a maximum of 1,200 mg/d; Seizures: 200 mg PO bid, increase by 200 mg (irregular: q3d; outpatient: q7d) until therapeutic level achieved (usual optimum dosage: 800-1,200 mg/d; range: 600-2,000 mg/d)</td>
<td>Trigeminal neuralgia Seizures</td>
<td>Worsening of seizures, heart failure, arrhythmias, AV block, aplastic anemia, agranulocytosis, thrombocytopenia, hepatitis, erythema multiforme, Stevens-Johnson syndrome</td>
<td>Lithium (increases lithium toxicity), MAOI Other meds may increase carbamazepine levels or have decreased effects</td>
<td>Hypersensitivity to TCAs, previous bone marrow suppression, MAOI in past 14 d</td>
<td>Monitor CBC (potential hematological toxicity)</td>
</tr>
<tr>
<td>phenytoin (Dilantin®)</td>
<td>Seizures: Loading dose: 18 mg/kg slow IV or 300-600 mg PO divided bid/tid; Maintenance: 200-500 mg IV/d (max rate: &lt;40-50 mg/min or 300 mg PO q4h); average maintenance dose: 300 mg/d PO; Status epilepticus: 200 mg IV over 30 min (~20 mg/kg: if not taking regularly), or 500 mg IV over 10 min (if already on phenytoin)</td>
<td>Seizures</td>
<td>Thrombocytopenia, leukopenia, agranulocytosis, pancytopenia, toxic hepatitis, Stevens-Johnson syndrome, toxic epidermal necrolysis</td>
<td>Other meds may increase phenytoin levels and toxicity or have decreased effects</td>
<td>Bradyarrhythmias, heart block</td>
<td>Important to give over time to prevent causing a cardiac arrest</td>
</tr>
</tbody>
</table>
### Table 18. Common Medications (continued)

<table>
<thead>
<tr>
<th>Drug Name</th>
<th>Dosing Schedule</th>
<th>Indications</th>
<th>Side Effects</th>
<th>Common Interactions</th>
<th>Contraindications</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Dexamethasone</strong> (Decadron&lt;sup&gt;®&lt;/sup&gt;)</td>
<td>Loading dose: 10-20 mg IV/Maintenance: 4-6 mg IV/d divided qid (may be PO)</td>
<td>Cerebral edema (e.g. secondary to tumor, head injury, pseudotumor cerebri) Pre-operative preparation for patients with increased ICP secondary to brain neoplasms</td>
<td>Pseudotumor cerebri, seizures, heart failure, arhythmias, thromboembolism, pancreatitis, acute adrenal insufficiency; avoid abrupt withdrawal</td>
<td>Aminoglutethimide, antibiotics, ASA, NSAIDs, barbituates, phenytoin, rifampin, cardiac glycosides, cyclosporine, ephedrine, oral anticoagulants, potassium-depleting drugs, salicylates, skin-testing antigens, toxoids, vaccines</td>
<td>Systemic fungal infections, immunosuppressive dose with live virus vaccines</td>
<td>No longer used in acute spinal cord injury</td>
</tr>
<tr>
<td><strong>Mannitol</strong></td>
<td>1-1.5 g/kg IV rapid infusion (350 mL of 20% solution) followed by 0.25 g/kg IV q6h</td>
<td>Raised ICP</td>
<td>Seizures, heart failure</td>
<td>Lithium (increases excretion of lithium)</td>
<td>Anuria, severe pulmonary congestion, frank pulmonary edema, severe dehydration, metabolic edema, progressive renal disease or dysfunction, active intracranial bleeding except during craniotomy</td>
<td>Effect occurs in 1-5 min, maximal at 20-60 min</td>
</tr>
<tr>
<td><strong>Nimodipine</strong> (Nimotop&lt;sup&gt;®&lt;/sup&gt;)</td>
<td>60 mg PO/NG q4h x 21 d started within 96 h of SAH</td>
<td>Vasospasm in SAH</td>
<td>Decreased blood pressure, tachycardia, dyspnea</td>
<td>Antihypertensives (may increase hypotensive effects), CCB (may increase effects), cimetidine (increases nimodipine bioavailability)</td>
<td>None known</td>
<td>Causes vasodilation Only calcium channel blocker that crosses blood brain barrier Use half the normal dose for liver failure; monitor BP always</td>
</tr>
</tbody>
</table>

Pregnancy

Diagnosis of Pregnancy

History
- obstetrical and gynecological history
- obtain the year, location, mode of delivery, duration of labor, sex, gestational age, birth weight, and complications of every pregnancy; organize into GTPAL format
  - Gravidity (G)
    - G: total number of pregnancies of any gestation
    - includes current pregnancy, abortions, ectopic pregnancies, and hydatidiform moles (multiple gestation = one pregnancy)
  - Parity (TPAL)
    - T: number of term infants delivered (>37 wk)
    - P: number of premature infants delivered (20-36+6 wk)
    - A: number of abortions (loss of intrauterine pregnancy prior to viability of fetus <20 wk and/or <500 g fetal weight)
    - L: number of living children
- symptoms: amenorrhea, N/V, breast tenderness, urinary frequency, fatigue

Physical Signs
- Goodell’s sign: softening of the cervix (4-6 wk)
- Chadwick’s sign: bluish discoloration of the cervix and vagina due to pelvic vasculature engorgement (6 wk)
- Hegar’s sign: softening of the cervical isthmus (6-8 wk)
- uterine enlargement
- breast engorgement

Acronyms

AC abdominal circumference
ACOG American Congress of Obstetricians and Gynecologists
AFI amniotic fluid index
AFP acute fatty liver of pregnancy
AFV amniotic fluid volume
AP anteroposterior
APS antiphospholipid antibody syndrome
BPP biophysical profile
C/S Cesarean section
CPD cephalopelvic disproportion
CTG cardiotocography
CVS chorionic villus sampling
DIC disseminated intravascular coagulation
DVT deep vein thrombosis
ECV external cephalic version
EDC estimated date of confinement
EFM electronic fetal monitoring
EFW estimated fetal weight
FDP fibrin degradation products
FHR fetal heart rate

GDM gestational diabetes mellitus
GTN gestational trophoblastic neoplasia
HC head circumference
HELLP hemolysis, elevated liver enzymes, low platelets
IGF infant growth factors
IMM intramyometrial
IOL induction of labor
IPS integrated prenatal screen
IUD intrauterine fetal death
IUGR intrauterine growth restriction
IHH intraventricular hemorrhage
LDOP left lateral decubitus position
LMP last menstrual period
MAMA maternal serum α-fetoprotein
MSAFP maternal serum screen
MTX methotrexate
NIPF non-invasive prenatal testing
NST non-stress test
NTDs neural tube defects
NTUS nuchal translucency ultrasound
OA occiput anterior
OGTT oral glucose tolerance test
ONT open neural tube defect
OP occiput posterior
OT occiput transverse
PAPP-A pregnancy-associated plasma protein A
PG plasma glucose
PPD postpartum depression
PPH postpartum hemorrhage
PPROM preterm premature rupture of membranes
PROM premature rupture of membranes
PTL preterm labor
RDS respiratory distress syndrome
ROM rupture of membranes
SA spontaneous abortion
SFH symphysis fundal height
SVD spontaneous vaginal delivery
TENS transcutaneous electrical nerve stimulation
TPN total parenteral nutrition
UTI urinary tract infection
VBAC vaginal birth after Cesarean

Figure 1. Placental blood flow

Placenta
- site of fetal nutritive, respiratory, and excretory function
- discoid mass composed of fetal (chorion frondosum) and maternal (decidua basalis) tissues divided by fissures into cotyledons (lobules) on the uterine side
- produces hormones such as progesterone, placental lactogen, estrogen, relaxin, β-hCG, and IGFs
- poor implantation can lead to spontaneous abortion
- abnormal location, implantation, or detachment can lead to antepartum hemorrhage (see Antepartum Hemorrhage, OB24)
Investigations

- β-hCG: peptide hormone composed of α and β subunits produced by placental trophoblastic cells – maintains the corpus luteum during pregnancy
  - positive in serum 9 d post-conception, positive in urine 28 d after first day of LMP
  - plasma levels double every 1-2 d, peak at 8-10 wk, then fall to a plateau until delivery
  - levels less than expected by dates suggest: ectopic pregnancy, abortion, or inaccurate dates
  - levels higher than expected suggest: multiple gestation, molar pregnancy, Trisomy 21, or inaccurate dates
- U/S
  - transvaginal
    - 5 wk: gestational sac visible
    - 6 wk: fetal pole seen
    - 7-8 wk: fetal heart tones visible
  - transabdominal
    - 6-8 wk: intrauterine pregnancy visible (β-hCG ≥6,500 mIU/mL)

Maternal Physiology

Table 1. Physiologic Changes During Pregnancy

<table>
<thead>
<tr>
<th>Skin</th>
<th>Increased pigmentation of perineum and areola, chloasma (pigmentation changes under eyes and on bridge of nose), linea nigra (midline abdominal pigmentation) Other: spider angiomas, palmar erythema due to increased estrogen, striae gravidarum due to connective tissue changes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cardiovascular</td>
<td>Hyperdynamic circulation Increased CO, HR, and blood volume Decreased BP due to decreased PVR Enlarging uterus compresses IVC and pelvic veins Decreased venous return leads to risk of hypotension Increased venous pressure leads to risk of varicose veins, hemorrhoids, leg edema</td>
</tr>
<tr>
<td>Hematologic</td>
<td>Hemodilution causes physiologic anemia and apparent decrease in hemoglobin and hematocrit Increased leukocyte count but impaired function leads to improvement in autoimmune diseases Gestational thrombocytopenia: mild (platelets &gt;70,000/µL) and asymptomatic, normalizes within 2-12 wk following delivery Hypercoagulable state: increased risk of DVT and PE but also decreased bleeding at delivery</td>
</tr>
<tr>
<td>Respiratory</td>
<td>Increased incidence of nasal congestion and epistaxis Increased O₂ consumption to meet increased metabolic requirements Elevated diaphragm (i.e. patient appears more “barrel-chested”) Increased minute ventilation leads to decreased CO₂ resulting in mild respiratory alkalosis that helps CO₂ diffuse across the placenta from fetal to maternal circulation No change in VC and FEV₁ Decreased TLC, FRC, and RV</td>
</tr>
<tr>
<td>Gastrointestinal</td>
<td>GERD due to increased intra-abdominal pressure and progesterone (causing decreased sphincter tone and delayed gastric emptying) Increased gallstones due to progesterone causing increased gallbladder stasis Constipation and hemorrhoids due to progesterone causing decreased GI motility</td>
</tr>
<tr>
<td>Genitourinary</td>
<td>Increased urinary frequency due to increased total urinary output Increased incidence of UTI and pyelonephritis due to urinary stasis (see Urinary Tract Infection, OB19) Glycosuria that can be physiologic especially in the 3rd trimester Ureters and renal pelvis dilation (R&gt;L) due to progesterone-induced smooth muscle relaxation and uterine enlargement Increased CO₂ and thus increased GFR leads to decreased creatinine (normal in pregnancy 0.4-0.5 mg/dL), uric acid, and BUN</td>
</tr>
<tr>
<td>Neurologic</td>
<td>Increased incidence of carpal tunnel syndrome and Bell’s palsy</td>
</tr>
<tr>
<td>Endocrine</td>
<td>Thyroid: moderate enlargement and increased basal metabolic rate Increased total thyroxine and thyroxine binding globulin (TBG) Free thyroxine index and TSH levels are normal Adrenal: maternal cortisol rises throughout pregnancy (total and free) Calcium: decreased total maternal Ca²⁺ due to decreased albumin Free ionized Ca²⁺ (i.e. active) proportion remains the same due to parathyroid hormone (PTH), results in increased bone resorption and gut absorption, increased bone turnover (but no loss of bone density due to estrogen inhibition)</td>
</tr>
</tbody>
</table>
Prenatal Care

- provided by obstetrician, family doctor, midwife, or multidisciplinary team (based on patient preference and risk factors)
- Antenatal Records (province specific)

Preconception Counseling

- 3-8 wk GA is a critical period of organogenesis, so early preparation is vital

- past medical history: optimize medical illnesses and necessary medications prior to pregnancy (see Medical Conditions in Pregnancy, OB13, and Medications in Pregnancy, OB10)

- supplementation
  - folic acid: encourage diet rich in folic acid and supplement 8-12 wk preconception until end of T1 to prevent NTDs
    - 0.4-1 mg daily in all women; 5 mg if previous NTD, antiepileptic medications, DM, or BMI >35 kg/m²
  - iron supplementation, prenatal vitamins

- risk modification
  - lifestyle: balanced nutrition and physical fitness
  - medications: patients with chronic diseases should discuss whether their medications may be teratogenic prior to conception so they may be adjusted; it is not advised to stop medications abruptly when becoming pregnant
  - infection screening: rubella, HBsAg, VDRL, Pap smear, gonorrhea/chlamydia, HIV
  - genetic testing as appropriate for high risk groups (see Prenatal Screening, Table 2); consider genetics referral in known carriers, recurrent pregnancy loss/stillbirth, family members with developmental delay or birth anomalies
  - social: alcohol, smoking, drug use, domestic violence (see Family Medicine, FM12, FM10, FM28)

Initial Prenatal Visit

- usually within 12 wk of the first day of LMP or earlier if <20 or >35 yr old or other risk factors are present
- Antenatal Records are filled out on the first prenatal visit

History

- gestational age by dates from the first day of the LMP
- if LMP unreliable, get a dating ultrasound which could coincide with nuchal translucency at ~12 wks
- dates should change if T1 U/S is greater than 5 days in difference from LMP due date
  - 1st day of LMP + 7 d – 3 mo
  - e.g. LMP = 1 Apr 2013, EDC = 8 Jan 2014 (modify if cycle >28 d by adding number of d >28)
- history of present pregnancy (e.g. bleeding, N/V)
- history of all previous pregnancies
- past medical history, past gynecological history
- prescription and non-prescription medications
- family history: genetic disease, birth defects, multiple gestation
- social history: smoking, alcohol, drug use, domestic violence (see Family Medicine, FM10, FM12, FM28), consanguinity

Physical Exam

- complete exam to obtain baseline patient information
- BP and weight important for interpreting subsequent changes
- pelvic exam

Investigations

- blood work
  - CBC, blood group and type, Rh antibodies, infection screening as per preconception counseling
  - urine R&O, C&S
  - screen for bacteriuria and proteinuria
- pelvic exam
  - Pap smear (only if required according to patient history and state screening guidelines), cervical culture for N. gonorrhoeae (GC) and C. trachomatis, vaginal swab for bacterial vaginosis (BV)
Subsequent Prenatal Visits

Timing
- for uncomplicated pregnancies, q4-6wk until 28 wk, q2-3wk from 28 to 36 wk, and weekly from 36 wk until delivery

Assess at Every Visit
- record estimated GA
- history of present pregnancy: fetal movements, uterine bleeding, leaking, cramping
- physical exam: BP, weight gain, thyroid exam, SFH, Leopold’s maneuvers (T3) for lie, position, and presentation of fetus
- investigations: urinalysis for glucosuria, proteinuria; fetal heart rate starting at 12 wk using Doppler U/S

Leopold’s Maneuvers
- performed after 30-32 wk gestation
- first maneuver: to determine which fetal part is lying furthest away from the pelvic inlet
- second maneuver: to determine the location of the fetal back
- third maneuver: to determine which fetal part is lying above the pelvic inlet
- fourth maneuver: to locate the fetal brow

Screening Tests
- testing should only occur following counseling and with the informed consent from the patient

Table 2. High-Risk Population Screening Tests

<table>
<thead>
<tr>
<th>Disease (Inheritance)</th>
<th>Population(s) at Risk</th>
<th>Screening Test(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Thalassemia (AR)</td>
<td>Mediterranean, South East Asian, Western Pacific, African, Middle Eastern, Caribbean, South American</td>
<td>CBC (MCV and MCH), Hb electrophoresis, or HPLC</td>
</tr>
<tr>
<td>Sickle Cell (AR)</td>
<td>African, Caribbean, Mediterranean, Middle Eastern, Indian, South American</td>
<td>CBC (MCV and MCH), Hb electrophoresis, or HPLC</td>
</tr>
<tr>
<td>Cystic Fibrosis (CF) (AR)</td>
<td>Mediterranean, Finnish, Caucasian, or FHx</td>
<td>CFTR gene DNA analysis</td>
</tr>
<tr>
<td>Tay Sachs Disease (CF) (AR)</td>
<td>Ashkenazi Jewish*, French Canadians, Cajun</td>
<td>Enzyme assay HEXA, or DNA analysis</td>
</tr>
<tr>
<td>Fragile X Syndrome (X-linked)</td>
<td>Family history – confirmed or suspected</td>
<td>DNA analysis: FMR-1 gene</td>
</tr>
</tbody>
</table>

AR = autosomal recessive; HEXA = hexosaminidase A; HPLC = high performance liquid chromatography
*If both partners are Ashkenazi Jewish, test for Canavan disease and Familial Dysautonomia (FD); if family history of a specific condition, look for carrier status: e.g. Gaucher, CF, Bloom syndrome, Niemann-Pick disease, etc. In all cases, if both partners positive, refer for genetic counseling.
Table 3. Gestation-Dependent Screening Investigations

<table>
<thead>
<tr>
<th>Gestational Age (wk)</th>
<th>Investigations Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>8-12</td>
<td>Dating U/S, possible Pap smear, chlamydia/gonorrhea cultures, urine C/S, HIV, VDRL, HepB5Ag, Rubella IgG, Parvovirus IgM or IgG if high risk (small child at home or daycare worker/primary teacher), Varicella IgG if no history of disease/immunization, CBC, blood group and screen</td>
</tr>
<tr>
<td>10-12</td>

</tr>
<tr>
<td>35-37</td>
<td>GBS screen</td>
</tr>
<tr>
<td>6 wk postpartum</td>
<td>Discuss contraception, menses, breastfeeding, depression, mental health, support Physical exam: breast exam, pelvic exam including Pap smear</td>
</tr>
</tbody>
</table>

Maternal serum screen is also referred to as Triple Screen; if Inhibin A is also tested, it is referred to as Quadruple Screen
Ideally testing for MSS and IPS Part 2 occur between 15-18 wk to give women more time to make decisions and move ahead with diagnostic testing should the resulting screen be positive

Ultrasound Screening
- dating ultrasound best done between 8-12 wk GA (most accurate form of pregnancy dating)
  - measurement of crown-rump length (margin of error ± 5 d)
  - change EDC to U/S date if >5 d discrepancy from EDC based on LMP
- NTUS at 11-14 wk GA
  - measures the amount of fluid behind the neck of the fetus
  - early screen for Trisomy 21 (may also detect cardiac and other aneuploidies like Turner’s syndrome)
  - NT measurement is necessary for the FTS and IPS Part 1
- fetal growth and anatomy ultrasound routinely done at 18-20 wk GA (margin of error ± 10 d)
- earlier or subsequent ultrasounds performed when medically indicated

Table 4. Comparison of FTS, MSS, and IPS

<table>
<thead>
<tr>
<th>FTS</th>
<th>MSS</th>
<th>IPS</th>
</tr>
</thead>
<tbody>
<tr>
<td>11-14 wk</td>
<td>Risk estimate for 1. Down syndrome (Trisomy 21): increased NT, increased β-hCG, decreased PAPP-A</td>
<td></td>
</tr>
<tr>
<td>15-20 wk</td>
<td>Risk estimate for 1. oNTD: increased MSAFP (sensitivity 80-90%) 2. Trisomy 21: decreased MSAFP; increased β-hCG, decreased µE3 (sensitivity 65%) 3. Trisomy 18: decreased MSAFP; decreased β-hCG, decreased µE3 (sensitivity 80%) Only offered alone if patient missed the time window for IPS or FTS 8% baseline false positive rate for Trisomy 21, lower for oNTD and Trisomy 18 Patients with positive screen should be offered U/S, amniocentesis, or NIPT</td>
<td></td>
</tr>
<tr>
<td>Nuchal translucency on 12 wk U/S FTS at 11-14 wk MSS + Inhibin A at 15-20 wk Risk estimate for oNTD, Trisomy 21, Trisomy 18 Sensitivity ~85-90% 2% false positive rate Patients with positive screen should be offered U/S and/or amniocentesis or NIPT</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Note: In twins, FTS, MSS, and IPS are not applicable; screen with NT for chromosomal abnormalities and MSAFP for oNTDs
Diagnostic Tests

Indications
- maternal age >35 yr (increased risk of chromosomal anomalies)
- risk factors in current pregnancy
  - abnormal U/S
  - abnormal prenatal screen (IPS, FTS, or MSS)
- past history/family history of:
  - previous pregnancy with chromosomal anomaly or genetic disease
  - either parent a known carrier of a genetic disorder or balanced translocation
  - family history of chromosomal anomaly, genetic disorder, birth defect, or undiagnosed mental retardation
  - consanguinity
  - three or more spontaneous abortions

AMNIOCENTESIS
- U/S-guided transabdominal extraction of amniotic fluid

Indications
- identification of genetic anomalies (15-16 wk gestation) as per indications above
- assessment of fetal lung maturity (T3) via the L/S ratio (lecithin:sphingomyelin)
  - if >2:1, RDS is less likely to occur

Advantages
- also screens for oNTD (acetylcholinesterase and amniotic AFP) – 96% accurate
- in women >35 yr, the risk of chromosomal anomaly (1/180) is greater than the risk of miscarriage from the procedure
- more accurate genetic testing than CVS

Disadvantages
- 1/400 – 1/500 risk of spontaneous abortion
- results take 14-28 d; FISH can be done on chromosomes X, Y, 21, 13, 18 to give preliminary results in 48 h

CHORIONIC VILLUS SAMPLING
- biopsy of fetal-derived chorion using a transabdominal needle or transcervical catheter at 10-12 wk

Advantages
- enables pregnancy to be terminated earlier than with amniocentesis
- rapid karyotyping and biochemical assay within 48 h, including FISH analysis
- high sensitivity and specificity

Disadvantages
- 1-2% risk of spontaneous abortion
- does not screen for oNTD
- 1-2% incidence of genetic mosaicism “false negative” results

ISOIMMUNIZATION SCREENING

Definition
- isoimmunization: antibodies (Ab) produced against a specific RBC antigen (Ag) as a result of antigenic stimulation with RBC of another individual

Etiology
- maternal-fetal circulation normally separated by placental barrier, but sensitization can occur and can affect the current pregnancy, or more commonly, future pregnancies
- in pregnancy, anti-Rh Ab produced by a sensitized Rh-negative mother can lead to fetal hemolytic anemia
- overall risk of isoimmunization of an Rh-negative mother with an Rh-positive ABO-compatible infant is 16%
- sensitization routes
  - incompatible blood transfusions
  - previous fetal-maternal transplacental hemorrhage (e.g. ectopic pregnancy, abruption)
  - invasive procedures in pregnancy (e.g. prenatal diagnosis, cerclage, D&C)
  - any type of abortion
  - labor and delivery

NON-INVASIVE PRENATAL TESTING (NIPT)
- New non-invasive screening for Down syndrome in spontaneous singleton pregnancies
- Analyzes maternal blood for circulating cell free fetal DNA (ccffDNA) at 10 wk GA
- High sensitivity (98-99%), FP<2%
- Disadvantages: less sensitive for Trisomy 18 and 13, does not screen for oNTD, not widely available

DDx of Increased MSAFP
- Incorrect GA
- >1 fetus (e.g. twins)
- Fetal demise
- oNTD
- Abdominal wall defects (e.g. omphalocele)

DDx of Decreased MSAFP
- Incorrect GA
- Gestational trophoblastic neoplasia
- Missed abortion
- Chromosomal anomalies
- Maternal diabetes

ISOFETAL MSAFP
- 10 mL of maternal serum collected for analysis of fetal alpha-fetoprotein (AFP) at 15-17 wk

Advantages
- high accuracy
- non-invasive

Disadvantages
- requires maternal serum
- gestational age dependent

Compared to CVS, amniocentesis has a higher accuracy of prenatal cytogenetic diagnosis (99.8% vs. 97.5%) and lower risk of spontaneous abortion (0.5% vs. 1-2%)

Risk Factors for Neural Tube Defects

GRIMM
- Genetics: family history of NTD (risk of having second child with NTD is increased to 2-5%), consanguinity, chromosomal (characteristic of Trisomy 13, 18, and 21)
- Race: European Caucasians > African Americans, 3-fold higher in Hispanics
- Insufficient vitamins: zinc and folate
- Maternal chronic disease (e.g. DM)
- Maternal use of antiepileptic drugs
- General population risk for NTD is 0.1%
Investigations

- routine screening with indirect Coombs test at first visit for blood group, Rh status, and antibodies
- Kleihauer-Betke test used to determine extent of fetomaternal hemorrhage by estimating volume of fetal blood volume that entered maternal circulation
- detailed U/S for hydrops fetalis

Prophylaxis

- exogenous Rh IgG (Rhogam® or WinRho®) binds to Rh antigens of fetal cells and prevents them from contacting maternal immune system
- Rhogam® (300 µg) given to all Rh negative and antibody screen negative women in the following scenarios
  - routinely at 28 wk GA (provides protection for ~12 wk)
  - within 72 h of the birth of an Rh positive fetus
  - with a positive Kleihauer-Betke test
  - with any invasive procedure in pregnancy (CVS, amniocentesis)
  - in ectopic pregnancy
  - with miscarriage or therapeutic abortion (only 50 µg required)
- if Rh negative and Ab screen positive, follow mother with serial monthly Ab titres throughout pregnancy ± serial amniocentesis as needed (Rhogam® has no benefit)

Investigations

- MCA dopplers are done to assess degree of fetal anemia or if not available bilirubin is measured by serial amniocentesis to assess the severity of hemolysis
- cordocentesis for fetal Hb should be used cautiously (not first line)

Treatment

- falling biliary pigment warrants no intervention (usually indicative of either unaffected or mildly affected fetus)
- intrauterine transfusion of O-negative pRBCs may be required for severely affected fetus or early delivery of the fetus for exchange transfusion

Complications

- anti-Rh IgG can cross the placenta and cause fetal RBC hemolysis resulting in fetal anemia, CHF, edema, ascites
- severe cases can lead to fetal hydrops (edema in at least two fetal compartments due to fetal heart failure secondary to anemia) or erythroblastosis fetalis (moderate to severe immune-mediated hemolytic anemia)

GROUP B STREPTOCOCCUS SCREEN

Epidemiology

- 15-40% vaginal carrier rate

Risk Factors (for neonatal disease)

- GBS bacteriuria during current pregnancy even if treated
- previous infant with invasive GBS infection
- preterm labor <37 wk
- ruptured membranes >18 h before delivery
- intrapartum maternal temperature 100.4°F
- positive GBS screen during current pregnancy

Clinical Features

- not harmful to mother
- risk of vertical transmission (neonatal sepsis, meningitis or pneumonia, and death)

Investigations

- offer screening to all women at 35-37 wk with vaginal and anorectal swabs for C&S

Treatment

- treatment of maternal GBS at delivery decreases neonatal morbidity and mortality
- indications for antibiotic prophylaxis: positive GBS screen or GBS status unknown and one of the risk factors
- antibiotics for GBS prophylaxis
  - penicillin G 5 million units IV then 2.5 million units IV q4h until delivery
  - penicillin allergic but not at risk for anaphylaxis: cefazolin 2 g IV then 1 g q8h
  - penicillin allergic and at risk for anaphylaxis: vancomycin 1 g IV q12h until delivery
- if fever, broad spectrum antibiotic coverage is advised
Counseling of the Pregnant Woman

Nutrition

- 3-4 servings of milk products daily (greater if multiple gestation)
- a daily caloric increase of ~100 cal/d in the 1st trimester, ~300 cal/d in the second and third trimesters and ~450 cal/d during lactation
- daily multivitamin should be continued in the 2nd trimester for women who do not consume an adequate diet; otherwise routine vitamin supplementation is not necessary (avoid excess vitamin A)
- nutrients important during pregnancy
  - folate: 0.4 mg/d for first 12 wk (5 mg/d if high risk)
  - supports maternal increase in blood volume, growth of maternal and fetal tissue, decreases incidence of neural tube defects
  - foods rich in folic acid include: spinach, lentils, chick peas, asparagus, broccoli, peas, Brussels sprouts, corn, and oranges
  - calcium: 1,200-1,500 mg/d
  - maintains integrity of maternal bones, skeletal development of fetus, breast milk production
  - vitamin D: 1,000 IU
  - promotes calcium absorption
  - iron: 0.8 mg/d in T1, 4-5 mg/d in T2, and >6 mg/d in T3
  - supports maternal increase in blood cell mass, supports fetal and placental tissue
  - required amounts exceed normal body stores and typical intake, and therefore need supplemental iron
  - iron is the only known nutrient for which requirements during pregnancy cannot be met by diet alone (see Iron Deficiency Anemia, OB13)
  - essential fatty acids – supports fetal neural and visual development
  - contained in vegetable oils, margarines, peanuts, fatty fish

Caffeine

- diuretic and stimulant that readily crosses placenta
- less than 300 mg/d is not thought to contribute to miscarriage or preterm birth (ACOG)
- relationship between caffeine and IUGR is unknown (ACOG)
- 1-2 cups/d is accepted as safe during pregnancy

Herbal Teas and Preparations

- not enough scientific information about safety of various herbs and herbal products to recommend their use during pregnancy
- some herbal teas can have toxic or pharmacological effects on the mother or fetus
- chamomiles have been reported to exhibit adverse effects on the uterus

Food Borne Illnesses

- microbiological contamination of food may occur through cross-contamination and/or improper food handling
  - listeriosis (Listeria monocytogenes) and toxoplasmosis (Toxoplasma gondii) are of concern during pregnancy
  - avoid consumption of raw meats, fish, poultry, raw eggs, and unpasteurized dairy products
  - avoid unpasturized soft cheeses, deli meats, smoked salmon, and pates as they may be sources of Listeria
  - chemical contamination of food
  - current guideline for mercury of 0.5 ppm in fish is not considered harmful for the general population, including pregnant women
  - consumption of top predator fish such as shark, swordfish, king mackeral, tilefish, and fresh/frozen tuna (not canned tuna) should be limited to one meal per month

Lifestyle

- exercise under physician guidance
- absolute contraindications
  - ruptured membranes, preterm labor, hypertensive disorders of pregnancy, incompetent cervix, IUGR, multiple gestations (>3), placenta previa after 28th wk, persistent 2nd or 3rd trimester bleeding, uncontrolled type 1 DM, uncontrolled thyroid disease, or other serious cardiovascular, respiratory, or systemic disorder
• relative contraindications
  ▪ previous preterm birth, mild/moderate cardiovascular or respiratory disorder, anemia (Hb ≤10 g/dL), malnutrition or eating disorder, twin pregnancy after 28th wk, other significant medical conditions
• weight gain: optimal gain depends on pre-pregnancy BMI (varies from 6.8-18.2 kg)
• work: strenuous work, extended hours and shift work during pregnancy may be associated with greater risk of low birth weight, prematurity, and spontaneous abortion
• travel: not harmful, but stress related to travel may be associated with preterm labor
  ▪ air travel is acceptable in second trimester; airline cutoff for travel is 36-38 wk gestation depending on the airline to avoid giving birth on the plane
• sexual intercourse: may continue, except in patients at risk for: abortion, preterm labor, or placenta previa; breast stimulation may induce uterine activity and is discouraged in high-risk patients near term
• smoking: assist/encourage to reduce or quit smoking
  ▪ increased risk of: decreased birth weight, placenta previa/abruption, spontaneous abortion, preterm labor, stillbirth
• alcohol: no amount of alcohol is safe in pregnancy; encourage abstinence from alcohol during pregnancy; alcohol increases incidence of abortion, stillbirth, and congenital anomalies
  ▪ fetal alcohol syndrome (see Pediatrics, P24)
• cocaine: microcephaly, growth retardation, prematurity, abruptio placentae

Medications

• most drugs cross the placenta to some extent
• very few drugs are teratogenic, but very few drugs have proven safety in pregnancy
• use any drug with caution and only if necessary
• analgesics: acetaminophen preferable to ASA or ibuprofen

Table 5. Documented Adverse Effects, Contraindicated

</tbody>
</table>

Immunizations

Intrapartum
• administration is dependent on the risk of infection vs. risk of immunization complications
• safe: tetanus toxoid, diphtheria, influenza, hepatitis B, pertussis
• avoid live vaccines (risk of placental and fetal infection): polio, measles/mumps/rubella, varicella
• contraindicated: rubella, oral typhoid

Postpartum
• rubella vaccine for all non-immune mothers
• hepatitis B vaccine should be given to infant within 12 h of birth if maternal status unknown or positive – follow-up doses at 1 and 6 mo
• human papillomavirus (HPV) vaccine – if meets criteria
• safe: tetanus toxoid, diphtheria, influenza, hepatitis B, pertussis

General Rule: 1-3.5 kg/wk during T1, then 0.45 kg/wk until delivery
Radiation

- Ionizing radiation exposure is considered teratogenic at high doses
- If indicated for maternal health, should be done
- Imaging not involving direct abdominal/pelvic high dosage is not associated with adverse effects
- Higher dosage to fetus: plain x-ray of lumbar spine/abdomen/pelvis, barium enema, CT abdomen, pelvis, lumbar spine
- Most investigations involve minimal radiation exposure
- Radioactive isotopes of iodine are contraindicated
- No known adverse effects from U/S or MRI (long-term effects of gadolinium unknown, avoid if possible)

Termination of Pregnancy

- See Gynecology, GY20

**Definition**

- Active termination of a pregnancy before fetal viability (usually <500 g or <20 wk GA)

**Indications**

- Inability to carry a pregnancy to term due to medical or social reasons (including patient preference)

**Management**

- Medical
  - <9 wk: methotrexate + misoprostol
  - >12 wk: prostaglandins (intra- or extra-amniotically or IM) or misoprostol
- Surgical
  - <12 wk: dilatation + vacuum aspiration ± curettage
  - >12 wk: dilatation and evacuation, early induction of labor
  - Common complications: pain or discomfort
  - Less common complications: hemorrhage, perforation of uterus, laceration of cervix, risk of infertility, infection/endometritis, Asherman’s syndrome (adhesions within the endometrial cavity causing amenorrhea/infertility), retained products of conception
- Counseling
  - Supportive and counseling services
  - Future contraception and family planning services
  - Ensure follow-up

Radiation in Pregnancy

- Necessary amount to cause miscarriage: >5 rads
- Necessary amount to cause malformations: >20-30 rads

CMA Policy (1988)

"Induced abortion should be uniformly available to all women in Canada" and "there should be no delay in the provision of abortion services"

Terminations are generally done until the stage of viability (~23.5 wk), although this varies depending on the provider

For prevention of pregnancy after rape, ensure appropriate access to emergency contraception (see Gynecology, GY20)
Prenatal Fetal Monitoring

Fetal Movements

- Patients will generally first notice fetal movement ("quickening") at 18-20 wk in primigravidas; can occur 1-2 wk earlier in multigravidas; can occur 1-2 wk later if placenta is implanted on the anterior wall of uterus.
- If the patient is concerned about decreased fetal movement, she is counseled to choose a time when the fetus is normally active to count movements (usually recommended after 26 wk).
- All high risk women should be told to do FM counts.
- If there is a subjective decrease in fetal movement, try drinking juice, eating, changing position, or moving to a quiet room and count for 2 h. ≥6 movements in 2 h expected.
- If there are <6 movement counts in 2 h, patient should present to labor and delivery triage.

NON-STRESS TEST

Definition

- FHR tracing ≥20 min using an external Doppler to assess FHR and its relationship to fetal movement (see Fetal Monitoring in Labor, OB33).

Indication

- Any suggestion of uteroplacental insufficiency or suspected compromise in fetal well-being.

Table 8. Classification of Antepartum Non-Stress Test

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Normal NST (Previously &quot;Reactive&quot;)</th>

<td>&gt;2 accelerations with acme of &gt;10 bpm, lasting 10 s in &lt;40 min</td>
<td>&lt;2 accelerations with acme of &gt;10 bpm, lasting 10 s in 40-80 min</td>
<td>&lt;2 accelerations with acme of &gt;10 bpm, lasting 10 s in &gt;80 min</td>
</tr>
<tr>
<td>Action</td>
<td>FURTHER ASSESSMENT OPTIONAL, based on total clinical picture</td>
<td>FURTHER ASSESSMENT REQUIRED</td>
<td>URGENT ACTION REQUIRED An overall assessment of the situation and further investigation with U/S or BPP is required; some situations will require delivery</td>
</tr>
</tbody>
</table>

Operating Characteristics

- False positive rate depends on duration; false negative rate = 0.2-0.3%.

Interpretation

- Normal: at least 2 accelerations of FHR ≥15 bpm from the baseline lasting >15 s in 20 min.
- Abnormal: <2 accelerations of FHR in 40 min.
- If no observed accelerations or fetal movement in the first 20 min, stimulate fetus (fundal pressure, acoustic/vibratory stimulation) and continue monitoring for 30 min.
- If NST abnormal, then perform BPP.

BIOPHYSICAL PROFILE

Definition

- U/S assessment of the fetus ± NST.

Indications

- Abnormal or atypical NST.
- Post-term pregnancy.
- Decreased fetal movement.
- Any other suggestion of fetal distress or uteroplacental insufficiency.

DDx of Decreased Fetal Movements

DASH
Death of fetus
Amniotic fluid decreased
Sleep cycle of fetus
Hunger/Thirst
Operating Characteristics

- false positive rate ≤30%, false negative rate = 0.1%

Table 9. Scoring of the BPP

<table>
<thead>
<tr>

<td>Fluid pocket of 2 cm in 2 axes</td>
<td>Oligohydramnios</td>
</tr>
<tr>
<td>Breathing</td>
<td>At least one episode of breathing lasting at least 30 s</td>
<td>No breathing</td>
</tr>
<tr>
<td>Limb Movement</td>
<td>Three discrete movements</td>
<td>Two or less</td>
</tr>
<tr>
<td>Fetal Tone</td>
<td>At least one episode of limb extension followed by flexion</td>
<td>No movement</td>
</tr>
</tbody>
</table>

*AFV is a marker of chronic hypoxia, all other parameters indicate acute hypoxia

Interpretation

- 8: perinatal mortality rate 1:1,000; repeat BPP as clinically indicated
- 6: perinatal mortality 31:1,000; repeat BPP in 24 h
- 0-4: perinatal mortality rate 200:1,000; deliver fetus if benefits of delivery outweigh risks

Medical Conditions in Pregnancy

Iron and Folate Deficiency Anemia

Table 10. Iron Deficiency and Folate Deficiency Anemia

<td></td>
<td>325 mg ferrous gluconate = 38 mg elemental Fe²⁺</td>
</tr>
<tr>
<td></td>
<td>Polysaccharide-Iron Complex = 150 mg elemental Fe²⁺</td>
</tr>
<tr>
<td>Complications</td>
<td>Maternal: angina, CHF, infection, slower recuperation, preterm labor</td>
</tr>
<tr>
<td></td>
<td>Fetal: decreased oxygen carrying capacity leading to fetal distress, IUGR, and low birth weight</td>
</tr>
<tr>
<td>Notes</td>
<td>Mother needs 1 g of elemental iron per fetus; this amount exceeds normal stores + dietary intake</td>
</tr>
<tr>
<td></td>
<td>Iron requirements increase during pregnancy due to fetal/placental growth (500 mg), increased maternal RBC mass (500 mg), and losses (200 mg) – more needed for multiple gestations</td>
</tr>
<tr>
<td></td>
<td>Folic acid is necessary for closure of neural tube during early fetal development (by day 28 of gestation)</td>
</tr>
</tbody>
</table>

Diabetes Mellitus

Classification of Diabetes Mellitus

- type 1 and type 2 DM (see Endocrinology, E6)
- GDM: onset of DM during pregnancy

Etiology

- type 1 and type 2 DM
- GDM: usually around 24-28 wk GA, anti-insulin factors produced by placenta and high maternal cortisol levels create increased peripheral insulin resistance → higher fasting glucose → leading to GDM and/or exacerbating pre-existing DM

Epidemiology

- 2-4% of pregnancies are complicated by DM
A. TYPE 1 and TYPE 2 DM

Preconception
- pre-plan and refer to high-risk clinic
- optimize glycemic control
- counsel patient re: potential risks and complications
- evaluate for diabetic retinopathy, neuropathy, CAD

Pregnancy
- if already on oral medication, generally switch to insulin therapy
  - continuing glyburide or metformin controversial
  - teratogenicity unknown for other oral anti-hyperglycemics
- tight glycemic control
  - insulin dosage may need to be adjusted in type 2 due to increased demand and increased insulin resistance
- monitor as for normal pregnancy plus initial 24 h urine protein and creatinine clearance, retinal exam, HbA1c
  - HbA1c: >140% of pre-pregnancy value associated with increased risk of spontaneous abortion and congenital malformations
- increased fetal surveillance (BPP, NST), consider fetal ECHO to look for cardiac abnormalities

Labor
- timing of delivery depends on fetal and maternal health and risk factors (i.e. must consider size of baby, lung maturity, maternal blood glucose, and blood pressure control)
- can wait for spontaneous labor if blood glucose well-controlled and BPP normal
- induce by 40 wk
- type of delivery
  - increased risk of cephalopelvic disproportion (CPD) and shoulder dystocia with babies >4,000 g (8.8 lbs)
  - elective C/S for predicted birthweight >4,500 g (9.9 lbs) (controversial)
- monitoring
  - during labor monitor blood glucose q1h with patient on insulin and dextrose drip
  - aim for blood glucose between 60-120 mg/dL to reduce the risk of neonatal hypoglycemia

Postpartum
- insulin requirements dramatically drop with expulsion of placenta (source of insulin antagonists)
- no insulin is required for 48-72 h postpartum in most type 1 DM
- monitor glucose q6h, restart insulin at two-thirds of pre-pregnancy dosage when glucose >144 mg/dL.

B. GESTATIONAL DIABETES MELLITUS

Screening and Diagnosis
- all pregnant women between 24-28 wk GA (or at any stage if high risk)
- 2 screening options
  - 1-step screening with fasting 75 g OGTT; GDM if ≥1 of:
    - FPG ≥90 mg/dL
    - 1h PG ≥180 mg/dL
    - 2h PG ≥153 mg/dL
  - 2-step screening
    - Step 1: Perform a random nonfasting 50 g OGCT
      - 1h PG <140 mg/dL is normal
      - 1h PG ≥200 mg/dL is GDM
      - if 1h PG 140-200 mg/dL, proceed to Step 2
    - Step 2: Perform a fasting 75 g OGTT, GDM if ≥1 of:
      - FPG ≥95 mg/dL
      - 1h PG ≥190 mg/dL
      - 2h PG ≥162 mg/dL

Management
- first line is management through diet modification and increased physical activity
- initiate insulin therapy if glycemic targets not achieved within 2 wk of lifestyle modification alone
- glycemic targets: FPG <95 mg/dL, 1h PG <140 mg/dL, 2h PG <120 mg/dL.
• use of oral agents can be used in pregnancy but is off-label and should be discussed with patient
• stop insulin and diabetic diet postpartum
• follow-up with 75 g OGTT 6 wk-6 mo postpartum

Prognosis
• most maternal and fetal complications are related to hyperglycemia and its effects

Long-Term Maternal Complications
• type 1 and type 2 DM: risk of progressive retinopathy and nephropathy
• GDM: 50% risk of developing type 2 DM in next 20 yr

</table>

Hypertension in Pregnancy

• hypertensive disorders of pregnancy are classified as either pre-existing or gestational HTN

PRE-EXISTING HYPERTENSION

Definition
• HTN (>140/90) prior to 20 wk GA, persisting >7 wk postpartum
• essential HTN is associated with an increased risk of gestational HTN, abruptio placenta, IUGR, and IUFD

GESTATIONAL HYPERTENSION

Definition
• sBP >140 or dBP >90 developing after 20th wk GA in a woman known to be normotensive before pregnancy

Risk Factors
• maternal factors
  ▪ primigravida (80-90% of gestational HTN)
  ▪ first conception with a new partner
  ▪ PMHx or FHx of gestational HTN
  ▪ DM, chronic HTN, or renal insufficiency
  ▪ Antiphospholipid syndrome
  ▪ extremes of maternal age (<18 or >35 yr)
• fetal factors
  ▪ IUGR or oligohydramnios, GTN, multiple gestation, fetal hydrops
  ▪ previous stillbirth or IUFD

Ominous Symptoms of HTN in Pregnancy
• RUQ pain, headache, and visual disturbances
Clinical Evaluation of Hypertension in Pregnancy

- In general, clinical evaluation should include the mother and fetus

**Evaluation of Mother**
- Body weight
- Central nervous system
  - Presence and severity of headache
  - Visual disturbances – blurring, scotomata
  - Tremulousness, irritability, somnolence
  - Hyperreflexia
- Hematologic
  - Bleeding, petechiae
- Hepatic
  - RUQ or epigastric pain
  - Severe N/V
- Renal
  - Urine output and color
  - Non-dependent edema (i.e. hands and face)

**Evaluation of Fetus**
- Fetal movement
- Fetal heart rate tracing – NST
- Ultrasound for growth
- BPP
- Doppler flow studies

Laboratory Evaluation of Gestational Hypertension
- Hemoglobin, platelets, blood film
- PTT, INR, fibrinogen – especially if surgery or regional anesthetics are planned
- ALT, AST, LDH, bilirubin
- Proteinuria, creatinine, uric acid
- 24 h urine collection for total protein and creatinine clearance or spot urine protein:creatinine ratio

Complications
- Maternal
  - Liver and renal dysfunction
  - Seizure
  - Abruptio placenta
  - Left ventricular failure/pulmonary edema
  - DIC (release of placental thromboplastin consumptive coagulopathy)
  - HELLP syndrome
    - Treat with FFP infusion or plasma exchange
  - Hemorrhagic stroke (50% of deaths)
- Fetal (2nd to placental insufficiency)
  - IUGR, prematurity, abruptio placenta, IUFD

Management
- Target a BP of 130-155/80-105 in women without comorbidities or 130-139/80-89 in women with comorbidities
- For both pre-existing and gestational HTN, labetalol 100-400 mg PO bid-tid, nifedipine (PA tablets 10-20 mg PO bid-tid or XL preparation 20-60 mg PO daily), or α-methyldopa 250-500 mg PO tid-qid
- For severe HTN (BP >160/110), give one of
  - Labetalol 20 mg IV then 20-80 mg IV q30min (max 300 mg)
  - Nifedipine 5-10 mg capsule q30min
  - Hydralazine 5 mg IV, repeat 5-10 mg IV q30min (max 20 mg IV)
- No ACE inhibitors, ARBs, diuretics, prazosin, or atenolol
- Pre-existing HTN and gestational HTN without any deterioration can be followed until 37 wk then decide to induce shortly thereafter

PREECLAMPSIA

**Definition**
- Pre-existing or gestational HTN with new onset proteinuria or adverse conditions

**Risk Factors**
- Nulliparity
- Preclampsia in a previous pregnancy
- Age >40 yr or <18 yr
- FHx of preeclampsia
• chronic HTN
• chronic renal disease
• antiphospholipid antibody syndrome or inherited thrombophilia
• vascular or connective tissue disease
• DM (pre-gestational and gestational)
• high BMI
• hydrops fetalis
• unexplained fetal growth restriction
• abruptio placentae
• there is a potential for further deterioration to severe preeclampsia as defined above
• the adverse conditions are many and include both maternal and fetal issues

Management
• management will depend on GA, possible threat of seizures (check reflexes)
• if stable and no adverse factors, may admit and follow, ± decide to deliver as approaching 34-36 wk (must weigh risks of fetal prematurity vs. risks of developing severe preeclampsia/ eclampsia)
• for severe preeclampsia, stabilize and deliver
• if severe preeclampsia, during labor, increase maternal monitoring: hourly input and output, urine dip q12h, hourly neurological vitals, and increase fetal monitoring (continuous FHR monitoring)
• antihypertensive therapy
  • lowering BP decreases the risk of stroke
  • hydralazine 5-10 mg IV bolus over 5 min q15-30min as necessary
  • labetalol 20-50 mg IV q10min
  • 2nd line: nifedipine 10-20 mg PO q20-60min
• seizure prevention
  • MgSO₄
  • postpartum management
  • risk of seizure highest in first 24 h postpartum – continue MgSO₄ for 12-24 h after delivery
  • vitals q1h
  • consider HELLP syndrome in toxic patients
  • most return to a normotensive BP within 2 wk

ECLAMPSIA

Definition
• the occurrence of one or more generalized convulsions and/or coma in the setting of preeclampsia and in the absence of other neurologic conditions

Epidemiology
• an eclamptic seizure occurs in approximately 0.5% of mildly preeclamptic women and 2-3% of severely preeclamptic women

Risk Factors
• same as risk factors for preeclampsia

Clinical Manifestations
• eclampsia is a clinical diagnosis
• typically tonic-clonic and lasting 60-75 s
• one of the signs of an impending seizure is hyperreflexia
• symptoms that may occur before the seizure include persistent frontot central headache, blurred vision, photophobia, right upper quadrant or epigastric pain, and altered mental status
• in up to one third of cases, there is no proteinuria or blood pressure is <140/90 mmHg prior to the seizure
• in general, women with typical eclamptic seizures who do not have focal neurologic deficits or prolonged coma do not require diagnostic evaluation including imaging

Management
• ABCs
• roll patient into LLDP
• supplemental O₂ via face mask to treat hypoxemia due to hypoventilation during convulsive episode
• aggressive antihypertensive therapy for sustained diastolic pressures ≥105 mmHg or systolic blood pressures ≥160 mmHg with hydralazine or labetalol
• prevention of recurrent convulsions: to prevent further seizures and the possible complications of repeated seizure activity (e.g. rhabdomyolysis, metabolic acidosis, aspiration pneumonitis, etc.)
• MgSO₄ is now the drug of choice, with previously used agents including diazepam and phenytoin

Preeclampsia Investigations
• CBC
• Liver enzymes
• INR and aPTT
• Cr
• Uric acid
• LDH
• Albumin
• Bilirubin
• Urine (dip ± 24 h collection or protein/creatinine ratio)

HELLP Syndrome
Hemolysis
Elevated Liver enzymes
Low Platelets

Differential Diagnosis of Cause for Seizure in a Pregnant Woman
• Stroke
• Hypertensive disease (hypertensive encephalopathy, pheochromocytoma)
• Space-occupying lesion of the CNS
• Metabolic disorders (hypoglycemia, SIADH)
• Infection (meningitis, encephalitis)
• Thrombotic thrombocytopenic purpura or thrombophilia
• Idiopathic epilepsy
• Use of illicit drugs
• Cerebral vasculitis

Note
Eclampsia prior to 20 wk of gestation is rare and should raise the possibility of an underlying molar pregnancy or antiphospholipid syndrome

MgSO₄ Toxicity
• Flushing
• Hyporeflexia
• Somnolence
• Respiratory and cardiac depression
• Weakness
Note: Increased risk of toxicity with concurrent calcium channel blocker use or renal disease

Treatment
• Stop MgSO₄
• Calcium gluconate 10% in 10 mL IV
the definitive treatment of eclampsia is DELIVERY, irrespective of gestational age, to reduce the risk of maternal morbidity and mortality from complications of the disease. Mode of delivery is dependent on clinical situation and fetal-maternal condition.

**Nausea and Vomiting**

**Epidemiology**
- affects 50-90% of pregnant women
- often limited to T1 but may persist

**Management**
- rule out other causes of N/V
- weigh frequently, assess level of hydration, test urine for ketones
- **non-pharmacological**
  - avoid mixing fluids and solids, frequent small meals
  - stop prenatal vitamins (folic acid must continue until >12 wk)
  - increase sleep/rest
  - ginger (maximum 1,000 mg/d)
  - acupuncture, acupressure
- **pharmacological**
  - first line: Diclectin® (10 mg doxylamine succinate with vitamin B₆) 4 tablets PO daily to maximum of 8 tablets
  - if no improvement, try dimenhydrinate (50-100 mg q4-6h PO), followed by hydroxyzine, pyridoxine, phenothiazine, or metoclopramide
  - vitamin B₆ lollipops
  - if patient dehydrated, assess fluid replacement needs and resuscitate accordingly
- **severe/refractory:**
  - consider homecare with IV fluids and parenteral anti-emetics, hospitalization

**Hyperemesis Gravidarum**

**Definition**
- intractable N/V, usually presents in T1 then diminishes; occasionally persists throughout pregnancy
- affects ~1% of pregnancies

**Etiology**
- multifactorial with hormonal, immunologic, and psychologic components
- rapidly rising β-hCG ± estrogen levels may be implicated

**Investigations**
- rule out systemic causes: GI inflammation, pyelonephritis, thyrotoxicosis
- rule out obstetrical causes: multiple gestation, GTN, HELLP syndrome
- CBC, electrolytes, BUN, creatinine, LFTs, urinalysis
- ultrasound

**Management**
- thiamine supplementation may be indicated
- **non-pharmacological** (see Nausea and Vomiting)
- **pharmacological options**
  - Diclectin® (for dosage, see Nausea and Vomiting)
  - Dimenhydrinate can be safely used as an adjunct to Diclectin® (1 suppository bid or 25 mg PO qid)
  - other adjuncts: hydroxyzine, pyridoxine, phenothiazine, metoclopramide
  - also consider: ondansetron or methylprednisolone
  - if severe: admit to hospital, NPO initially then small frequent meals, correct hypovolemia, electrolyte disturbance, and ketosis, TPN (if very severe) to reverse catabolic state

**Complications**
- maternal
  - dehydration, electrolyte and acid-base disturbances
  - Mallory-Weiss tear
  - Wernicke's encephalopathy, if protracted course
  - death
- fetal: usually none, IUGR is 15x more common in women losing >5% of pre-pregnancy weight
Urinary Tract Infection

Etiology
• increased urinary stasis from mechanical and hormonal (progesterone) factors
• organisms include GBS as well as those that occur in non-pregnant women

Epidemiology
• most common medical complication of pregnancy
• asymptomatic bacteriuria in 2-7% of pregnant women, more frequently in multiparous women
• note: asymptomatic bacteriuria should be treated in pregnancy due to increased risk of pyelonephritis

Clinical Features
• may be asymptomatic
• dysuria, urgency, and frequency in cystitis
• fever, flank pain, and costovertebral angle tenderness in pyelonephritis

Investigations
• urinalysis, urine C&S
• cystoscopy, and renal function tests in recurrent infections

Management
• uncomplicated UTI
  ▪ first line: amoxicillin (250-500 mg PO q8h x 7 d)
  ▪ alternatives: nitrofurantoin (100 mg PO bid x 7 d)
  ▪ follow with monthly urine cultures
• pyelonephritis
  ▪ hospitalization and IV antibiotics

Prognosis
• complications if untreated: acute cystitis, pyelonephritis, and possible preterm labor
• recurrence is common

Infections During Pregnancy

Table 12. Infections During Pregnancy

<table>

<tr>
<td><em>Toxoplasmosis</em></td>
<td>Protozoa (Toxoplasma gondii)</td>
<td>To mom: raw meat, unpasteurized goat’s milk, cat feces/urine To baby: transplacental</td>
<td>T3 (but most severe if infected in T1); only concern if primary infection during pregnancy</td>
<td>Congenital toxoplasmosis (chorioretinitis, hydrocephaly, intracranial calcification, MR, microcephaly) NB: 75% initially asymptomatic at birth</td>
<td>Majority subclinical; may have flu-like symptoms</td>
<td>IgM and IgG serology; PCR of amniotic fluid</td>
<td>Self-limiting in mother; spiramycin decreases fetal morbidity but not rate of transmission</td>
</tr>
</tbody>
</table>

* Indicates TORCH infection

---

**Venous Thromboembolism**

**Epidemiology**
- incidence 0.5-3/1,000 pregnancies occurring with approximately equal frequency in all three trimesters and postpartum

**Risk Factors**
- previous VTE, age >35, obesity, infection, bedrest/immobility, shock/dehydration, thrombophilies (see Hematology, H33)
Table 13. Risk Factors for VTE Specific to Pregnancy

<table>
<thead>
<tr>

</tr>
<tr>
<td>• unexplained spontaneous fetal loss</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Investigations
• duplex venous Doppler sonography for DVT
• CXR and V/Q scan or spiral CT for PE

Management
• before initiating treatment, obtain a baseline CBC including platelets, and aPTT
• warfarin is contraindicated during pregnancy due to its potential teratogenic effects
• unfractionated heparin
  ▪ bolus of 5,000 IU followed by an infusion of ~30,000 IU/24h
  ▪ measure aPTT 6 h after the bolus
  ▪ maintain aPTT at a therapeutic level (1.5-2x normal)
  ▪ repeat q24h once therapeutic
  ▪ heparin-induced thrombocytopenia (HIT) uncommon (3%) but serious complication
  ▪ LMWH can also be used in pregnancy
• compression stockings
• poor evidence to support a recommendation for or against avoidance of prolonged sitting
• VTE prophylaxis
  ▪ women on long-term anticoagulation: full therapeutic anticoagulation throughout pregnancy and for 6-12 wk postpartum
  ▪ women with a non-active PMHx of VTE: unfractionated heparin regimens suggested
• routine VTE prophylaxis
  ▪ insufficient evidence in pregnancy to recommend routine use of LMWH
• current prophylaxis regimens for acquired thrombophilias (e.g. APS syndrome) include low dose Aspirin® in conjunction with prophylactic heparin

Bleeding in Pregnancy Definitions
• First trimester bleeding: vaginal bleeding within the first 12 wk
• Second trimester bleeding: <20 wk

Bleeding in Pregnancy Definitions
• Physiologic bleeding: spotting, due to implantation of placenta – reassure and check serial h-hCGs
• Abortion (threatened, inevitable, incomplete, complete) (see Gynecology, Hydatidiform Mole GY45)
• Trauma (post-coital or after pelvic exam)
• Genital lesion (e.g. cervical polyp, neoplasms)

Differential Diagnosis
• Gyneco流星ology, Hydatidiform Mole GY45

First and Second Trimester Bleeding

Approach to the Patient with Bleeding in T1/T2
• history
  ▪ risk factors for ectopic pregnancy (previous ectopic pregnancies, history of STD/PID, IUD use, previous pelvic surgery, smoking)
  ▪ previous spontaneous abortion
  ▪ recent trauma
  ▪ characteristics of the bleeding (including any tissue passed)
  ▪ characteristics of the pain (cramping pain suggests SA)
  ▪ history of coagulopathy
  ▪ gynecological/obstetric history
  ▪ dizziness (significant blood loss, may be associated with ruptured ectopic)
  ▪ fever (may be associated with septic abortion)
• physical
  ▪ vitals (including orthostatic changes)
  ▪ abdomen (SFH, tenderness, presence of contractions)
  ▪ perineum (signs of trauma, genital lesions)
  ▪ speculum exam (cervical os open or closed, presence of active bleeding/clots/tissue)
  ▪ pelvic exam (uterine size, adnexal mass, uterine/adnexal tenderness)
Investigations
- β-hCG (lower than expected for GA in spontaneous abortion, ectopic pregnancy)
- U/S (confirm intrauterine pregnancy and fetal viability)
- CBC
- group and screen

Treatment
- IV resuscitation for hemorrhagic shock
- treat the underlying cause

Spontaneous Abortions
- see Termination of Pregnancy, OB11, for therapeutic abortions

Table 14. Classification of Spontaneous Abortions

c) D&C ± oxytocin |
| Incomplete | Extremely heavy bleeding and cramps ± passage of tissue noticed | Cervix open U/S products of conception | a) Watch and wait  
b) Misoprostol 400-800 µg PO/PV  
c) D&C ± oxytocin |
| Complete   | Bleeding and complete passage of sac and placenta | Cervix open U/S no products of conception | No D&C – expectant management |
| Missed     | No bleeding (fetal death in utero)           | Cervix closed U/S may show SGA, no fetal heart activity; nonviable fetus | a) Watch and wait  
b) Misoprostol 400-800 µg PO/PV  
c) D&C ± oxytocin |
| Recurrent  | ≥3 consecutive spontaneous abortions           | Evaluate mechanical, genetic, environmental, and other risk factors |
| Septic     | Contents of uterus infected – infrequent     | D&C  
IV broad spectrum antibiotics |

Ectopic Pregnancy

Definition
- embryo implants outside of the endometrial cavity

Epidemiology
- 1/100 pregnancies
- fourth leading cause of maternal mortality, leading cause of death in first trimester
- increase in incidence over the last 3 decades
- three commonest locations for ectopic pregnancy: ampullary (70%), isthmic (12%), fimbrial (11%)

Etiology
- 50% due to damage of fallopian tube cilia following PID
- intrinsic abnormality of the fertilized ovum
- conception late in cycle
- transmigration of fertilized ovum to contralateral tube

Clinical Features of Ectopic Pregnancy
- 4Ts and 1S
  - Temperature >100.4ºF (20%)  
  - Tenderness: abdominal (90%) ± rebound (45%)  
  - Tenderness on bimanual examination, cervical motion tenderness  
  - Tissue: palpable adnexal mass (50%) (half have contralateral mass due to lutein cyst)  
  - Signs of pregnancy (e.g. Chadwick’s sign, Hegar’s sign)  

More than half of patients with ectopic pregnancy have no risk factors
Figure 3. Sites of ectopic pregnancy implantation
Ampullary (70%) >> isthmal (12%) > fimbrial (11%) > ovarian (3%) > interstitial (2%) > abdominal (1%)

Risk Factors
• previous ectopic pregnancy
• gynecologic
  - IUD use – increased risk of ectopic if pregnancy occurs
  - history of PID (especially infection with C. trachomatis), salpingitis
  - infertility
  - clomiphene citrate (for induction of ovulation)
• previous procedures
  - any surgery on fallopian tube (for previous ectopic, tubal ligation, etc.)
  - abdominal surgery for ruptured appendix, etc.
  - IVF pregnancies following ovulation induction (7% ectopic rate)
• smoking
• structural
  - uterine leiomyomas
  - adhesions
  - abnormal uterine anatomy (e.g. T-shaped uterus)

Investigations
• serial β-hCG levels; normal doubling time with intrauterine pregnancy is 1.6-2.4 d in early pregnancy
  - rise of <20% of β-hCG is 100% predictive of a non-viable pregnancy
  - prolonged doubling time, plateau, or decreasing levels before 8 wk implies nonviable gestation but does not provide information on location of implantation
  - 85% of ectopic pregnancies demonstrate abnormal β-hCG doubling
• ultrasound
  - U/S is only definitive if fetal cardiac activity is detected in the tube or uterus
  - specific finding on transvaginal U/S is a tubal ring
• laparoscopy (for definitive diagnosis)

Treatment
• goals of treatment: conservative (preserve tube if possible), maintain hemodynamic stability
• surgical (laparoscopy)
  - linear salpingostomy if tube salvageable
  - salpingectomy if tube damaged or ectopic is ipsilateral recurrence
  - 15% risk of persistent trophoblast; must monitor β-hCG titres weekly until they reach non-detectable levels
  - consider Rhogam® if Rh negative
  - may require laparotomy if patient is unstable, extensive abdominal surgical history, etc.
• medical = methotrexate (for indications see Figure 4)
  - use 50 mg/m² body surface area; given in a single IM dose
  - this is 1/5 to 1/6 chemotherapy dose, therefore minimal side effects (reversible hepatic dysfunction, diarrhea, gastritis, dermatitis)

DDx of Lower Abdominal Pain
• Urinary tract: UTI, kidney stones
• GI: diverticulitis, appendicitis
• Gyn: endometriosis, PID, fibroid (degenerating, infarcted, torsion), ovarian torsion, ovarian neoplasm, ovarian cyst, pregnancy-related

If Ectopic Pregnancy Ruptures
• Acute abdomen with increasing pain
• Abdominal distention
• Shock
follow β-hCG levels weekly until β-hCG is non-detectable
• plateau or rising levels suggest persisting trophoblastic tissue (requires further treatment)
• 82-95% success rate but up to 25% will require a second dose
• tubal patency following methotrexate treatment approaches 80%

Prognosis
• 9% of maternal deaths during pregnancy
• 40-60% of patients will become pregnant again after surgery
• 10-20% will have subsequent ectopic pregnancy

Interventions for Tubal Ectopic Pregnancy
Cochrane DB Syst Rev 2007;1:CD000324
Study: Cochrane Review of randomized controlled trials comparing treatments in women with tubal ectopic pregnancy
Patients: Women with a diagnosis of tubal ectopic pregnancy
Intervention: Surgery (salpingectomy/salpingostomy by open surgery or by laparoscopy), medical treatment, and expectant management
Main Outcome: Primary treatment success, defined as an uneventful decline in serum β-hCG to undetectable levels by the initial treatment
Results: Intramuscular MTX therapy and salpingostomy yielded similar treatment success rates (82-95% for MTX therapy vs. 80-92% for salpingostomy).

Antepartum Hemorrhage

Definition
• vaginal bleeding from 20 wk to term

Differential Diagnosis
• bloody show (shedding of cervical mucous plug) – most common etiology in T3
• placenta previa
• abruptio placenta – most common pathological etiology in T3
• vasa previa
• cervical lesion (cervicitis, polyp, ectropion, cervical cancer)
• other: bleeding from bowel or bladder, placenta accreta, abnormal coagulation

Table 15. Comparison of Placenta Previa vs. Abruptio Placentae

</table>

| Bleeding         | PAINLESS | PAINFUL |

Key Questions to Ask in Antepartum Hemorrhage
• How much bleeding?
• Are there contractions/cramping/pain?
• Description? Color, clotting, etc.

Levels of Abnormal Placental Invasion
Placenta Accreta: AT myometrium (most common)
Placenta Increta: INTO myometrium
Placenta Percreta: PASSES through myometrium
Placenta Previa

Definition
• placenta implanted in the lower segment of the uterus, presenting ahead of the leading pole of the fetus
• the distance of the placental edge from the internal os is described in “millimeters away” from the internal os or “millimeters of overlap” over the internal os
• greater than 20 millimeters of overlap over the internal os in the third trimester of pregnancy is highly predictive of the need for a C/S
• any degree of overlap after 35 wk is an indication for a C/S

Clinical Features
• PAINLESS bright red vaginal bleeding (recurrent), may be minimized and cease spontaneously, but can become catastrophic
• mean onset of bleeding is 30 wk GA, but onset depends on degree of previa
• physical exam
  ▪ uterus soft and non-tender
  ▪ presenting fetal part high or displaced
  ▪ FHR usually normal
  ▪ shock/anemia correspond to degree of apparent blood loss
• complications
  ▪ fetal
    • perinatal mortality low but still higher than with a normal pregnancy
    • prematurity (bleeding often dictates early C/S)
    • intrauterine hypoxia (acute or IUGR)
    • fetal malpresentation
    • PPROM
    • risk of fetal blood loss from placenta, especially if incised during C/S
  ▪ maternal
    • <1% maternal mortality
    • hemorrhage and hypovolemic shock, anemia, acute renal failure, pituitary necrosis (Sheehan syndrome)
    • placenta accreta – especially if previous uterine surgery, anterior placenta previa
    • hysterectomy

Investigations
• transvaginal U/S is more accurate than transabdominal U/S at diagnosing placenta previa at any gestational age
• if the placenta lies between 20 mm of overlap and 20 mm away from the internal os after 26 wk regular transvaginal ultrasounds should be repeated at regular intervals – continued change in the placental location is likely

Management
• goal: keep pregnancy intrauterine until the risk of delivery < risk of continuing pregnancy
  ▪ stabilize and monitor
    • maternal stabilization: large bore IV with hydration, O₂ for hypotensive patients
    • maternal monitoring: vitals, urine output, blood loss, blood work (hematocrit, CBC, INR/PTT, platelets, fibrinogen, FDP, type and cross match)
    • electronic fetal monitoring
    • U/S assessment: when fetal and maternal condition permit, determine fetal viability, gestational age, and placental status/position
• Rhogam® if mother is Rh negative
  ▪ Kleihauer-Betke test to determine extent of fetomaternal transfusion so that appropriate dose of Rhogam® can be given
• GA <37 wk and minimal bleeding: expectant management
  ▪ admit to hospital
  ▪ limited physical activity, no douches, enemas, or sexual intercourse
  ▪ consider corticosteroids for fetal lung maturity
  ▪ delivery when fetus is mature or hemorrhage dictates
• GA ≥37 wk, profuse bleeding, or L/S ratio is >2:1 – deliver by C/S
Abruptio Placentae

Clinical Features
- classification
  - total (fetal death inevitable) vs. partial
  - external/revealed/apparent: blood dissects downward toward cervix
  - internal/concealed (20%): blood dissects upward toward fetus
  - most are mixed
- presentation
  - PAINFUL (80%) vaginal bleeding (bleeding not always present if abruption is concealed), uterine tenderness, uterine contractions
  - pain: sudden onset, constant, localized to lower back and uterus
  - shock/anemia out of proportion to apparent blood loss
  - ± fetal distress, fetal demise (15% present with demise), bloody amniotic fluid (fetal presentation typically normal)
  - ± coagulopathy

Complications
- fetal complications: perinatal mortality 25-60%, prematurity, intrauterine hypoxia
- maternal complications: <1% maternal mortality, DIC (in 20% of abruptions), acute renal failure, anemia, hemorrhagic shock, pituitary necrosis (Sheehan syndrome), amniotic fluid embolus

Investigations
- clinical diagnosis, U/S not sensitive for diagnosing abruption (sensitivity = 15%)

Management
- maternal stabilization: large bore IV with hydration, O₂ for hypotensive patients
- maternal monitoring: vitals, urine output, blood loss, blood work (hematocrit, CBC, PTT/PT, platelets, fibrinogen, FDP, type and cross match)
- EFM
- blood products on hand (red cells, platelets, cryoprecipitate) because of DIC risk
- Rhogam™ if Rh negative
  - Kleihauer-Betke test may confirm abruption
- mild abruption
  - GA <37 wk: use serial Hct to assess concealed bleeding, deliver when fetus is mature or when hemorrhage dictates
  - GA ≥37 wk: stabilize and deliver
- moderate to severe abruption
  - hydrate and restore blood loss and correct coagulation defect if present
  - vaginal delivery if no contraindication and no evidence of fetal or maternal distress OR fetal demise
  - C/S if live fetus and fetal or maternal distress develops with fluid/blood replacement, labor fails to progress or if vaginal delivery otherwise contraindicated

Vasa Previa

Definition
- unprotected fetal vessels pass over the cervical os; associated with velamentous insertion of cord into membranes of placenta or succenturiate (accessory) lobe

Epidemiology
- 1 in 5,000 deliveries – higher in twin pregnancies

Clinical Features
- PAINLESS vaginal bleeding and fetal distress (tachy- to bradyarrhythmia)
- 50% perinatal mortality, increasing to 75% if membranes rupture (most infants die of exsanguination)

Investigations
- Apt test (NaOH mixed with the blood) can be done immediately to determine if the source of bleeding is fetal (supernatant turns pink) or maternal (supernatant turns yellow)
- Wright stain on blood smear and look for nucleated red blood cells (in cord, not maternal blood)

Management
- emergency C/S (since bleeding is from fetus, a small amount of blood loss can have catastrophic consequences)
Multiple Gestation

Epidemiology
• incidence of twins is 1/80 and triplets 1/6,400 in North America
• 2/3 of twins are dizygotic (fraternal)
  ▪ risk factors for dizygotic twins: IVF, increased maternal age, newly discontinued OCP, ethnicity (e.g. certain African regions)
• monozygous twinning occurs at a constant rate worldwide (1/250)
• determine zygosity by number of placentas, thickness of membranes, sex, blood type

Clinical Features

*Most common cause of perinatal mortality in multiple gestation

Management
• U/S determination of choriocity must be done within first trimester (ideally 8-12 wk GA)
• increased antenatal surveillance
  ▪ serial U/S q2-3wk from 28 wk GA to assess growth (uncomplicated diamniotic dichorionitic)
  ▪ increased frequency of ultrasounds in monochorionic diamniotic and monochorionic monoamniotic twins
  ▪ Doppler flow studies weekly if discordant fetal growth (>30%)
  ▪ BPP as needed
• may attempt vaginal delivery if twin A presents as vertex, otherwise C/S (40-50% of all twin deliveries, 15% of cases have twin A delivered vaginally and twin B delivered by C/S)
• mode of delivery depends on fetal weight, GA, presentation

![Figure 6. Classification of twin pregnancies](image-url)
Twin-Twin Transfusion Syndrome

Epidemiology
• 10% of monochorionic twins
• concern if >30% discordance in estimated fetal weight

Etiology
• arterial blood from donor twin passes through placenta into vein of recipient twin

Clinical Features
• donor twin: IUGR, hypovolemia, hypotension, anemia, oligohydramnios
• recipient twin: hypervolemia, HTN, CHF, polycythemia, edema, polyhydramnios, kernicterus in neonatal period

Investigations
• detected by U/S screening, Doppler flow analysis

Management
• therapeutic serial amniocentesis to decompress polyhydramnios of recipient twin and decrease pressure in cavity and on placenta
• intrauterine blood transfusion to donor twin if necessary
• laparoscopic occlusion of placental vessels

Growth Discrepancies

Intrauterine Growth Restriction

Definition
• infant weight <10th percentile for GA or <2,500 g

Etiology/Risk Factors
• maternal causes
  ▪ malnutrition, smoking, drug abuse, alcoholism, cyanotic heart disease, type 1 DM, SLE, pulmonary insufficiency, previous IUGR
• maternal-fetal
  ▪ any disease causing placental insufficiency
  ▪ includes gestational HTN, chronic HTN, chronic renal insufficiency, gross placental morphological abnormalities (infarction, hemangiomas)
• fetal causes:
  ▪ TORCH infections, multiple gestation, congenital anomalies

Clinical Features
• symmetric/type I (20%): occurs early in pregnancy
  ▪ inadequate growth of head and body
  ▪ head:abdomen ratio may be normal (>1 up to 32 wk; =1 at 32-34 wk; <1 after 34 wk GA)
  ▪ usually associated with congenital anomalies or TORCH infections
• asymmetric/type II (80%): occurs late in pregnancy
  ▪ brain is spared, therefore head:abdomen ratio increased
  ▪ usually associated with placental insufficiency
  ▪ more favorable prognosis than type I
  ▪ complications
    ▪ prone to meconium aspiration, asphyxia, polycythemia, hypoglycemia, and mental retardation
    ▪ greater risk of perinatal morbidity and mortality

Investigations
• SFH measurements at every antepartum visit
• if mother at high risk or SFH lags >2 cm behind GA
  ▪ U/S for biparietal diameter, head and abdominal circumference, femur length, fetal weight, and AFV (decrease associated with IUGR)
  ▪ ± BPP
  ▪ Doppler analysis of umbilical cord blood flow

Management
• prevention via risk modification prior to pregnancy is ideal
• modify controllable factors: smoking, alcohol, nutrition, and treat maternal illness
• bed rest in LLDP
• serial BPP (monitor fetal growth) and determine cause of IUGR, if possible
• delivery when extrauterine existence is less dangerous than continued intrauterine existence (abnormal function tests, absent growth, severe oligohydramnios) especially if GA >34 wk
• liberal use of C/S since IUGR fetus withstands labor poorly
Macrosomia

Definition
- infant weight >90th percentile for a particular GA or >4.000 g

Etiology/Risk Factors
- maternal obesity, GDM, past history of macrosomic infant, prolonged gestation, multiparity

Clinical Features
- increased risk of perinatal mortality
- CPD and birth injuries (shoulder dystocia, fetal bone fracture) more common
- complications of DM in labor (see Table 11, OB15)

Investigations
- serial SFH
- further investigations if mother at high risk or SFH >2 cm ahead of GA
- U/S predictors
  - polyhydramnios
  - third trimester AC >1.5 cm/wk
  - HC/AC ratio <10th percentile
  - FL/AC ratio <20th percentile

Management
- prophylactic C/S is a reasonable option where EFW >5,000 g in non-diabetic woman and EFW >4,500 g in diabetic woman
  - no evidence that prophylactic C/S improves outcomes
- early induction of labor is not recommended for non-diabetic mothers
- risks and benefits of early induction (risk of C/S vs. risk of dystocia) must be weighed in diabetic mothers, as current research is unclear

Polyhydramnios/Oligohydramnios

Prognosis

- Polyhydramnios: 2-5 fold increase in risk of perinatal mortality
- Oligohydramnios: Poorer with early onset

High mortality related to congenital malformations and pulmonary hypoplasia when diagnosed during T2

Normal Labor and Delivery

Definition of Labor

- true labor: regular, painful contractions of increasing intensity associated with progressive dilatation and effacement of cervix and descent of presenting part, or progression of station
  - preterm (>20 to <36+6 wk GA)
  - term (37-41+6 wk GA)
  - postterm (>42 wk GA)
- false labor: Braxton-Hicks contractions
  - irregular contractions, with unchanged intensity and long intervals, occur throughout pregnancy and not associated with any dilatation, effacement, or descent
  - often relieved by rest or sedation

The Cervix

- dilatation: latent phase: 0-3 cm; active phase: 4-10 cm
- effacement: thinning of the cervix by percentage or length of cervix (cm)
- consistency: firm vs. soft
- position: posterior vs. anterior
- application: contact between the cervix and presenting part (i.e. well or poorly applied)
  - see Bishop score (Table 22, OB35)

The Fetus

- fetal lie
  - orientation of the long axis of the fetus with respect to the long axis of the uterus (longitudinal, transverse, oblique)

- fetal presentation
  - fetal part presenting at pelvic outlet
    - breech (complete, frank, footling) (see Figure 9, OB39)
    - cephalic (vertex, face, asynclitic)
    - transverse (shoulder)
  - compound (fetal extremity prolapses along with presenting part)
  - all except vertex are considered malpresentations (see High Risk Labor and Delivery, OB37)

- fetal position
  - position of presenting part of the fetus relative to the maternal pelvis
    - OA: most common presentation (“normal”) – left OA most common
    - OP: most rotate spontaneously to OA; may cause prolonged second stage of labor
  - OT: leads to arrest of dilatation
  - normally, fetal head enters maternal pelvis and engages in OT position
  - subsequently rotates to OA position (or OP in a small percentage of cases)

Maternal Triage Assessment

ID: Age, GPA, EDC, GA, GBS, Rh, Ser CC
HP: 4 key questions:
- Contractions: Since when, how close (q x min), how long (x s), how painful
- Bleeding: Since when, how much (pads), color (pinkish mucus=show vs. brownish vs. bright red ± clots), pain?, last U/S, trauma/intercourse?
- Fluid (ROM): Since when, large gush vs. trickle, soaked pants?, clear vs. green vs. red?, continuous?
- FM: As much as usual?, When last movement?, Kick counts (lie still for 1-2 h, cold juice, feel FM – should have 6 movements in 2 h)

PregHx: Any complications (HTN, GDM, infections), IPI/FTS screening, last U/S (BPP score, growth/estimated fetal weight, position), last vaginal exam
POBHx: Every previous pregnancy and outcome: Year, SVD/CS/miscarriage-abortion, baby size, length of labor, use of vacuum or forceps, complications
PMHx, Meds, Allergies, SHx
O/E: Maternal vitals, fetal heart tracing (baseline, variability, presence of accelerations/decelerations), Leopold’s, vaginal exam, U/S

Reference Point for Describing Fetal Position

- Occiput for cephalic presentation
- Sacrum for breech presentation
- Mentum for face presentation
• **attitude**
  - flexion/extension of fetal head relative to shoulders
  - brow presentation: head partially extended (requires C/S)
  - face presentation: head fully extended
    - mentum posterior always requires C/S, mentum anterior will deliver vaginally

• **station**
  - position of presenting part relative to ischial spines – determined by vaginal exam
    - at ischial spines = station 0 = engaged
    - -5 to -1 cm above ischial spines or
    - +1 to +5 cm below ischial spines
    - alternatively stations can be placed on a scale from -3 to +3

---

**Figure 7. Fetal positions**

**Four Stages of Labor**

**First Stage of Labor**
- latent phase
  - uterine contractions typically infrequent and irregular
  - slow cervical dilatation (usually to 3-4 cm) and effacement
- active phase
  - rapid cervical dilatation to full dilatation (nulliparous ~1.2 cm/h, multiparous ~1.5 cm/h)
  - phase of maximum slope on cervical dilatation curve
  - painful, regular contractions q2-3 min, lasting 45-60 s
  - contractions strongest at fundus, weakest at lower segment

**Second Stage of Labor**
- from full dilatation to delivery of the baby
- mother feels a desire to bear down and push with each contraction
- women may choose a comfortable position that enhances pushing efforts and delivery
  - upright (semi-sitting, squatting) and LLDP are supported in the literature
  - progress measured by descent

**Third Stage of Labor**
- separation and expulsion of the placenta
- can last up to 30 min before intervention indicated
- start oxytocin IV drip, or give 10 U IM or 5 mg IV push after delivery of anterior shoulder in anticipation of placental delivery, otherwise give after delivery of placenta
- routine oxytocin administration in third stage of labor can reduce the risk of PPH by >40%
### Fourth Stage of Labor
- first postpartum hour
- monitor vital signs and bleeding
- repair lacerations
- ensure uterus is contracted (palpate uterus and monitor uterine bleeding)
- inspect placenta for completeness and umbilical cord for presence of 2 arteries and 1 vein
- 3rd and 4th stages of labor most dangerous to the mother (i.e. hemorrhage)

### The Cardinal Movements of the Fetus During Delivery

![Image of fetal movements](image)

**Figure 8. Cardinal movements of fetus during delivery**
Adapted from illustration in *Williams Obstetrics*, 19th ed.

### Analgesic and Anesthetic Techniques in Labor and Birth
- pain or anxiety leads to high endogenous catecholamines, which produce a direct inhibitory effect on uterine contractility

#### Non-Pharmacologic Pain Relief Techniques
- reduction of painful stimuli
  - maternal movement, position change, counter-pressure, abdominal compression
- activation of peripheral sensory receptors
  - superficial heat and cold
  - immersion in water during labor
  - touch and massage, acupuncture, and acupressure
  - TENS
  - intradermal injection of sterile water
  - aromatherapy
- enhancement of descending inhibitory pathways
  - attention focusing and distraction
  - hypnosis
  - music and audio analgesia
  - biofeedback

#### Pharmacologic Methods (see *Anesthesia*, A24)
- nitrous oxide (e.g. self-administered Entonox®)
- narcotics (usually combined with anti-emetic)
- pudendal nerve block
- perineal infiltration with local anesthetic
- regional anesthesia ( epidural block, combined spinal-epidural, spinal)
Fetal Monitoring in Labor

- see online Fetal Heart Rate Tutorial

Vaginal Exam
- membrane status
- cervical effacement (thinning), dilatation, consistency, position, application
- fetal presenting part, position, station
- bony pelvis size and shape
- monitor progress of labor at regular intervals and document in a partogram

Intrapartum Fetal Monitoring
- intermittent fetal auscultation with Doppler device q15-30min for 1 min in first stage active phase following a contraction, q5min during second stage when pushing has begun
- continuous electronic FHR monitoring reserved for abnormal auscultation, prolonged labor, and labor which is induced or augmented, meconium present, multiple gestation/fetal complication
  - routine use of continuous electronic monitoring shown to lead to higher intervention rates and no improvement in outcome for the neonate
  - techniques for continuous monitoring include external (Doppler) vs. internal (fetal scalp electrode) monitoring
- fetal scalp sampling should be used in conjunction with electronic FHR monitoring and contraction monitoring (CTG) to resolve the interpretation of abnormal or atypical patterns

Electronic FHR Monitoring
- FHR measured by Doppler; contractions measured by tocometer
- described in terms of baseline FHR, variability (short-term, long-term), and periodicity (accelerations, decelerations)

- Baseline FHR
  - normal range is 110-160 bpm
  - parameter of fetal well-being vs. distress

- Variability
  - physiologic variability is a normal characteristic of FHR
  - variability is measured over a 15 min period and is described as: absent, minimal (<6 bpm), moderate (6-25 bpm), marked (>25 bpm)
  - normal variability indicates fetal acid-base status is acceptable
  - can only be assessed by electronic fetal monitoring (CTG)
  - variability decreases intermittently even in healthy fetus
- see Table 19, OB34

- Periodicity
  - accelerations: increase of ≥15 bpm lasting ≥15 s, in response to fetal movement or uterine contraction (or ≥10 bpm lasting ≥10 s if <32 wk GA)
  - decelerations: 3 types, described in terms of shape, onset, depth, duration recovery, occurrence, and impact on baseline FHR and variability

Fetal Scalp Blood Sampling
- indicated when atypical or abnormal fetal heart rate is suggested by clinical parameters including heavy meconium or moderately to severely abnormal FHR patterns, including unexplained low variability, repetitive late decelerations, complex variable decelerations, fetal cardiac arrhythmias
- pH ≥7.25: normal, repeat if abnormal FHR persists
- pH 7.21-7.24: repeat assessment in 30 min or consider delivery if rapid fall since last sample
- pH ≤7.20: indicates fetal acidosis, delivery is indicated
• contraindications
  ▪ known or suspected fetal blood dyscrasia (hemophilia, von Willebrand disease)
  ▪ active maternal infection (HIV, genital herpes)

<td>Further assessment required</td>
<td>Action required: review clinical situation, obtain scalp pH, prepare for possible delivery</td>
</tr>
</tbody>
</table>

Adapted from SOGC Guidelines, September 2008

*Previous classification was “reassuring” vs. “non-reassuring”, but distinction is now made between tracings that have some concerning changes but do not require immediate action (atypical) vs. those with major concerns requiring immediate intervention (abnormal)

Fetal Oxygenation

• uterine contractions during labor decrease uteroplacental blood flow, which results in reduced oxygen delivery to the fetus
• most fetuses tolerate this reduction in flow and have no adverse effects
• distribution of oxygen to the fetus depends on maternal, uteroplacental, and fetal factors
• **fetal response to hypoxia/asphyxia**
  - decreased movement, tone, and breathing activities
  - redistribution of fetal blood flow
    - increased flow to brain, heart, and adrenals
    - decreased flow to kidneys, lungs, gut, liver, and peripheral tissues
    - increase in blood pressure
  - transient fetal bradycardia followed by fetal tachycardia
  - anaerobic metabolism (decreased pH)

### Induction of Labor

**Definition**
- artificial initiation of labor before its spontaneous onset for the purpose of delivery of the fetus and placenta

**Prerequisites for Labor Induction**
- capability for C/S if necessary
- maternal
  - short, thin, soft, anterior cervix with open os (“inducible” or “ripe”)
  - if cervix is not ripe, use prostaglandin vaginal insert (Cervidil®), prostaglandin gel (Prepidil®), or Foley catheter
- fetal
  - normal fetal heart tracing
  - cephalic presentation
  - adequate fetal monitoring available
- likelihood of success determined by Bishop score
  - cervix considered unfavorable if <6
  - cervix favorable if ≥6
  - score of 9-13 associated with high likelihood of vaginal delivery

#### Table 22. Bishop Score

</tbody>
</table>

**Indications**
- post-dates pregnancy (generally >41 wk) = most common reason for induction
- maternal factors
  - DM = second most common reason for induction
  - gestational HTN
  - other maternal medical problems, e.g. renal or lung disease
- maternal-fetal factors
  - isoimmunization, PROM, chorioamnionitis, post-term pregnancy

Induction is indicated when the risk of continuing pregnancy exceeds the risks associated with induced labor and delivery.
Induction Methods

CERVICAL RIPENING

Definition
- use of medications or other means to soften, efface, and dilate the cervix to increase likelihood of induction success
- ripening of an unfavorable cervix (Bishop score < 6) is warranted prior to induction of labor

Methods
- intravaginal prostaglandin PGE2 gel (Prostin® gel): long and closed cervix
  - recommended dosing interval of prostaglandin gel is every 6 to 12 h up to 3 doses
- intravaginal PGE2 (Cervidil®): long and closed cervix, may use if ROM
  - continuous release, can be removed if needed
  - controlled release PGE2
- Foley catheter placement to mechanically dilate the cervix

INDUCTION OF LABOR

Amniotomy
- artificial rupture of membranes (amniotomy) to stimulate prostaglandin synthesis and secretion; may try this as initial measure if cervix is dilated
- few studies address the value of amniotomy alone for induction of labor
- amniotomy plus intravenous oxytocin: more women delivered vaginally at 24 h than amniotomy alone (relative risk = 0.03) and had fewer instrumental vaginal deliveries (relative risk = 5.5)

Oxytocin
- oxytocin (Pitocin®): 10 U in 1 L NS, run at 0.5-2 mU/min IV increasing by 1-2 mU/min q20-60min to a max of 36-48 mU/min
  - reduces rate of unsuccessful vaginal deliveries within 24 h when used alone (8.3% vs. 54%, RR 0.16)
  - ideal dosing regime of oxytocin is not known
  - current recommendations: use the minimum dose to achieve active labor and increase q30min as needed
  - reassessment should occur once a dose of 20 mU/min is reached
  - potential complications
    - hyperstimulation/tetanic contraction (may cause fetal distress or rupture of uterus)
    - uterine muscle fatigue, uterine atony (may result in PPH)
    - vasopressin-like action causing anti-diuresis

Augmentation of Labor
- augmentation of labor is used to promote adequate contractions when spontaneous contractions are inadequate and cervical dilatation or descent of fetus fails to occur
- oxytocin (0.5-2 mU/min IV increasing by 1-2 mU/min q20-60min to a max of 36-48 mU/min)
Preterm Labor

Definition
- labor occurring between 20 and 37 wk gestation

Etiology
- idiopathic (most common)
- maternal: infection (recurrent pyelonephritis, untreated bacteriuria, chorioamnionitis), genital infection (bacterial vaginosis is associated with a 2-fold increase in relative risk of preterm birth), HTN, DM, chronic illness, mechanical factors, previous obstetric, gynecological, and abdominal surgeries, socio-environmental (poor nutrition, smoking, drugs, alcohol, stress)
- maternal-fetal: PPROM (common), polyhydramnios, placenta previa, placental abruption, or placental insufficiency
- fetal: multiple gestation, congenital abnormalities of fetus, fetal hydrops
- uterine: incompetent cervix, excessive enlargement (hydramnios), malformations (leiomyomas, septate uterus)

Epidemiology
- preterm labor complicates about 10% of pregnancies

Risk Factors and Prediction of PTL
- maternal risk scoring using above etiologies fails to identify up to 70% of preterm deliveries and is therefore of limited use
- prior history of spontaneous PTL: most important risk factor
- prior history cervical excisions or mechanical dilatation
- cervical length: measured by transvaginal U/S (cervical length >30 mm has high negative predictive value for PTL before 34 wk)
- identification of bacterial vaginosis (Rx metronidazole) and ureaplasma urealyticum (Rx erythromycin) infections: routine screening not supported by current data but it is reasonable to screen high risk women
- fetal fibronectin: a glycoprotein in amniotic fluid and placental tissue functioning to maintain integrity of chorionic-decidual interface in asymptomatic women
  - positive if >50 ng/mL
  - in symptomatic women (i.e. preterm contractions), fetal fibronectin is most effectively combined with U/S detecting cervical length
  - if cervical length is not short and fetal fibronectin is negative, preterm labor is highly unlikely

Clinical Features
- regular contractions (2 in 10 min)
- cervix >2 cm dilated, 80% effaced, or documented change in cervix

Management
A. Initial
- transfer to appropriate facility if stable
- hydration (NS at 150 mL/h)
- bed rest in LLDP
- sedation (morphine)
- avoid repeated pelvic exams (increased infection risk)
- U/S examination of fetus (GA, BPP, position, placenta location, estimated fetal weight)
- prophylactic antibiotics; controversial but may help delay delivery, important to consider if PPROM

B. Suppression of Labor – Tocolysis
- does not inhibit preterm labor completely, but may buy time (used for <48 h) to allow for betamethasone valerate (Celestone®) and/or transfer to appropriate center for care of the premature infant
- requirements (all must be satisfied)
  - preterm labor
  - live, immature fetus, intact membranes, cervical dilatation of <4 cm
  - absence of maternal or fetal contraindications
- contraindications
  - maternal: bleeding (placenta previa or abruption), maternal disease (HTN, DM, heart disease), preeclampsia or eclampsia, chorioamnionitis
  - fetal: erythroblastosis fetalis, severe congenital anomalies, fetal distress/demise, IUGR, multiple gestation (relative)

Positive fetal fibronectin in cervicovaginal fluid (>50 ng/mL) at 24 wk gestation predicted spontaneous PTL at <34 wk with sensitivity of 23%, specificity of 97%, PPV of 25%, NPV of 96%

Tocolytics for Preterm Premature Rupture of Membranes
Cochrane DB Syst Rev 2014;2:CD007062
Purpose: To assess the potential benefits and harms of tocolysis in women with PPROM.
Selection Criteria: Pregnant women with singleton pregnancies and PPROM (23-36 wk and 6 d GA).
Results: 8 studies with 408 women total. Prophylactic tocolysis with PPROM was associated with increased overall latency, without additional benefits for maternal/neonatal outcomes. For women with PPROM before 34 wk, there was a significantly increased risk of chorioamnionitis in women who received tocolysis. Neonatal outcomes were not significantly different.
Conclusion: Although there are limitations to the studies, there is currently insufficient evidence to support tocolytic therapy for women with PPROM, as there was an increase in maternal chorioamnionitis without significant benefits to the infant.
• agents
  - calcium channel blockers: Nifedipine
    - 20 mg PO loading dose followed by 20 mg PO 90 min later
    - 20 mg can be continued q3-8h for 72 h or to a max of 180 mg
    - 10 mg PO q20min x 4 doses
  - prostaglandin synthesis inhibitors: Indomethacin
    - 1st line for early preterm labor (<30 wk GA) or polyhydramnios
    - 50-100 mg PO loading dose followed by 25 mg q4-6h
    - magnesium sulphate was previously used for tocolysis; currently, its primary use in obstetrics is limited to neuroprotection or prevention of eclampsia

C. Enhancement of Fetal Pulmonary Maturity
• betamethasone valerate (Celestone®) 12 mg IM q24h x 2 doses or dexamethasone 6 mg IM q12h x 4 doses
  - 28-34 wk GA: reduces incidence of RDS
  - 24-28 wk GA: reduces severity of RDS, overall mortality, and rate of IVH
  - specific maternal contraindications: active TB

D. Cervical Cerclage
• definition: placement of cervical sutures at the level of the internal os, usually at the end of the first trimester and removed in the third trimester
• indications: cervical incompetence (i.e. cervical dilation and effacement in the absence of increased uterine contractility)
  - emerging evidence indicates that progesterone suppositories are superior to cerclage in preventing preterm labor late in pregnancy
• diagnosis of cervical incompetence
  - obstetrical Hx: silent cervical dilation
  - ability of cervix to hold an inflated Foley catheter during a hysterosonogram
• proven benefit in the prevention of PTL in women with primary structural abnormality of the cervix (e.g. conization of the cervix, connective tissue disorders)

Prognosis
• prematurity is the leading cause of perinatal morbidity and mortality
  - 30 wk or 1,500 g (3.3 lb) = 90% survival
  - 33 wk or 2,000 g (4.4 lb) = 99% survival

Prevention of Preterm Labor
• preventative measures: good prenatal care, identify pregnancies at risk, treat silent vaginal infection or UTI, patient education
  - transvaginal ultrasound of cervical length is recommended only for high-risk pregnancies

## Premature Rupture of Membranes

### Definitions
- PROM or amniorrhexis: rupture of membranes prior to labor at any GA
- prolonged ROM: >24 h elapsed between rupture of membranes and onset of labor
- PPROM: rupture of membranes before 37 wk AND prior to onset of labor

### Risk Factors
- maternal: multiparity, cervical incompetence, infection (cervicitis, vaginitis, STD, UTI), family history of PROM, low socioeconomic class/poor nutrition
- fetal: congenital anomaly, multiple gestation
- other risk factors associated with PTL

### Clinical Features
- history of fluid gush or continued leakage

### Investigations
- sterile speculum exam (avoid introduction of infection)
  - pooling of fluid in the posterior fornix
  - may observe fluid leaking out of cervix on cough/Valsalva ("cascade")
- nitrazine (amniotic fluid turns nitrazine paper blue)
  - low specificity as can be positive with blood, urine, or semen
- ferning (high salt in amniotic fluid evaporates, looks like ferns under microscope)
- U/S to rule out fetal anomalies, assess GA, and BPP

### Membrane Status Determined by
- pooling of fluid on speculum exam
- increased pH of vaginal fluid (nitrazine test)
- ferning of fluid under light microscopy
- decreased AFV on U/S

### L/S Ratio (Lecithin:Sphingomyelin Ratio)
- Lecithin levels increase rapidly after 35 wk gestation, whereas sphingomyelin levels remain relatively constant. The L/S ratio is a measure of fetal lung maturity – less than 2:1 indicates pulmonary immaturity. Presence of blood or meconium in the amniotic fluid can affect the ratio
Management
- admit for expectant management and monitor vitals q4h, daily BPP and WBC count
- avoid introducing infection with examinations (do NOT do a bimanual exam)
- cultures (cervix for GC, lower vagina for GBS)
- assess fetal lung maturity by L/S ratio of amniotic fluid
  - consider administration of betamethasone valerate (Celestone®) to accelerate maturity if <32 wk and no evidence of infection
  - consider tocolysis for 48 h to permit administration of steroids if PPROM induces labor
- if not in labor or labor not indicated, consider antibiotics (controversial)
  - studies show broad spectrum coverage increases the time to onset of labor from PROM by 5-7 d with no increase in maternal or neonatal morbidity or mortality
- deliver urgently if evidence of fetal distress and/or chorioamnionitis

Table 23. PROM Management

</tr>
</tbody>
</table>

Prognosis
- varies with gestational age
- 90% of women with PROM at 28-34 wk GA go into spontaneous labor within 1 wk
- 50% of women with PROM at <26 wk GA go into spontaneous labor within 1 wk
- complications: cord prolapse, intrauterine infection (chorioamnionitis), premature delivery, limb contracture

Breech Presentation

Definition
- fetal buttocks or lower extremity is the presenting part as determined on U/S
- complete (10%): flexion at hips and knees
- frank (60%): flexion at hips, extension at knees
  - most common type of breech presentation
  - most common breech presentation to be delivered vaginally
- footling (30%): may be single or double with extension at hip(s) and knee(s) so that foot is the presenting part

Epidemiology
- occurs in 3-4% of pregnancies at term (25% before 28 wk)

Risk Factors
- maternal: pelvis (contracted), uterus (shape abnormalities, intrauterine tumors, fibroids), extrauterine tumors causing compression, grand multiparity
- maternal-fetal: placenta (previa), amniotic fluid (poly-/oligohydramnios)
- fetal: prematurity, multiple gestation, congenital malformations (found in 6% of breeches; 2-3% if in vertex presentations), abnormalities in fetal tone and movement, aneuploidy

Management
- ECV: repositioning of fetus within uterus under U/S guidance
  - overall success rate of 65%
  - criteria: singleton, unengaged presenting part, reactive NST
  - contraindications: previous T3 bleed, prior classical C/S, previous myomectomy, oligohydramnios, PROM, placenta previa, abnormal U/S, suspected IUGR, HTN, uteroplacental insufficiency, nuchal cord
  - risks: abruption, cord compression
  - method: tocometry, followed by ultrasound guided transabdominal manipulation of fetus with consistent fetal heart monitoring
  - if patient Rh negative, give Rhogam® prior to procedure
  - good prognostic factors (for a successful version)
    - multiparous, good fluid volume, small baby, skilled obstetrician
  - pre- or early labor ultrasound to assess type of breech presentation, fetal growth, estimated weight, attitude of fetal head; if ultrasound unavailable, recommend C/S
  - trial of labor and elective C/S should be presented as options with the risks and benefits outlined; obtain informed consent
method for vaginal breech delivery
  - encourage effective maternal pushing efforts
  - at delivery of after-coming head, assistant must apply suprapubic pressure to flex and engage fetal head
  - delivery can be spontaneous or assisted; avoid fetal traction
  - apply fetal manipulation only after spontaneous delivery to level of umbilicus
- C/S recommended if: the breech has not descended to the perineum in the second stage of labor after 2 h, in the absence of active pushing, or if vaginal delivery is not imminent after 1 h of active pushing
- contraindications to vaginal breech delivery
  - cord presentation
  - clinically inadequate maternal pelvis
  - fetal factors incompatible with vaginal delivery

Prognosis
- regardless of route of delivery, breech infants have lower birth weights and higher rates of perinatal mortality, congenital anomalies, abruption, and cord prolapse

Vaginal Birth After Cesarean (Trial of Labor After Cesarean)
- recommended after previous low transverse incision
- success rate varies with indication for previous C/S (generally 60-80%)
- risk of uterine rupture (<1% with low transverse incision)

Contraindications
- previous classical, inverted T, or unknown uterine incision, or complete transection of uterus (6% risk of rupture)
- history of hysterotomy or previous uterine rupture
- multiple gestation
- non-vertex presentation or placenta previa
- inadequate facilities or personnel for emergency C/S

Prolonged Pregnancy
Definition
- pregnancy beyond 42 wk GA

Epidemiology
- 41 wk GA: up to 27%
- 42 wk GA: 4-14%

Etiology
- most cases idiopathic
- anencephalic fetus with no pituitary gland
- placental sulfatase deficiency (X-linked recessive condition in 1/2,000-1/6,000 infants) – rare

Clinical Features
- postmaturity syndrome: 10-20% of post-term pregnancies (fetal weight loss, reduction in subcutaneous fat, scaling, dry skin from placental insufficiency, long thin body, open-eyed, alert and worried look, long nails, palms and soles wrinkled)
- with increasing GA, higher rates of: intrauterine infection, asphyxia, meconium aspiration syndrome, placental insufficiency, placental aging and infarction, macrosomia, dystocia, fetal distress, operative deliveries

Management
- GA 40-41 wk: expectant management
  - no evidence to support IOL or C/S unless other risk factors for morbidity are present (see prognosis)
- GA ≥41 wk: offer IOL if vaginal delivery is not contraindicated
  - IOL shown to decrease C/S, fetal heart rate changes, meconium staining, macrosomia, and death when compared with expectant management
- GA ≥41 wk and expectant management elected: serial fetal surveillance
  - fetal movement count by the mother
  - BPP q3-4d
  - If AFI is decreased, labor will be induced
Prognosis
- if >42 wk, perinatal mortality 2-3x higher (due to progressive uteroplacental insufficiency)
- morbidity increased with HTN in pregnancy, DM, abruption, IUGR, and multiple gestation

Intrauterine Fetal Death

Definition
- fetal death in utero after 20 wk GA

Epidemiology
- 1% of pregnancies

Etiology
- 50% idiopathic
- 50% secondary to HTN, DM, erythroblastosis fetalis, congenital anomalies, umbilical cord or placental complications, intrauterine infection, APS

Clinical Features
- decreased perception of fetal movement by mother
- SFH and maternal weight not increasing
- absent fetal heart tones (not diagnostic)
- high MSAFP

Management
- diagnosis: absent cardiac activity and fetal movement on U/S required for diagnosis
- determine secondary cause
  - maternal: HbA1c, Kleihauer-Betke, VDRL, ANA, antibody screens, INR/PTT, serum/urine toxicology screens, cervical and vaginal cultures, TORCH screen
  - fetal: chromosomes, cord blood, skin biopsy, genetics evaluation, autopsy
  - placenta: pathology, bacterial cultures

Treatment
- induction of labor
- monitor for maternal coagulopathy (10% risk of DIC)
- parental psychological care as per hospital protocol
- comprehensive discussion within 3 mo about final investigation and post-mortem results, help make plans for future pregnancies

Complications of Labor and Delivery

Meconium in Amniotic Fluid

Epidemiology
- present early in labor in 10% of pregnancies
- in general, meconium may be present in up to 25% of all labors; usually NOT associated with poor outcome, but extra care is required at time of delivery to avoid aspiration

Etiology
- likely cord compression ± uterine hypertonus
- may indicate undiagnosed breech
- increasing meconium during labor may be a sign of fetal distress

Features
- consistency and color
  - light yellow/green or dark green-black in color
  - may be watery or thicker

Treatment
- call respiratory therapy, neonatology, or pediatrics to delivery room
- oropharynx suctioning upon head expulsion or immediately after delivery if baby not breathing spontaneously (do NOT stimulate infant before)
- consider amnioinfusion of ~800 mL of IV NS over 50-80 min during active stage of labor and a maintenance dose of ~3 mL/min until delivery
- closely monitor FHR for signs of fetal distress
Abnormal Progression of Labor (Dystocia)

**Definition**
- Expected patterns of descent of the presenting part and cervical dilatation fail to occur in the appropriate time frame; can occur in all stages of labor
- During active phase: >4 h of <0.5 cm/h
- During 2nd phase: >1 h with no descent during active pushing

**Etiology**
- **Power** (leading cause): contractions (hypotonic, incoordinate), inadequate maternal expulsive efforts
- **Passenger**: fetal position, attitude, size, anomalies (hydrocephalus)
- **Passage**: pelvic structure (CPD), maternal soft tissue factors (tumors, full bladder or rectum, vaginal septum)
- **Psyche**: hormones released in response to stress may contribute to dystocia; psychological and physiological stress should be evaluated as part of the management once dystocia has been diagnosed

**Management**
- Confirm diagnosis of labor (rule out false labor)
- Search for factors of CPD
- Diagnosed if adequate contractions measured by intrauterine pressure catheter (IUPC) with no descent/dilatation for >2 h
- Management: if CPD ruled out, IV oxytocin augmentation ± amniotomy

**Risks of Dystocia**
- Inadequate progression of labor is associated with an increased incidence of:
  - Maternal stress
  - Maternal infection
  - Postpartum hemorrhage
  - Need for neonatal resuscitation

Shoulder Dystocia

**Definition**
- Impaction of anterior shoulder of fetus against symphysis pubis after fetal head has been delivered
- Life threatening emergency

**Etiology/Epidemiology**
- Incidence 0.15-1.4% of deliveries
- Occurs when breadth of shoulders is greater than biparietal diameter of the head

**Risk Factors**
- Maternal: Obesity, DM, multiparity
- Fetal: Prolonged gestation, macrosomia
- Labor
  - Prolonged 2nd stage
  - Instrumental midpelvic delivery

**Clinical Features**
- "Turtle sign": head delivered but retracts against inferior portion of pubic symphysis
- Complications
  - Chest compression by vagina or cord compression by pelvis can lead to hypoxia
  - Brachial plexus injury (Erb's palsy: C5-C7; Klumpke's palsy: C8-T1)
    - 90% resolve within 6 mo
  - Fetal fracture (clavicle, humerus, cervical spine)
  - Maternal perineal injury; may result in PPH

**Treatment**
- Goal: to displace anterior shoulder from behind symphysis pubis; follow a stepwise approach of maneuvers until goal achieved
- Other options
  - Cleidotomy (deliberate fracture of neonatal clavicle)
  - Zavanelli maneuver: replacement of fetus into uterine cavity and emergent C/S
  - Symphysiotomy

**Prognosis**
- 1% risk of long-term disability for infant
Umbilical Cord Prolapse

Definition
• descent of the cord to a level adjacent to or below the presenting part, causing cord compression between presenting part and pelvis

Etiology/Epidemiology
• increased incidence with prematurity/PROM, fetal malpresentation (~50% of cases), low-lying placenta, polyhydramnios, multiple gestation, CPD
• incidence: 0.17-0.63%

Clinical Features
• visible or palpable cord
• FHR changes (variable decelerations, bradycardia, or both)

Treatment
• emergency C/S
• O2 to mother, monitor fetal heart
• alleviate pressure of the presenting part on the cord by placing digit in vagina (maintain this position until C/S)
• keep cord warm and moist by replacing it into the vagina ± applying warm saline soaks
• position mother in Trendelenburg or knee-to-chest position
• if fetal demise or too premature (<22 wk), allow labor and delivery

Uterine Rupture

Etiology/Epidemiology
• associated with previous uterine scar (in 40% of cases), hyperstimulation with oxytocin, grand multiparity, and previous intrauterine manipulation
• generally occurs during labor, but can occur earlier with a classical incision
• 0.5-0.8% incidence, up to 12% with classical incision

Clinical Features
• prolonged fetal bradycardia – most common presentation
• acute onset abdominal pain
• hyper or hypotonic uterine contractions
• vaginal bleed

Risk Factors
• uterine scarring (i.e. previous uterine surgeries including Cesarean, perforation with D&C)
• excessive uterine stimulation (i.e. protracted labor, oxytocin)
• uterine trauma (i.e. operative equipment, ECV)
• multiparity
• uterine abnormalities

Treatment
• rule out placental abruption
• immediate delivery for fetal survival
• maternal stabilization (may require hysterectomy)

Complications
• maternal mortality 1-10%
• maternal hemorrhage, shock, DIC
• amniotic fluid embolus
• hysterectomy if uncontrollable hemorrhage
• fetal distress, associated with 50% fetal mortality

Approach to the Management of Shoulder Dystocia
ALARMER
• Apply suprapubic pressure and ask for help
• Legs in full flexion (McRobert’s maneuver)
• Anterior shoulder disimpaction (suprapubic pressure)
• Release posterior shoulder by rotating it anteriorly with hand in the vagina under adequate anesthesia
• Manual corkscrew i.e. rotate the fetus by the posterior shoulder until the anterior shoulder emerges from behind the maternal symphysis
• Episiotomy
• Rollover (on hands and knees)

*Note that suprapubic pressure and McRobert’s maneuver together will resolve 90% of cases

Umbilical Cord Accident Causes
• Nuchal cord
  - Type A (looped)
  - Type B (hitched)
• Body loop
• Single artery
• True knot
• Torsion
• Velamentous
• Short cord <35 cm
• Long cord >80 cm

Maternal Mortality Causes
• Thromboembolism
• Cardiac event
• Suicide
• Sepsis
• Ectopic pregnancy
• HTN
• Amniotic fluid embolism
• Hemorrhage
**Amniotic Fluid Embolus**

**Definition**
- amniotic fluid debris in maternal circulation triggering an anaphylactoid immunologic response

**Etiology/Epidemiology**
- rare intrapartum or immediate postpartum complication
- 60-80% maternal mortality rate, accounts for 10% of all maternal deaths
- leading cause of maternal death in induced abortions and miscarriages
- 1/8,000-1/80,000 births

**Risk Factors**
- placental abruption
- rapid labor
- multiparity
- uterine rupture
- uterine manipulation

**Differential Diagnosis**
- pulmonary embolus, drug-induced anaphylaxis, septic shock, eclampsia, HELLP syndrome, abruption, chronic coagulopathy

**Clinical Features**
- sudden onset of respiratory distress, cardiovascular collapse (hypotension, hypoxia), and coagulopathy
- seizure in 10%
- ARDS and left ventricular dysfunction seen in survivors

**Management**
- supportive measures (high flow O₂, ventilation support, fluid resuscitation, inotropic support, ± intubation), coagulopathy correction
- ICU admission

---

**Chorioamnionitis**

**Definition**
- infection of the chorion, amnion, and amniotic fluid typically due to ascending infection by organisms of normal vaginal flora

**Etiology/Epidemiology**
- incidence 1-5% of term pregnancies and up to 25% in preterm deliveries
- ascending from vagina
- predominant microorganisms include: GBS, Bacteroides and Prevotella species, E. coli, and anaerobic Streptococcus

**Risk Factors**
- prolonged ROM, long labor, multiple vaginal exams during labor, internal monitoring
- bacterial vaginosis and other vaginal infections

**Clinical Features**
- maternal fever, maternal or fetal tachycardia, uterine tenderness, foul and purulent cervical discharge

**Investigations**
- CBC: leukocytosis
- amniotic fluid: leukocytes or bacteria

**Treatment**
- IV antibiotics
  - ampicillin (2 g IV q6h) and gentamicin (1.5 mg/kg q8h)
  - anaerobic coverage (i.e. clindamycin if C/S)
- expedient delivery regardless of gestational age

**Complications**
- bacteremia of mother or fetus, wound infection if C/S, pelvic abscess, infant meningitis
Operative Obstetrics

Operative Vaginal Delivery

Definition
- forceps or vacuum extraction

Indications
- fetal
  - atypical or abnormal fetal heart rate tracing
  - consider if second stage is prolonged as this may be due to poor contractions or failure of fetal head to rotate
- maternal
  - need to avoid voluntary expulsive effort (e.g. cardiac/cerebrovascular disease)
  - exhaustion, lack of cooperation, and excessive analgesia may impair pushing effort

Forceps

Outlet Forceps Position
- head visible between labia in between contractions
- sagittal suture in or close to AP diameter
- rotation cannot exceed 45°

Low Forceps Position
- presenting part at station +2 or greater
- subdivided based on whether rotation less than or greater than 45 degrees

Mid Forceps Position
- presenting part below spines but above station +2
- rarely done

Types of Forceps
- Simpson or Tucker-McLane forceps for OA presentations
- Kielland (rotational) forceps when rotation of head required
- Piper forceps for breech

Vacuum Extraction

- traction instrument used as alternative to forceps delivery; aids maternal pushing

Table 24. Advantages and Disadvantages of Forceps vs. Vacuum Extraction

<table>

</tbody>
</table>

Lacerations

- first degree: involves skin and vaginal mucosa but not underlying fascia and muscle
- second degree: involves fascia and muscles of the perineal body but not the anal sphincter
- third degree: involves the anal sphincter but does not extend through it
- fourth degree: extends through the anal sphincter into the rectal mucosa
Episiotomy

**Definition**
- incision in the perineal body at the time of delivery
- essentially a controlled second degree laceration
- midline: incision through central tendinous portion of perineal body and insertions of superficial transverse perineal and bulbocavernousus muscle
  - better healing but increased risk of deep tear
- mediolateral: incision through bulbocavernosus, superficial transverse perineal muscle, and levator ani
  - reduced risk of extensive tear but poorer healing and more pain
  - easier to repair

**Indications**
- to relieve obstruction of the unyielding perineum
- instrumental delivery
- controversial between practitioners as to whether it is preferable to make a cut or let the perineum tear as needed
- current evidence suggests letting perineum tear and then repair as needed (restricted use)

**Complications**
- infection, hematoma, extension into anal musculature, or rectal mucosa, fistula formation, incontinence

Cesarean Delivery

**Epidemiology**
- incidence 20-25%

**Indications**
- maternal: obstruction, active herpetic lesion on vulva, invasive cervical cancer, previous uterine surgery, underlying maternal illness (eclampsia, HELLP syndrome, heart disease)
- maternal-fetal: failure to progress, placental abruption or previa, vasa previa
- fetal: abnormal fetal heart tracing, malpresentation, cord prolapse, certain congenital anomalies

**Types of Cesarean Incisions**
- skin
  - transverse (i.e. Pfannenstiel)
    - decreased exposure and slower entry
    - improved strength and cosmesis
  - vertical midline
    - rapid peritoneal entry and increased exposure
    - increased dehiscence
  - uterine
    - low transverse (most common): in noncontractile segment
      - decreased chance for rupture in subsequent pregnancies
    - low vertical
      - used for very preterm infants, poorly developed maternal lower uterine segment
      - classical (rare): in thick, contractile segment
      - used for transverse lie, fetal anomaly, >2 fetuses, lower segment adhesions, obstructing fibroid, morbidly obese patients

**Risks/Complications**
- anesthesia
- hemorrhage (average blood loss ~1,000 cc)
- infection (UTI, wound, endometritis)
- single dose prophylactic antibiotic should be used (e.g. cefazolin 1-2 g)
- injury to surrounding structures (bowel, bladder, ureter, uterus)
- thromboembolism
- increased recovery time/hospital stay
- maternal mortality (<0.1%)
Puerperal Complications

- puerperium: 6 wk period of adjustment after pregnancy when pregnancy-induced anatomic and physiologic changes are reversed

Postpartum Hemorrhage

Definition
- loss of >500 mL of blood at the time of vaginal delivery, or >1,000 mL with C/S
- early – within first 24 h postpartum
- late – after 24 h but within first 6 wk

Epidemiology
- incidence 5-15%

Etiology (4 Ts)
1. Tone
   - uterine atony
     - most common cause of PPH
     - avoid by giving oxytocin with delivery of the anterior shoulder or placenta
     - occurs within first 24 h
   - due to
     - labor (prolonged, precipitous, induced, augmented)
     - uterus (infection, over-distention)
     - placenta (abruption, previa)
     - maternal factors (grand multiparity, gestational HTN)
     - halothane anesthesia

2. Tissue
   - retained placental products
   - retained blood clots in an atonic uterus
   - gestational trophoblastic neoplasia

3. Trauma
   - laceration (vagina, cervix, uterus), episiotomy, hematoma (vaginal, vulvar, retroperitoneal), uterine rupture, uterine inversion

4. Thrombin
   - coagulopathy
     - most identified prior to delivery (low platelets increases risk)
     - includes hemophilia, DIC, Aspirin® use, ITP, TTP, vWD (most common)
     - therapeutic anti-coagulation

Investigations
- assess degree of blood loss and shock by clinical exam
- explore uterus and lower genital tract for evidence of tone, tissue, or trauma
- may be helpful to observe red-topped tube of blood – no clot in 7-10 min indicates coagulation problem

Management
- ABCs
- 2 large bore IVs and crystalloids
- CBC, coagulation profile, cross and type 4 units pRBCs
- treat underlying cause

Medical Therapy
- oxytocin 20 U/L NS or RL IV continuous infusion
  - in addition can give 10 U IMM after delivery of the placenta
- methylergonavine maleate (ergotamine) 0.25 mg IM/IMM q5min up to 1.25 mg; can be given as IV bolus of 0.125 mg (may exacerbate HTN)
- carbofrost (Hemabate®), a synthetic PGF-1α analog 0.25 mg IM/IMM q15min to max 2 mg (major prostaglandin side effects and contraindicated in cardiovascular, pulmonary, renal, and hepatic dysfunction)
- misoprostol 600 µg-1 g (side effect: pyrexia)
- tranexamic acid (Cyklokapron®) 1 g IV, an antifibrinolytic
Local Control
- bimanual compression: elevate the uterus and massage through patient's abdomen
- uterine packing (mesh with antibiotic treatment)
- Bakri Balloon for tamponade: may slow hemorrhage enough to allow time for correction of coagulopathy or for preparation of an OR

Surgical Therapy (Intractable PPH)
- D&C (beware of vigorous scraping which can lead to Asherman's syndrome)
- embolization of uterine artery or internal iliac artery by interventional radiologist
- laparotomy with bilateral ligation of uterine artery (may be effective), internal iliac artery (not proven), ovarian artery, or hypogastric artery
- hysterectomy last option with angiographic embolization if post-hysterectomy bleeding

Retained Placenta

Definition
- placenta undelivered after 30 min postpartum

Etiology
- placenta separated but not delivered
- abnormal placental implantation (placenta accreta, placenta increta, placenta percreta)

Risk Factors
- placenta previa, prior C/S, post-pregnancy curettage, prior manual placental removal, uterine infection

Clinical Features
- incomplete placenta removed
- risk of postpartum hemorrhage and infection

Investigations
- explore uterus
- assess degree of blood loss

Management
- 2 large bore IVs, type and screen
- Brant maneuver (firm traction on umbilical cord with one hand applying suprapubic pressure to avoid uterine inversion by holding uterus in place)
- oxytocin 10 IU in 20 mL NS into umbilical vein
- manual removal if above fails
- D&C if required

Uterine Inversion

Definition
- inversion of the uterus through cervix ± vaginal introitus

Etiology/Epidemiology
- often iatrogenic (excess cord traction with fundal placenta)
- excessive use of uterine tocolytics
- more common in grand multiparous (lax uterine ligaments)
- 1/1,500-1/2,000 deliveries

Clinical Features
- can cause profound vasovagal response with vasodilation and hypovolemic shock
- shock may be disproportionate to maternal blood loss

Management
- urgent management essential, call anesthesia
- ABCs: initiate IV crystalloids
- can use tocolytic drug (see Management of Preterm Labor, OB37) or nitroglycerin IV to relax uterus and aid replacement
- replace uterus without removing placenta
- remove placenta manually and withdraw slowly
- IV oxytocin infusion (only after uterus replaced)
- re-explore uterus
- may require general anesthetic ± laparotomy
Postpartum Pyrexia

Definition
• fever >100.4°F on any 2 of the first 10 d postpartum, except the first day

Etiology
• endometritis
• wound infection secondary to C/S
• mastitis/engorgement
• UTI
• atelectasis
• pneumonia

Investigations
• detailed history and physical exam, relevant cultures
• for endometritis: blood and genital cultures

Treatment
• depends on etiology
  ▪ infection: empiric antibiotics, adjust when sensitivities available
  ▪ endometritis: clindamycin + gentamycin IV
  ▪ mastitis: cloxacillin or cephalaxin
  ▪ wound infection: cephalaxin
  ▪ DVT: anticoagulants
  ▪ prophylaxis against post-C/S endometritis: begin antibiotic immediately after cord clamping and administer only 1-3 doses – cefazolin is most common choice

ENDOMETRITIS
• definition: infection of uterine myometrium and parametrium
• clinical features: fever, chills, abdominal pain, uterine tenderness, foul-smelling discharge, or lochia
• treatment: depends on infection severity; oral antibiotics if well, IV with hospitalization in moderate to severe cases

VENOUS THROMBOEMBOLISM
• see Venous Thromboembolism, OB20

Mastitis
• definition: inflammation of mammary glands
• must rule out inflammatory carcinoma, as indicated
• differentiate from mammary duct ectasia: mammary duct(s) beneath nipple clogged and dilated ± ductal inflammation ± nipple discharge (thick, gray to green), often postmenopausal women

| Table 25. Lactational vs. Non-Lactational Mastitis |
|-----------------------------------|-------------------------------------------------|
| **Lactational** | **Non-Lactational** |
| Epidemiology | Peniductal mastitis most common |
| Often 2-3 wk postpartum | Mean age 32 yr |
| Etiology | May be sterile |
| S. aureus | May be infected with S. aureus or other anaerobes |
| | Smoking is risk factor |
| | May be associated with mammary duct ectasia |
| Symptoms | Nipple inversion |
| Unilateral localized pain | Subareolar pain |
| Tenderness | May have subareolar mass |
| Erythema | Discharge (variable color) |
| Treatment | Broad-spectrum antibiotics and I&O |
| Heat or ice packs | Total duct excision (definitive) |
| Continued nursing/pumping | Antibiotics (dicloxacillin/cephalexin) |
| | (Erythromycin if pen-allergic) |
| Abscess | If mass does not resolve, FNA to exclude cancer and U/S to assess presence of abscess |
| Fluctuant mass | Treatment includes antibiotics, aspiration, or I&O (tends to recur) |
| Purulent nipple discharge | May develop mammary duct fistula |
| Fever, leukocytosis | A minority of non-lactational abscesses may occur peripherally in breast with no associated periductal mastitis (usually S. aureus) |
| Discontinue nursing, IV antibiotics (nafcillin/oxacillin), I&O usually required | |
**Postpartum Mood Alterations**

**POSTPARTUM BLUES**
- 85% of new mothers, onset day 3–10; extension of the “normal” hormonal changes and adjustment to a new baby
- self-limited, should resolve by 2 wk
- manifested by mood lability, depressed affect, increased sensitivity to criticism, tearfulness, fatigue, irritability, poor concentration/despondency

**POSTPARTUM DEPRESSION**
- definition: major depression occurring in a woman within 6 mo of childbirth
- epidemiology: 10–20%, risk of recurrence 50%
- risk factors
  - personal or family history of depression (including PPD)
  - prenatal depression or anxiety
  - stressful life situation
  - poor support system
  - unwanted pregnancy
  - colicky or sick infant
- clinical features: suspect if the “blues” last beyond 2 wk, or if the symptoms in the first two weeks are severe (e.g. extreme disinterest in the baby, suicidal or homicidal/infanticidal ideation)
- assessment: Edinburgh Postnatal Depression Scale or other
- treatment: antidepressants, psychotherapy, supportive care, ECT if refractory
- prognosis: interferes with bonding and attachment between mother and baby so it can have long-term effects

**POSTPARTUM PSYCHOSIS**
- definition: onset of psychotic symptoms over 24-72 h within first month postpartum, can present in the context of depression
- epidemiology: rare (0.2%)

**Postpartum Care**

Postpartum Office Visit at 6 Weeks

**Care of Mother (The 10 Bs)**
- Be careful: do not use douches or tampons for 4-6 wk post-delivery
- Be fit: encourage gradual increases in walking. Kegel exercises
- Birth control: assess for use of contraceptives; breastfeeding is NOT an effective method of birth control (see Gynecology, GY16, for more detail about different contraceptive options postpartum)
- Bladder: assess for urinary incontinence, maintain high fluid intake
- Bleeding: (see Lacerations, OB45), 300 µg of RhIG should be given if Rh+ fetus and Rh– mother or extensive bleeding at delivery
- Blood pressure: especially if gestational HTN
- Blood tests: glucose, CBC (for anemia as sign of hematomas, retained placenta)
- Blues: (see Postpartum Mood Alterations)
- Bowel: fluids and high-fiber foods, bulk laxatives; for hemorrhoids/perineal tenderness: pain meds, doughnut cushion, Sitz baths, ice compresses
- Breast and pelvic exam: watch for Staphylococcal or Streptococcal mastitis/abscess, ± Pap smear at 6 wk

**Physiological Changes Postpartum**
- uterus weight rapidly diminishes through catabolism, cervix loses its elasticity and regains firmness
  - should involute ~1 cm below umbilicus per day in first 4-5 d, reaches non-pregnant state in 4-6 wk postpartum
- ovulation resumes in ~45 d for non-lactating women and within 3-6 mo for lactating women
- lochia: normal vaginal discharge postpartum
  - decreases and changes in color from red (lochia rubra; presence of erythrocytes) → yellow (lochia serosa) → white (lochia alba; residual leukorrhea) over 3-6 wk
  - foul-smelling lochia suggests endometritis

The acronym “BUBBLES” for what to ask about when rounding on postpartum care. Modify this for C/S or vaginal delivery.
- Baby care and breastfeeding (latch, amount)
- Uterus – firm or boggy?
- Bladder function – Voiding well? Dysuria?
- Bowel function – Passing gas or stool? Constipated?
- Lochia or discharge – Any blood?
- Episiotomy/laceration/incision – Pain controlled?
- Symptoms of VTE – Dyspnea? Calf pain?
Breastfeeding Problems
- inadequate milk: consider domperidone
- breast engorgement: cool compress, manual expression/pumping
- nipple pain: clean milk off nipple after feeds, moisture cream, topical steroid if needed
- mastitis: treat promptly (see Postpartum Pyrexia, OB49)
- inverted nipples: makes feeding difficult
- maternal medications: may require pediatric consultation (see Breastfeeding and Drugs)

Bladder Dysfunction
- pelvic floor prolapse can occur after vaginal delivery
- stress or urge urinary incontinence common
- increased risk with instrumental delivery or prolonged second stage
- conservative management: pelvic floor retraining with Kegel exercises, vaginal cones, or pessaries, lifestyle modifications (e.g. limit fluid, caffeine intake)
- surgical management: minimally invasive procedures (tension-free vaginal tape, transobturator tape, midurethral sling)

Puerperal Pain
- “after pains” common in first 3 d due to uterine contractions; encourage simple analgesia
- ice packs can be used on perineum if painful
- encourage regular analgesia and stool softener

Breastfeeding and Drugs

Table 26. Drug Safety During Breastfeeding

<tr>
<td>Rh IgG (Rhogam&lt;sup&gt;®&lt;/sup&gt;)</td>
<td>300 µg IM x 1 dose</td>
<td>Given to Rh negative women</td>
</tr>
</tbody>
</table>

- Routinely at 28 wk GA
- Within 72 h of birth of Rh +ve fetus
- Positive Kleihauer-Betke test
- With any invasive procedure in pregnancy
- Ectopic pregnancy
- Antepartum hemorrhage
- Miscarriage or therapeutic abortion (dose: 50 µg IM only)

**Common Discharge Medications**

- Oxycodone IR 5-10 mg PO q4-6h PRN
- Docusate sodium 100 mg PO bid

Misoprostol (Cystotec<sup>®</sup>) is also indicated to protect against NSAID-induced gastric ulcers in non-pregnant individuals. The use of misoprostol for cytoprotection is contraindicated in pregnancy; warn female patients of this contraindication.

Basic Anatomy Review

Figure 1. Anatomy of the eye

Figure 2. Layers of the retina
Differential Diagnoses of Common Presentations

Loss of Vision

Transient (seconds to hours)
- Transient ischemic attack (TIA)
- Migraine with aura
- Cornea/Anterior Segment
  - Corneal edema
  - Hyphema
  - Acute angle-closure glaucoma
  - Trauma/foreign body
- Vitreous/Retina/Optic Nerve
  - Vitreous hemorrhage
  - RD
  - Retinal artery/vein occlusion
  - Acute macular lesion
  - Optic neuritis
  - Temporal arteritis
  - Anterior ischemic optic neuropathy (AION)
- Cortical/Other
  - Occipital infarction/hemorrhage
  - Cortical blindness
  - Functional (non-organic, diagnosis of exclusion)

Acute (seconds to days)

Chronic (weeks to months)

Cornea/Anterior Segment
- Corneal dystrophy/scarring/edema
- Refractive error
- Cataract
- Glaucoma

Vitreous/Retina/Optic Nerve
- AMD
- DR
- Retinal vascular insufficiency
- Compressive optic neuropathy (intracranial mass, orbital mass)
- Intraocular neoplasm
- Retinoblastoma

Cortical/Other
- Pituitary adenoma
- Medication-induced (sildenafil, amiodarone)
- Nutritional deficiency
- Papilledema

Note: Anti-VEGF treatment for exudative AMD and diabetic macular edema may reverse some vision loss

Top 3 Differential Diagnosis of Acute Loss of Vision
- Trauma/foreign body
- Retinal artery/vein occlusion
- RD

Top 3 Differential Diagnosis of Chronic Loss of Vision
Reversible
- Cataract
- Refractive error
- Corneal dystrophy

Irreversible
- AMD
- Glaucoma
- DR

Figure 3. Tear drainage from the eye (lacrimal apparatus)

Figure 4. Loss of vision
**Red Eye**

- lids/orbit/lacrimal system
  - hordeolum/chalazion
  - blepharitis
  - entropion/ectropion
  - foreign body/laceration
  - dacrocystitis/dacryoadenitis

- conjunctiva/sclera
  - subconjunctival hemorrhage
  - conjunctivitis
  - dry eyes
  - pterygium
  - episcleritis/scleritis
  - preseptal/orbital cellulitis

- cornea
  - foreign body (including contact lens)
  - keratitis
  - abrasion, laceration
  - ulcer

- anterior chamber
  - anterior uveitis (iritis, iridocyclitis)
  - acute angle-closure glaucoma
  - hyphema (blood in anterior chamber)
  - hypopyon (pus in anterior chamber)

Other
- trauma
- post-operative
- endophthalmitis

**Ocular Pain**

- differentiate from eye fatigue (asthenopia)
- herpes zoster prodrome
- trauma/foreign body
- keratitis
- corneal abrasion, corneal ulcer
- acute angle-closure glaucoma
- acute uveitis
- scleritis, episcleritis
- optic neuritis

**Floaters**

- age-related vitreous syneresis (shrinkage and collapse of vitreous gel)
- PVD
- vitreous hemorrhage
- retinal tear/detachment
- posterior uveitis

**Flashes of Light (Photopsia)**

- PVD
- retinal tear/detachment
- migrane with aura

**Photophobia (Severe Light Sensitivity)**

- corneal abrasion, corneal ulcer
- keratitis
- acute angle-closure glaucoma
- iritis
- meningitis, encephalitis
- migraine
- subarachnoid hemorrhage (SAH)

**Diplopia (Double Vision)**

- binocular diplopia (occurs with both eyes open, eliminated with occlusion of either eye)
  - strabismus, CN palsy (III, IV, VI) secondary to ischemia, DM, tumor, trauma, myasthenia gravis, muscle restriction/entrapment, thyroid ophthalmopathy, INO secondary to multiple sclerosis, brainstem infarct
- monocular diplopia (occurs with one eye open, remains with occlusion of unaffected eye)
  - refractive error, strands of mucus in tear film, keratoconus, cataracts, dislocated lens, peripheral iridotomy

**Ocular Problems in the Elderly**

- blepharitis
- ptosis
- entropion, ectropion
- dry eyes, epiphora (excessive tearing)
- presbyopia
- cataracts
- glaucoma
- AMD
- retinal artery/vein occlusion
- temporal arteritis (arteritic ischemic optic neuropathy)

**Ocular Problems in the Contact Lens Wearer**

- SPK from dry eyes
- solution hypersensitivity
- tight lens syndrome
- corneal abrasion
- giant papillary conjunctivitis/contact lens allergy
- sterile corneal infiltrates (immunologic)
- infected ulcers (*Pseudomonas, Acanthamoeba*)

**Acute Painless Vision Loss**

- vitreous hemorrhage
- retinal artery/vein occlusion
- RD
- AION
- optic neuritis
- amaurosis fugax

### Ocular Emergencies

These require urgent consultation to an ophthalmologist for management

**Sight Threatening**
- lid/globe lacerations
- chemical burn
- corneal ulcer
- gonococcal conjunctivitis
- acute iritis
- acute angle-closure glaucoma
- CRAO
- intraocular foreign body
- RD (especially when macula threatened)
- endophthalmitis

**Life Threatening**
- proptosis (rule out cavernous sinus fistula or thrombosis)
- CN III palsy with dilated pupil (intracranial aneurysm or neoplastic lesion)
- papilledema (must rule out intracranial mass lesion)
- orbital cellulitis
- GCA
- leukocoria: white reflex (absent red reflex, must rule out retinoblastoma)

### The Ocular Examination

#### Visual Acuity – Distance
- Snellen Acuity (Figure 5) = testing distance (usually 20 feet or 6 meters) / smallest line patient can read on the chart
  - e.g. 20/40 = what the patient can see at 20 feet (numerator), what a “normal” person can see at 40 feet (denominator)
- distance visual acuity should be tested with distance glasses on in order to obtain best corrected visual acuity
- testing hierarchy for low vision: Snellen acuity (20/x) → counting fingers at a given distance (CF) → hand motion (HM) → light perception with projection (LP with projection) → light perception (LP) → no light perception (NLP)
- legal blindness is BCVA that is ≤20/200 in best eye

---

**Example 1**
- SC 20/40 – 1
- 20/80 + 2 → 20/25 PH

**Example 2**
- CC CF 3’ HM

Note: RIGHT EYE visual acuity always listed on top.
- V Vision
- SC Without correction
- CC With correction
- 20/40 -1 All except one letter of 20/40
- 20/80+2 All of 20/80 plus two letters of 20/70
- PH Visual acuity with pinhole correction
- CF Counting fingers
- HM Hand motion

---

**Normal Infant and Child Visual Acuity**
- 6-12 mo: 20/120
- 1-2 yr: 20/60
- 2-4 yr: 20/20
Visual Acuity – Near
- use pocket vision chart (Rosenbaum Pocket Vision Screener)
- record Jaeger (J) or Point number and testing distance (usually 30 cm) e.g. J2 @ 30 cm
- conversion to distance VA possible (e.g. immobile patient, no distance chart available)

Visual Acuity for Infants, Children, Non-English Speakers, and Dysphasics
- newborns
  - VA cannot be tested
- 3 mo - 3 yr (can only assess visual function, not acuity)
  - test each eye for fixation symmetry using an interesting object
  - normal function noted as “CSM” = central, steady, and maintained
- 3 yr until alphabet known
  - pictures or letter cards/charts such as HOTV or Sheridan-Gardner test (children point to optotypes on a provided matching card)
  - tumbling “E” chart

Color Vision
- test with Ishihara pseudoisochromatic plates
- record number of correctly identified plates presented to each eye, specify incorrect plates
- important for testing optic nerve function (e.g. optic neuritis, chloroquine use, thyroid ophthalmopathy)
- note: red-green color blindness is sex-linked and occurs in 7-10% of males

VISUAL FIELDS
- test “visual fields by confrontation” (4 quadrants, each eye tested separately) for estimation of visual field loss
- accurate, quantifiable assessment with automated visual field testing (Humphrey or Goldmann) or Tangent Screen
- use Amsler grid (tested separately) to test for central or paracentral scotomas (island-like gaps in the vision) in patients with AMD

PUPILS
- use reduced room illumination with patient focusing on distant object to prevent “near reflex”
- examine pupils for shape, size, symmetry, and reactivity to light (both direct and consensual response)
- RAPD with swinging flashlight test
- test pupillary constriction portion of near reflex by bringing object close to patient’s nose
- “normal” pupil testing often noted as PERLA (pupils equal, round, and reactive to light and accommodation)

ANTERIOR CHAMBER DEPTH
- shine light tangentially from temporal side
- if >2/3 of nasal side of iris in shadow → shallow anterior chamber

The van Herick Method
- shine thin-angled slit beam onto the peripheral cornea of each eye
- estimate depth between the posterior surface of the cornea and the iris as a proportion of corneal thickness
- follow-up with gonioscopy for ratios ≤1/4

Gonioscopy
- allows direct visualization of the angle structures
- angle considered open if trabecular meshwork, scleral spur, and iris processes are visualized
- angle considered narrow (occludable) if only Schwalbe’s line or a small portion of the trabecular meshwork is seen

EXTRAOCULAR MUSCLES
Alignment
- Hirschberg corneal reflex test
  - examine in primary position of gaze (i.e. straight ahead) with patient focusing on distant object
  - shine light into patient’s eyes from ~30 cm away
  - corneal light reflex should be symmetric and at the same position on each cornea
- strabismus testing as indicated (cover test, cover-uncover test, prism testing) (see Strabismus, OP38)
Movement

- examine movement of eyeball through six cardinal positions of gaze
- ask patient if diplopia is present in any position of gaze
- observe for horizontal, vertical, or rotatory nystagmus (rhythmic, oscillating movements of the eye)
- resolving horizontal nystagmus at end-gaze is usually normal
- see sidebar for cranial nerve innervation of extraocular muscles

Diplopia

- major symptom associated with dysfunction of extraocular muscles or abnormalities of the motor nerves innervating these muscles
- must determine whether diplopia is monocular or binocular
- determine whether diplopia was sudden onset (due to an acute event such as ischemia) or gradual (due to progressive process such as tumor or inflammation)
- with myasthenia gravis, diplopia and ptosis usually worsen on prolonged upgaze; can rule out with a Tensilon® test (see Neurology, N38)
- if suspect compressive lesion (most commonly seen with CN III palsy with a blown pupil), need MRI and angiography to rule out aneurysm or tumor
- new-onset diplopia that disappears with occlusion of either eye (binocular diplopia) needs urgent referral while chronic binocular diplopia and monocular diplopia should be referred non-urgently

EXTERNAL EXAMINATION

- four Ls
  - lymph nodes (preauricular, submandibular)
  - lids
  - lashes
  - lacrimal system

SLIT-LAMP EXAMINATION

- systematically examine all structures of the anterior segment and anterior vitreous (for structures see Figure 1)
- when necessary, use
  - fluorescein dye: stains Bowman's membrane in de-epithelialized cornea; dye appears green with cobalt blue filtered light
  - Rose Bengal dye: stains devitalized corneal epithelium
- special lenses (78 or 90 D) used with the slit-lamp allow a binocular, stereoscopic view of the fundus and vitreous

Figure 9. Diplopia

**Diplopia**

- Cover one eye
  - Diplopia remains
    - Monocular
  - Diplopia disappears
    - Binocular
- Optical Aberration:
  - Cataract
  - Uncorrected refractive error
  - Presbyopia
  - Keratopathy

  - CNS Lesion: INO
  - OMMN Lesion: CN III, IV, VI palsy
  - NMJ Lesion: Myasthenia gravis
  - EOM Lesion: Restrictive ophthalmopathy

Figure 10. Slit-lamp examination note

**Aqueous Flare**

- Resembles dust particles in a beam of light
- Results from protein leaking from blood vessels
- Distinguish from aqueous cells (individual cells in anterior chamber)

Note: RIGHT EYE drawn on the left, LEFT EYE drawn on the right (as if looking at patient’s face)

- Lids/lashes: Conjunctiva/sclera/episclera
- Cornea/sclera/anterior surface of lens
- Litt/Lid/Cornea
- OK/Clear
- SC/Sclera, conjunctiva
- AC/Anterior chamber
- d+q/Deep (not shallow) and quiet (no cells in AC)
- Ns/Nuclear sclerosis (cataract)

© Sherry H. Lai 2006
TONOMETRY
- measurement of IOP
- normal range is 10-21 mmHg (average 15 mmHg)
- IOP has diurnal variation, so always record the time of day at which the measurement was taken
- commonly measured by
  - Goldmann Applanation Tonometry (GAT): gold standard, performed using the slit-lamp with special tip (prism)
  - Tono-Pen®: benefit is portability and use of disposable probe tips. Use when cornea is scarred/asymmetric (GAT inaccurate)
  - air puff (non-contact and least reliable)
- use topical anesthetic for GAT and Tono-Pen

OPHTHALMOSCOPY/FUNDOSCOPY
- performed with
  - direct ophthalmoscope (monocular with small field of view, only posterior pole visualized)
  - slit-lamp with 78 or 90 D lens (binocular view, visualization to mid-periphery of retina)
  - indirect ophthalmoscopy with headlamp and 20 or 28 D lens (binocular view, visualization of entire retina to ora serrata/edge of retina)
- best performed with pupils dilated (for list of mydriatics and cycloplegics see Table 11, OP45)
  1. assess red reflex
     - light reflected off the retina produces a “red reflex” when viewed from ~1 foot away
     - anything that interferes with the passage of light will diminish the red reflex (e.g. large vitreous hemorrhage, cataract)
  2. examine the posterior segment of the eye (Figure 10)
     - vitreous
     - optic disc (color, C:D ratio, sharpness of disc margin)
     - macula (~2 disc diameters temporal to disc), fovea (foveal light reflex)
     - retinal vessels
     - retinal background
- contraindications to pupillary dilatation
  - shallow anterior chamber – can precipitate acute angle-closure glaucoma
  - iris-supported anterior chamber lens implant
  - potential neurologic abnormality requiring pupil evaluation
  - use caution with cardiovascular disease – mydriatics may cause tachycardia

OPTICS
- REFRACTION
  - two techniques used
    - flash/streak retinoscopy: refractive error determined objectively by the examiner using lenses and retinoscope
    - manifest: subjective trial using loose lenses or a phoropter (device the patient looks through that is equipped with lenses)
  - a typical lens prescription would contain
    - sphere power in D (measurement of refractive power of lens, equal to reciprocal of focal length in meters)
    - cylinder power in D to correct astigmatism (always positive value)
    - axis of cylinder in degrees
    - “add” (bifocal/progressive reading lens) for presbyopes
      - e.g. -1.50 + 1.00 x 120 degrees, add +2.00
- REFRACTIVE EYE SURGERY
  - permanently alters corneal refractive properties by ablating tissue to change curvature of the cornea
  - used for correction of myopia, hyperopia, and astigmatism
  - common types include PRK and LASIK (see Surgical Ophthalmology, OP44)
  - potential risks/side-effects: infection, under/overcorrection, decreased night vision (nyctalopia), corneal haze, dry eyes, regression, complete sever of corneal flap (LASIK only)

Central Corneal Thickness (CCT)
Average CCT = 550 µm
By GAT, IOP is over-estimated with thick corneas and under-estimated with thin corneas

Quick Tips for Direct Ophthalmoscopy
- Examine in a dark room
- Ask patient to focus on a distant object
- Match ophthalmoscope light aperture to size of pupil (i.e. smaller aperture for undilated eye)
- Use moderate light intensity
- Use your left/right eye and hand to examine patient’s left/right eye respectively
- Get in close! Proximity to patient’s eye is key. You may rest your hand on the patient’s cheek

Structures Responsible for Refractive Power
- Cornea (2/3)
- Lens (1/3)

Myopia
LMN
Long globe
Myopic
Negative correction/Nearsighted
<table>
<thead>
<tr>
<th>Pathophysiology</th>
<th>Clinical Features</th>
<th>Treatment</th>
<th>Complications</th>

<td>Emmetropia</td>
<td>• Image of distant objects focus exactly on the retina (Figure 12)</td>
<td>• No refractive error</td>
<td></td>
</tr>
<tr>
<td>Myopia</td>
<td>• Globe too long relative for refractive mechanisms, or refractive mechanisms too strong</td>
<td>• “Near-sightedness”</td>
<td>• Retinal tear/detachment, macular hole, open angle glaucoma</td>
</tr>
<tr>
<td></td>
<td>• Light rays from distant object focus in front of retina → blurring of (distance) vision (Figure 12)</td>
<td>• Usually presents in 1st or 2nd decade, stabilizes in 2nd and 3rd decade; rarely begins after age 25 except in patients with DM or cataracts</td>
<td>Other complications that are not prevented with refractive correction</td>
</tr>
<tr>
<td></td>
<td>• Blurring of distance vision; near vision usually unaffected</td>
<td>• Prevalence: 30-40% in U.S. population</td>
<td></td>
</tr>
<tr>
<td>Hyperopia</td>
<td>• Globe too short relative to refractive mechanisms, or refractive mechanisms too weak</td>
<td>• “Far-sightedness”</td>
<td>• Angle-closure glaucoma, particularly later in life as lens enlarges</td>
</tr>
<tr>
<td></td>
<td>• Light rays from distant object focus behind retina → blurring of near = distant vision (Figure 12)</td>
<td>• Youthful eyes do not require glasses (still have sufficient accommodative ability to focus image on retina), but may develop accommodative esotropia (see Strabismus, OP38)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• May be developmental or due to any etiology that shortens globe</td>
<td>• 30s-40s: blurring of distance vision due to decreased accommodation</td>
<td></td>
</tr>
<tr>
<td>Astigmatism</td>
<td>• Light rays not refracted uniformly in all meridians due to non-spherical surface of cornea or non-spherical lens (e.g. football-shaped)</td>
<td>• Affects approximately 30% of population, with prevalence increasing with age</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Two types:</td>
<td>• Mild astigmatism unnoticeable</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Regular – curvature uniformly different in meridians at right angles to each other</td>
<td>• Higher amounts of astigmatism may cause blurry vision, squinting, asthenopia, or headaches</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Irregular – distorted cornea caused by injury, keratoconus (cone-shaped cornea), corneal scar, or severe dry eye</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Presbyopia</td>
<td>• Normal aging process (&gt;40 yr)</td>
<td>• If initially emmetropic, person begins to hold reading material farther away, but distance vision remains unaffected</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Hardening/reduced deformability of lens results in decreased accommodative ability</td>
<td>• If initially myopic, person removes distance glasses to read</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Accommodative power is 14D at age 10, diminishes to 3.5D by age 40</td>
<td>• If initially hyperopic, symptoms of presbyopia occur earlier</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Near images cannot be focused onto the retina (focus is behind the retina as in hyperopia)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Anisometropia</td>
<td>• Difference in refractive errors between eyes</td>
<td></td>
<td>Second most common cause of amblyopia in children</td>

### Imaging Modalities

- **adaptive optics scanning laser ophthalmology – optical coherence tomography (SLO-OCT)**
  - combines the surface detail of confocal ophthalmoscopy with the internal detail of OCT
  - allows 3D OCT images, volume and area maps, and retinal thickness maps, at the resolution of living rods and cones
  - can visualize photoreceptors, nerve fibers and blood cells in retinal capillaries
- **CT, MRI**
  - orbital imaging, particularly in orbital trauma and neuro-ophthalmology
- **fluorescein angiography**
  - non-invasive evaluation of vascular pattern of the fundus
  - commonly used in AMD, DR, retinal vascular diseases
- **indocyanine green angiography**
  - uses infra-red light and intravenous ICG dye for imaging of choroidal structure
  - particularly useful to detect polypoidal vasculopathy (variant of AMD) more commonly present among Asian patients
• HRT
  ▪ confocal scanning laser tomography of retinal nerve head and surrounding nerve fiber layer
  ▪ used to assess extent of structural glaucomatous changes

• OCT
  ▪ non-invasive, cross-sectional, high-resolution imaging of vitreous, retinal layers, optic nerve
  ▪ commonly used to assess macular pathology/edema/holes/cysts, AMD progression, epiretinal membrane, RD

• anterior segment optical coherence tomography (AS-OCT)
  ▪ non-invasive, cross-sectional, high-resolution imaging of cornea, aqueous, iris and lens

• perimetry
  ▪ quantitative evaluation of visual fields, used to screen for scotomas and monitor progression (e.g. in glaucoma)

• ultrasonography
  ▪ evaluation of orbit in real-time. A-scans (one-dimensional), B-scans (two-dimensional), and Doppler are all used (e.g. large RDs, foreign bodies, monitoring intraocular tumors)

### Preseptal Cellulitis

- infection of soft tissue anterior to orbital septum

#### Etiology
- usually follows periorbital trauma or dermal infection

#### Clinical Features

**Treatment**
- systemic antibiotics (suspect *H. influenzae* in children; *S. aureus* or *Streptococcus* in adults)
  - e.g. amoxicillin-clavulanic acid
- if severe or child <1 yr, treat as orbital cellulitis

### Orbital Cellulitis

- **OCULAR and MEDICAL EMERGENCY**
- inflammation of orbital contents posterior to orbital septum
- common in children, elderly, and immunocompromised

#### Etiology
- usually secondary to sinus/facial/tooth infections or trauma, can also arise from preseptal cellulitis

#### Clinical Features

**Treatment**
- admit, blood cultures x2, orbital CT, IV antibiotics (ceftiraxone + vancomycin) for 1 wk
- surgical drainage of abscess with close follow-up, especially in children

Orbital cellulitis is life-threatening if untreated (mortality of 17-20% without antibiotic use); prompt diagnosis and treatment is essential
Complications
- optic nerve inflammation, cavernous sinus thrombosis, meningitis, and brain abscess with possible loss of vision, death

Role of Oral Corticosteroids in Orbital Cellulitis

Purpose: To evaluate the role of oral corticosteroids as an anti-inflammatory adjunct for the treatment of orbital cellulitis.

Study: RCT. Patients with acute onset (within 14 d) of orbital cellulitis with or without abscess. 21 patients total (7 patients in group 1: standard intravenous antibiotics; 14 patients in group 2: adjuvant steroids).

Results: Patients in group 2 showed earlier resolution of periorbital edema, conjunctival chemosis, pain, proptosis, and EOM deficits, including decreased duration of intravenous antibiotics and hospital stay (p<0.05 for all).

Conclusion: The use of oral steroids as an adjunct to intravenous antibiotics for orbital cellulitis may decrease inflammatory symptoms with a low risk of worsening infection.

Lacrimal Apparatus
- tear film made up of three layers
  - outer oily layer (reduces evaporation): secreted by the Meibomian glands
  - middle watery layer (forms the bulk of the tear film): constant secretion from conjunctival glands and reflex secretion by lacrimal gland with ocular irritation or emotion
  - inner mucinous layer (aids with tear adherence to cornea): secreted by conjunctival goblet cells
- tears drain from the eyes through the upper and lower lacrimal puncta → superior and inferior canaliculi → lacrimal sac → nasolacrimal duct → nasal cavity behind inferior concha (Figure 3)

Dry Eye Syndrome (Keratoconjunctivitis Sicca)

Etiology
- aqueous-deficient (lacrimal pathology)
  - Sjögren syndrome (autoimmune etiology e.g. RA, SLE)
  - non-Sjögren syndrome (idiopathic age-related disease; lacrimal gland scarring e.g. trachoma; decreased secretion e.g. contact lenses, CN VII palsy, anticholinergics, antihistamines, diuretics, β-blockers)
- evaporative (normal lacrimal function, excessive evaporation of aqueous layer)
  - Meibomian gland dysfunction (posterior blepharitis)
  - vitamin A deficiency (xerophthalmia with goblet cell dysgenesis)
  - eyelid abnormalities e.g. ectropion, CN VII palsy (decreased blinking)
  - preserved topical ocular medications
  - contact lenses, allergic conjunctivitis
- overlap of mixed etiologies common

Clinical Features
- dry eyes, red eyes, foreign body sensation, blurred vision, tearing
- slit-lamp exam: decreased tear meniscus, decreased tear break-up time (normally should be 10 s), SPK

Investigations
- surface damage observed with fluorescein/Rose Bengal staining
- decreased distance in Schirmer’s test

Complications
- erosions and scarring of cornea

Treatment
- medical: preservative-free artificial tears up to q1h and ointment at bedtime (preservative toxicity becomes significant if used more than q1h PRN)
  - for severe cases, cyclosporine ophthalmic emulsion 0.05% (Restasis®) can be used
- procedural: punctal occlusion (punctal plug insertion), lid taping, tarsorrhaphy (sew lids together) if severe
- treat underlying cause

Long-term use of artificial tears with preservatives should be avoided when treating dry eyes
**Epiphora (Excessive Tearing)**

**Etiology**
- emotion, pain
- environmental stressor (cold, wind, pollen, sleep deprivation)
- lid/lash malposition: ectropion, entropion, trichiasis
- inflammatory: conjunctivitis, uveitis, keratitis, corneal foreign body
- dry eyes (reflex tearing)
- lacrimal drainage obstruction (congenital failure of canalization, aging, rhinitis, dacrocystitis)
- paradoxical gustatory lacrimation reflex (crocodile tears)

**Investigations**
- using fluorescein dye, examine for punctal reflux by pressing on canaliculi
- Jones dye test: fluorescein placed in conjunctival cul-de-sac, and cotton applicator placed in nose to detect flow (i.e. rule out lacrimal drainage obstruction)

**Treatment**
- lid repair for ectropion or entropion
- eyelash removal for trichiasis
- punctal irrigation
- nasolacrimal duct probing (infants)
- tube placement: temporary (Crawford) or permanent (Jones)
- surgical: dacryocystorhinostomy (see *Surgical Ophthalmology, OP44*) – forming a new connection between the lacrimal sac and the nasal cavity

**Dacryocystitis**
- acute or chronic infection of the lacrimal sac
- most commonly due to obstruction of the nasolacrimal duct
- commonly associated with *S. aureus, S. pneumoniae, Pseudomonas* species

**Clinical Features**
- pain, swelling, redness over lacrimal sac at medial canthus
- epiphora, crusting, ± fever
- digital pressure on the lacrimal sac may extrude pus through the punctum
- in the chronic form, epiphora may be the only symptom

**Treatment**
- warm compresses, nasal decongestants, systemic and topical antibiotics
- if chronic, obtain cultures by aspiration
- once infection resolves, consider dacryocystorhinostomy (see *Surgical Ophthalmology, OP44*)

**Dacryoadenitis**
- inflammation of the lacrimal gland (outer third of upper eyelid)
- acute causes: *S. aureus*, mumps, EBV, herpes zoster, *N. gonorrhoeae*
- chronic causes (often bilateral): lymphoma, leukemia, sarcoidosis, tuberculosis, thyroid ophthalmopathy

**Clinical Features**
- pain, swelling, tearing, discharge, redness of the outer region of the upper eyelid
- chronic form is more common and may present as painless enlargement of the lacrimal gland

**Treatment**
- supportive: warm compresses, oral NSAIDs
- systemic antibiotics if bacterial cause
- if chronic, treat underlying disorder

**Lids and Lashes**

**Lid Swelling**

**Etiology**
- commonly due to allergy, with shriveling of skin between episodes
- dependent edema on awakening (e.g. CHF, renal or hepatic failure)
- orbital venous congestion due to mass or cavernous sinus fistula
- dermatochalasis (loose skin due to aging or heredity)
- lid cellulitis, thyroid disease (e.g. myxedema), trauma, chemosis
**Ptosis**

- drooping of upper eyelid

**Etiology**

- aponeurotic: disinsertion or dehiscence of levator aponeurosis (most common)
  - associated with advancing age, trauma, surgery, pregnancy, chronic lid swelling
- mechanical
  - incomplete opening of eyelid due to mass or scarring
- neuromuscular
  - myasthenia gravis (neuromuscular palsy), myotonic dystrophy
  - CN III palsy
  - Horner's syndrome (see Constricted Pupil, Horner’s Syndrome, OP32)
- congenital
- pseudoptosis (e.g. dermatochalasis, enophthalmos, contralateral exophthalmos)

**Treatment**

- surgery

**Trichiasis**

- eyelashes turned inwards
  - may result from chronic inflammatory lid diseases (e.g. blepharitis), Stevens-Johnson syndrome, trauma, burns
  - patient complains of red eye, foreign body sensation, tearing
  - may result in corneal ulceration and scarring

**Treatment**

- topical lubrication, eyelash plucking, electrolysis, cryotherapy

**Entropion**

- lid margin turns in towards globe causing tearing, foreign body sensation, and red eye
  - most commonly affects lower lid
  - may cause abrasions with secondary corneal scarring

**Etiology**

- involutional (aging)
- cicatricial (herpes zoster, surgery, trauma, burns)
- orbicularis oculi muscle spasm
- congenital

**Treatment**

- lubricants, evert lid with tape, surgery

**Ectropion**

- lid margin turns outward from globe causing tearing and possibly exposure keratitis

**Etiology**

- involutional (aging)
- paralytic (CN VII palsy)
- cicatricial (burns, trauma, surgery)
- mechanical (lid edema, tumor, herniated fat)
- congenital

**Treatment**

- topical lubrication, surgery

**Hordeolum (Stye)**

- acute inflammation of eyelid gland: either Meibomian glands (internal lid) or glands of Zeis (modified sweat gland) or Moll (modified sebaceous gland in external lid)
- infectious agent is usually *S. aureus*
- painful, red swelling of lid

**Treatment**

- warm compresses, lid care, gentle massage
- topical antibiotics (e.g. erythromycin ointment bid)
- usually resolves in 2-5 d
Chalazion
- chronic granulomatous inflammation of Meibomian gland often preceded by an internal hordeolum
- acute inflammatory signs are usually absent
- differential diagnosis: basal cell carcinoma, sebaceous cell adenoma, Meibomian gland carcinoma

Treatment
- warm compresses
- if no improvement after 1 mo, consider incision and curettage
- chronic recurrent lesion must be biopsied to rule out malignancy

Blepharitis
- inflammation of lid margins

Etiology
- two main types
  - staphylococcal (S. aureus): ulcerative, dry scales
  - seborrheic: no ulcers, greasy scales

Clinical Features
- itching, tearing, foreign body sensation
- thickened, red lid margins, crusting, discharge with pressure on lids ("toothpaste sign")

Complications
- recurrent chalazia
- conjunctivitis
- keratitis (from poor tear film)
- corneal ulceration and neovascularization

Treatment
- warm compresses and lid scrubs with diluted "baby shampoo"
- topical or systemic antibiotics as needed
- if severe, ophthalmologist may prescribe a short course of topical corticosteroids

Xanthelasma
- eyelid xanthoma (lipid deposits in dermis of lids)
- appear as pale, slightly elevated yellowish plaques or streaks
- most commonly on the medial upper lids, often bilateral
- associated with hyperlipidemia (approximately 50% of patients)
- common in the elderly, more concerning in the young

Treatment
- excision for cosmesis only, commonly recurs

Conjunctiva
- thin, vascular mucous membrane/epithelium
- bulbar conjunctiva: lines sclera to limbus (junction between cornea and sclera)
- palpebral (tarsal) conjunctiva: lines inner surface of eyelid

Pinguecula
- yellow-white subepithelial deposit of hyaline and elastic tissue adjacent to the nasal or temporal limbus, sparing the cornea
- associated with sun and wind exposure, aging
- common, benign, sometimes enlarges slowly
- may be irritating due to abnormal tear film formation over the deposits
- surgery for cosmesis only
- irritative symptoms may be treated with lubricating drops
**Pterygium**
- fibrovascular triangular encroachment of epithelial tissue onto the cornea, usually nasally
- may induce astigmatism, decrease vision
- excision for chronic inflammation, threat to visual axis, cosmesis
- irritative symptoms may be treated with lubricating drops
- one-third recur after excision, lower recurrence with conjunctival autograft (5%)

**Subconjunctival Hemorrhage**
- blood beneath the conjunctiva, otherwise asymptomatic
- idiopathic or associated with trauma, Valsalva maneuver, bleeding disorders, HTN
- give reassurance if no other ocular findings, resolves spontaneously in 2-3 wk
- if recurrent, consider medical/hematologic workup

**Conjunctivitis**

**Etiology**
- infectious
  - bacterial, viral, chlamydial, fungal, parasitic
- non-infectious
  - allergic: atopic, seasonal, giant papillary conjunctivitis (contact lens wearers)
  - toxic: irritants, dust, smoke, irradiation
  - secondary to another disorder: dacryocystitis, dacryoadenitis, cellulitis, Kawasaki disease

**Clinical Features**
- red eye (conjunctival injection often with limbal pallor), chemosis, subepithelial infiltrates
- itching, foreign body sensation, tearing, discharge, crusting of lashes in the morning, lid edema
- preauricular and/or submandibular nodes
- follicles: pale lymphoid elevations of the conjunctiva
- papillae: fibrovascular elevations of the conjunctiva with central network of finely branching vessels (cobblestone appearance)

**ALLERGIC CONJUNCTIVITIS**

**Atopic**
- associated with rhinitis, asthma, dermatitis, hay fever
- small papillae, chemosis, thickened and erythematous lids, corneal neovascularization
- seasonal (pollen, grasses, plant allergens)
- treatment: cool compresses, antihistamine, mast cell stabilizer (e.g. ketotifen, olopatadine)

**Giant Papillary Conjunctivitis**
- immune reaction to mucus debris on lenses in contact lens wearers
- large papillae form on superior palpebral conjunctiva
- treatment: clean, change or discontinue use of contact lens

**Vernal Conjunctivitis**
- large papillae (cobblestones) form on superior palpebral conjunctiva with corneal ulcers and keratitis
- seasonal (warm weather)
- occurs in children, lasts for 5-10 yr then resolves
- treatment: consider topical steroid, topical cyclosporine (by ophthalmologist)

**VIRAL CONJUNCTIVITIS**
- serous discharge, lid edema, follicles
- subepithelial corneal infiltrates
- may be associated with rhinorrhea
- preauricular node often palpable and tender
- initially unilateral, often progresses to the other eye
- mainly due to adenovirus – highly contagious for up to 12 d

**Treatment**
- cool compresses, topical lubrication
- usually self-limiting (7-12 d)
- proper hygiene is very important
BACTERIAL CONJUNCTIVITIS
- purulent discharge, lid swelling, papillae, conjunctival injection, chemosis
- common agents include *S. aureus, S. pneumoniae, H. influenzae* and *M. catarrhalis*
- in neonates or if sexually active must consider *N. gonorrhoeae* (invades cornea to cause keratitis)
- *C. trachomatis* is the most common cause in neonates

Treatment
- topical broad-spectrum antibiotic
- systemic antibiotics if indicated, especially in neonates and children
- usually a self-limited course of 10-14 d if no treatment, 1-3 d with treatment

CHLAMYDIAL CONJUNCTIVITIS
- caused by *C. trachomatis*
- affects neonates (ophthalmia neonatorum) on day 3-5, sexually active individuals
- causes trachoma and inclusion conjunctivitis

Trachoma
- leading infectious cause of blindness in the world
- severe keratoconjunctivitis leads to corneal abrasion, ulceration, and scarring
- initially, follicles on superior palpebral conjunctiva
- treatment: topical and systemic tetracycline

Inclusion Conjunctivitis
- chronic conjunctivitis with follicles and subepithelial infiltrates
- most common cause of conjunctivitis in newborns
- prevention: topical erythromycin at birth
- treatment: topical and systemic tetracycline, doxycycline, or erythromycin

Sclera
- white fibrous outer protective coat of the eye, composed of irregularly distributed collagen bundles
- continuous with the cornea anteriorly and the dura of the optic nerve posteriorly
- episclera is a thin layer of vascularized tissue between the sclera and conjunctiva

Episcleritis
- immunologically mediated inflammation of episclera
- 1/3 bilateral; simple (80%) or nodular (20%)
- more frequent in women than men (3:1)

Etiology
- mostly idiopathic
- in 1/3 of cases, associated with collagen vascular diseases, infections (herpes zoster, herpes simplex, syphilis), inflammatory bowel disease, rosacea, atopy

Clinical Features
- usually asymptomatic; may have discomfort, heat sensation, red eye (often interpalpebral), rarely pain
- sectoral or diffuse injection of radially-directed vessels, chemosis, small mobile nodules
- blanches with topical phenylephrine (constricts superficial conjunctival vessels)

Treatment
- generally self limited, recurrent in 2/3 of cases
- topical steroid for 3-5 d if painful (prescribed and monitored by ophthalmologist)

Scleritis
- usually bilateral: diffuse, nodular, or necrotizing
- anterior scleritis: pain radiating to face, may cause scleral thinning, in some cases necrotizing
- posterior scleritis: rapidly progressive blindness, may cause exudative RD
- more common in women and elderly
Etiology
- may be a manifestation of systemic disease
- collagen vascular disease, e.g. SLE, RA, ankylosing spondylitis
- granulomatous, e.g. tuberculosis, sarcoidosis, syphilis
- metabolic, e.g. gout, thyrotoxicosis
- infectious, e.g. S. aureus, S. pneumoniae, P. aeruginosa, herpes zoster
- chemical or physical agents (e.g. thermal, alkali, or acid burns)
- idiopathic

Clinical Features
- severe pain, photophobia, red eye, decreased vision
- pain is best indicator of disease progression
- inflammation of scleral, episcleral, and conjunctival vessels
- may have anterior chamber cells and flare, corneal infiltrate, scleral thinning
- sclera may have a blue hue (best seen in natural light), due to rearranged scleral fibers
- scleral edema or thinning
- failure to blanch with topical phenylephrine

Treatment
- systemic NSAID or steroid (topical steroids are not effective)
- treat underlying etiology

Cornea
- function
  - transmission of light
  - refraction of light (2/3 of total refractive power of eye)
  - barrier against infection, foreign bodies
- transparency due to avascularity, uniform structure and deturgescence (relative dehydration)
- 6 layers (anterior to posterior): epithelium, Bowman’s membrane, stroma, Dua’s layer, Descemet’s membrane, endothelium (dehydrates the cornea; dysfunction leads to corneal edema). A new corneal layer was discovered by H. Dua in 2013 is characterized as a pre-Descemet’s membrane
- extensive sensory fiber network (V1 distribution); therefore abrasions and inflammation (keratitis) are very painful

Foreign Body
- foreign material in or on cornea
- may have associated rust ring if metallic
- patients may note tearing, photophobia, foreign body sensation, red eye
- signs include foreign body, conjunctival injection, epithelial defect that stains with fluorescein, corneal edema, anterior chamber cells/flare

Complications
- abrasion, infection, scarring, rust ring, secondary iritis

Treatment
- remove under magnification using local anesthetic and sterile needle or refer to ophthalmology (depending on depth and location)
- treat as per corneal abrasion

Corneal Abrasion
- epithelial defect usually due to trauma (e.g. fingernails, paper, twigs), contact lens (Figure 14)

Clinical Features (Table 5)
- pain, redness, tearing, photophobia, foreign body sensation
- de-epithelialized area stains with fluorescein dye
- pain relieved with topical anesthetic

Complications
- infection, ulceration, recurrent erosion, secondary iritis

Treatment
- topical antibiotic (drops or ointment)
- consider topical NSAID (caution due to risk of corneal melt with prolonged use), cycloplegic (relieves pain and photophobia by paralyzing ciliary muscle), patch
- most abrasions clear spontaneously within 24-48 h
Recurrent Erosions

- recurrent episodes of pain, photophobia, foreign body sensation with a spontaneous corneal epithelial defect
- usually occurs upon awakening
- associated with improper adherence of epithelial cells to the underlying basement membrane

Etiology

- previous traumatic corneal abrasion
- corneal dystrophy
- idiopathic

Treatment

- as for corneal abrasion until re-epithelialization occurs
- topical hypertonic saline ointment at bedtime for 3 mo, topical lubrication
- bandage contact lens, anterior stromal puncture or phototherapeutic keratectomy for chronic recurrences

Corneal Ulcer

Etiology

- local necrosis of corneal tissue due to infection
- infection is usually bacterial, rarely viral, fungal, or protozoan (Acanthamoeba)
- secondary to corneal exposure, abrasion, foreign body, contact lens use (50% of ulcers)
- also associated with conjunctivitis, blepharitis, keratitis, vitamin A deficiency

Clinical Features

- pain, photophobia, tearing, foreign body sensation, decreased VA (if central ulcer)
- corneal opacity that necroses and forms an excavated ulcer with infiltrative base
- overlying corneal epithelial defect that stains with fluorescein
- may develop corneal edema, conjunctival injection, anterior chamber cells/flare, hypopyon, corneal hypoesthesia (in viral keratitis)
- bacterial ulcers may have purulent discharge, viral ulcers may have watery discharge

Complications

- decreased vision, corneal perforation, iritis, endophthalmitis

Investigations

- Seidel test: fluorescein drop on the cornea under cobalt blue filter is used to detect leaking penetrating lesions; any aqueous leaking will change dark orange dye to bright yellow-green at site of wound

Treatment

- urgent referral to ophthalmology
- culture prior to treatment
- topical antibiotics every hour
- must treat vigorously to avoid complications

Herpes Simplex Keratitis

- usually HSV type 1 (90% of population are carriers)
- may be triggered by stress, fever, sun exposure, immunosuppression

Clinical Features

- pain, tearing, foreign body sensation, red eye, may have decreased vision, eyelid edema
- corneal hypoesthesia
- dendritic (thin and branching) lesion in epithelium that stains with fluorescein
Complications
- corneal scarring (can lead to loss of vision)
- chronic interstitial keratitis due to penetration of virus into stroma
- secondary iritis, secondary glaucoma

Treatment
- topical antiviral such as trifluridine, consider systemic antiviral such as acyclovir
- dendritic debridement
- NO STEROIDS initially – may exacerbate condition
- ophthalmologist must exercise caution if adding topical steroids for chronic keratitis or iritis

Herpes Zoster
- dermatitis of the forehead (CN V1 territory) may involve globe
- Hutchinson's sign: if tip of nose is involved (nasociliary branch of V1) then eye will be involved in approximately 75% of cases
- if no nasal involvement, eye is involved in 1/3 of patients

Clinical Features
- pain, tearing, photophobia, red eye
- corneal edema, pseudodendrite, SPK
- corneal hypoesthesia

Complications
- corneal keratitis, ulceration, perforation and scarring
- secondary iritis, secondary glaucoma, cataract
- muscle palsies (rare) due to CNS involvement
- occasionally severe post-herpetic neuralgia

Treatment
- oral antiviral (acyclovir, valcyclovir, or famciclovir) immediately
- topical steroids, cycloplegia as indicated for keratitis, iritis
- erythromycin ointment if conjunctival involvement

Keratoconus
- bilateral paracentral thinning and bulging (ectasia) of the cornea to form a conical shape
- usually sporadic, but associated with Down's syndrome, atopy, contact lens use (theorized to be related to chronic vigorous eye rubbing)
- associated with breaks in Descemet's and Bowman's membrane
- results in irregular astigmatism, scarring, stromal edema

Treatment
- attempt correction with spectacles or contact lens
- cross-linking treatment may halt or slow disease progression
- intrastromal corneal ring segments can help flatten the corneal cone
- penetrating keratoplasty (corneal transplant) 90% successful
- post-operative complications: endophthalmitis, graft rejection, graft failure, graft dehiscence

Arcus Senilis
- hazy white ring in peripheral cornea, <2 mm wide, clearly separated from limbus
- common, bilateral, benign corneal degeneration due to lipid deposition, part of the aging process
- may be associated with hypercholesterolemia if age <40 yr, check lipid profile
- no associated visual symptoms, no complications, no treatment necessary

Kayser-Fleischer Ring
- brown-yellow-green pigmented ring in peripheral cornea, starting inferiorly
- due to deposition of copper pigment in Descemet's membrane
- associated with Wilson's disease
- no associated symptoms or complications of ring
- treat underlying disease
The Uveal Tract

- uveal tract (from anterior to posterior) = iris, ciliary body, choroid
- vascularized, pigmented middle layer of the eye, between the sclera and the retina

Uveitis

- uveal inflammation which may involve one, or all three parts of the tract
- idiopathic or associated with autoimmune, infectious, granulomatous, malignant causes
- should be managed by an optometrist or ophthalmologist
- anatomically classified as anterior uveitis, intermediate uveitis, posterior uveitis, or panuveitis based on primary site of inflammation

Table 6. Anatomic Classification of Uveitis

<table>
<thead>
<tr>
<th>Location</th>
<th>Anterior Uveitis (Iritis)</th>
<th>Intermediate Uveitis</th>
<th>Posterior Uveitis</th>
</tr>
</thead>
<tbody>
<tr>
<td>Location</td>
<td>Inflammation of iris, usually accompanied by cyclitis (inflammation of ciliary body), both = iridocyclitis</td>
<td>The vitreous is the major site of the inflammation</td>
<td>Inflammation of the choroid and/or retina</td>
</tr>
</tbody>
</table>

Etiology

- Usually idiopathic
- Connective tissue diseases (see Rheumatology, RH8)
  - HLA-B27: reactive arthritis, ankylosing spondylitis, psoriatic arthritis, inflammatory bowel disease
  - Non-HLA-B27: juvenile idiopathic arthritis
- Infectious: syphilis, Lyme disease, toxoplasmosis, TB, HSV, herpes zoster
- Other: sarcoidosis, trauma, large abrasion, post ocular surgery

Clinical Features

- Photophobia (due to reactive spasm of inflamed iris muscle), ocular pain, tenderness of the globe, brow ache (ciliary muscle spasm), decreased VA (in severe cases with hypopyon), lacrimation
- Ciliary flush (perilimbal conjunctival injection), miosis (spasm of sphincter muscle)
- Anterior chamber “cells” (WBC in anterior chamber due to anterior segment inflammation) and “flares” (protein precipitates in anterior chamber secondary to inflammation), hypopyon (collection of neutrophilic exudates inferiorly in the anterior chamber)
- Occasionally keratic precipitates (clumps of cells on corneal endothelium)
- Iritis typically reduces IOP because ciliary body inflammation causes decreased aqueous production; however, severe iritis, or iritis from herpes simplex and zoster may cause an inflammatory glaucoma (trabeculitis)
- Insidious onset of blurred vision, accompanied by vitreous floaters
- Initial symptoms are usually unilateral but inflammatory changes are usually bilateral and asymmetric
- Associated with anterior uveitis, most severe cases of secondary intermediate uveitis
- Vitreous cells, condensations, and snowballs (vitreous aggregates of inflammatory cells)
- Posterior segment ‘snowbank’ = gray-white fibrovascular plaque at the pars plana
- Painless as choroid has no sensory innervation
- Often no conjunctival or scleral injection present
- Decreased VA
- Floaters (debris and inflammatory cells)
- Vitreous cells and opacities
- Hypopyon formation

Complications

- Inflammatory glaucoma
- Cystoid macular edema (30% of cases), cataract, and glaucoma
- Macular edema
- Vitritis
- Neovascularization
- Visual field loss/scotoma

Treatment

- Mydriatics: dilate pupil to prevent formation of posterior synechiae and to decrease pain from ciliary spasm
- Steroids: topical, sub-tenon, or systemic
- Systemic analgesia
- Extensive medical workup may be indicated to rule out secondary causes
- Systemic or sub-tenon/intravitreal steroids and immunosuppressive agents
- Vitrectomy, cryotherapy, or laser photocoagulation to the “snowbank”
- Steroids: sub-tenon, intravitreal, or systemic if indicated (e.g. threat of vision loss)
**Lens**

- consists of an outer capsule surrounding a soft cortex and a firm inner nucleus

**Cataracts**

- any opacity of the lens, regardless of etiology
- most common cause of reversible blindness worldwide
- types: nuclear sclerosis, cortical, posterior subcapsular

**Etiology**

- acquired
  - age-related (over 90% of all cataracts)
  - cataract associated with systemic disease (may have juvenile onset)
    - DM
    - metabolic disorders (e.g. Wilson's disease, galactosemia, homocystinuria)
    - hypocalcemia
  - traumatic (may be rosette shaped)
  - intraocular inflammation (e.g. uveitis)
  - toxic (steroids, phenothiazines)
  - radiation
- congenital
  - high myopia
  - present with altered red reflex or leukocoria
  - treat promptly to prevent amblyopia

**Clinical Features**

- gradual, painless, progressive decrease in VA
- glare, dimness, halos around lights at night, monocular diplopia
- "second sight" phenomenon: patient is more myopic than previously noted, due to increased refractive power of the lens (in nuclear sclerosis only)
  - patient may read without previously needed reading glasses
- diagnose by slit-lamp exam, and by noting changes in red reflex using ophthalmoscope
- may impair view of retina during fundoscopy

**Treatment**

- medical: attempt correction of refractive error, no strong evidence suggesting benefit of vitamin supplementation
- surgical: definitive treatment
  - indications for surgery
    - to improve visual function in patients whose visual loss leads to functional impairment (no need to wait for "ripe" cataract, may postpone surgery as long as one eye has sufficient vision)
    - to aid management of other ocular disease (e.g. cataract that prevents adequate retinal exam or laser treatment of DR)
    - congenital or traumatic cataracts
  - phacoemulsification (phaco = lens)
  - most commonly used surgical technique (see Surgical Ophthalmology, OP44)
  - post-operative complications
    - RD, endophthalmitis, dislocated IOL, macular edema, glaucoma
    - with new foldable IOLs that have truncated edges, <10% of patients get posterior capsular opacification, which should be treated with YAG laser

**Prognosis**

- excellent if not complicated by other ocular disease

**Dislocated Lens (Ectopia Lentis)**

**Etiology**

- associated with Marfan's Syndrome, Ehlers-Danlos type VI, homocystinuria, syphilis, lens coloboma (congenital cleft due to failure of ocular adnexa to complete growth)
- traumatic

---

**Types of Cataracts**

- **Cortical**
  - Radial or spoke-like opacification in the cortex of the lens, either anteriorly or posteriorly
  - Associated with aging and diabetes

- **Nuclear Sclerosis**
  - Yellow to brown ("brunescent") discoloration of the central part of the lens
  - Age-related

- **Posterior Subcapsular**
  - Usually in the posterior of the lens, adjacent to the capsule
  - Associated with steroid use, intraocular inflammation, diabetes, trauma, radiation, aging
Clinical Features
- decreased VA
- may get unilateral diplopia
- iridodenesis (quivering of iris with movement)
- direct ophthalmoscopy may elicit abnormal red reflex

Complications
- cataract, glaucoma, uveitis

Treatment
- surgical correction ± lens replacement

Vitreous
- clear gel (99% water plus collagen fibrils, glycosaminoglycans, and hyaluronic acid) that fills the posterior segment of the eye
- normally adherent to optic disc, pars plana, and along major retinal blood vessels

Posterior Vitreous Detachment

Etiology
- central vitreous commonly shrinks and liquefies with age (syneresis)
- during syneresis, molecules that hold water condense causing vitreous floaters
- liquid vitreous moves between posterior vitreous gel and retina
- vitreous is peeled away and separates from the internal limiting membrane of the neurosensory retina posterior to the vitreous base

Clinical Features
- floaters, flashes of light

Complications
- traction at areas of abnormal vitreoretinal adhesions may cause retinal tears/detachment
- retinal tears/detachment may cause vitreous hemorrhage if bridging retinal blood vessel is torn
- complications more common in high myopes and following ocular trauma (blunt or perforating)

Treatment
- acute onset of PVD requires a dilated fundus exam to rule out retinal tears/detachment
- no specific treatment available for floaters/flashes of light

Vitreous Hemorrhage

Clinical Features
- sudden loss of VA
- may be preceded by many floaters and/or flashes of light
- ophthalmoscopy: no red reflex if large hemorrhage, retina not visible due to blood in vitreous

Treatment
- ultrasound (B-scan) to rule out RD
- expectant: in non-urgent cases (e.g. no DRt), blood usually resorbs in 3-6 mo
- surgical: vitrectomy ± RD repair ± retinal endolaser to possible bleeding sites/vessels

Any time a vitreous or retinal hemorrhage is seen in a child, must rule out child abuse

Floaters: “bugs”, “cobwebs”, or “spots” of vitreous condensation that change with eye position

Weiss Ring: formed by glial tissue around the optic disc that remains attached to the detached posterior vitreous

Although most floaters are benign, new or markedly increased floaters or flashes of light require a dilated fundus exam to rule out retinal tears/detachment
Endophthalmitis and Vitritis

- intraocular infection: acute, subacute, or chronic

**Etiology**
- most commonly a post-operative complication; risk following cataract surgery is <0.1%
- also due to penetrating injury to eye (risk is 3-7%), endogenous spread, and intravitreal injections
- etiology usually bacterial, may be fungal

**Clinical Features**
- painful, red eye, photophobia, discharge
- severely reduced VA, lid edema, proptosis, corneal edema, anterior chamber cells/flare, hypopyon, reduced red reflex
- may have signs of a ruptured globe (severe subconjunctival hemorrhage, hyphema, decreased IOP, etc.)

**Treatment** (see Ocular Trauma, OP42)
- **OCULAR EMERGENCY:** presenting vision best indicates prognosis
- LP or worse: admission, immediate vitrectomy, and intravitreal antibiotics to prevent loss of vision
- HM or better: vitreous tap for culture and intravitreal antibiotics
- topical fortified antibiotics

Retina

- composed of two parts (Figure 2)
  - neurosensory retina: comprises 9 of the 10 retinal layers, including the photoreceptors and the ganglion cell layer
  - retinal pigmented epithelium (RPE) layer: external to neurosensory retina
- macula: rich in cones (for color vision); most sensitive area of retina; looks darker due to increase luteal pigment, lack of retinal vessels, and thinning of retina in this region; 15° temporal and slightly below the optic disc
- fovea: center of macula; responsible for acute, fine vision
- optic disc: slightly oval vertically, pinkish color with centrally depressed yellow cup (normal C:D is <0.5), retinal artery and vein pass through cup
- ora serrata: irregularly-shaped, anterior margin of the retina (can only be visualized with indirect ophthalmoscopy of the far peripheral retina, or through a Goldmann 3 mirror lens)

Central Retinal Artery Occlusion

**Etiology**
- emboli from carotid arteries or heart (e.g. arrhythmia, endocarditis, valvular disease)
- thrombus
- temporal arteritis

**Clinical Features**
- sudden, painless (except in GCA), severe monocular loss of vision
- RAPD
- patient may have experienced transient episodes in the past (amaurosis fugax)
- fundoscopy
  - “cherry-red spot”
  - retinal pallor
  - narrowed arterioles, boxcarring (segmentation of blood in arteries)
  - cotton wool spots (retinal infarcts)
  - cholesterol emboli (Hollenhorst plaques) – usually located at arteriole bifurcations
  - after ~6 wk cherry-red spot recedes and optic disc pallor becomes evident

**Treatment**
- **OCULAR EMERGENCY:** attempt to restore blood flow within 2 h
- the sooner the treatment = better prognosis (irreversible retinal damage if >90 min of complete CRAO)
- massage the globe (compress eye with heel of hand for 10 s, release for 10 s, repeat for 5 min) to dislodge embolus
- decrease IOP
  - topical β-blockers
  - inhaled oxygen-carbon dioxide mixture
  - IV acetazolamide
  - severe IOP: mannitol (draws fluid from eye)
- drain aqueous fluid – anterior chamber paracentesis (carries risk of endophthalmitis)
- treat underlying cause to prevent CRAO in other eye

Remember to inquire about tetanus status in post-traumatic endophthalmitis
Branch Retinal Artery Occlusion

- only part of the retina becomes ischemic resulting in a visual field loss
- more likely to be of embolic etiology than CRAO; need to search for source
- management: ocular massage to dislodge embolus if VA is affected

Central/Branch Retinal Vein Occlusion

- second most frequent “vascular” retinal disorder after DR
- usually a manifestation of a systemic disease (e.g. HTN, DM)
- thrombus occurs within the lumen of the blood vessel

Predisposing Factors
- arteriosclerotic vascular disease
- HTN
- DM
- glaucoma
- hyperviscosity (e.g. polycythemia rubra vera, sickle-cell disease, lymphoma, leukemia)
- drugs (e.g. oral contraceptive pill, diuretics)

Clinical Features
- ± RAPD
- fundoscopy
  - “blood and thunder” appearance
  - diffuse retinal hemorrhages, cotton wool spots, venous engorgement, swollen optic disc, macular edema
- two fairly distinct groups
  - venous stasis/non-ischemic retinopathy
    - no RAPD, VA approximately 20/80
    - mild hemorrhage, few cotton wool spots
    - resolves spontaneously over weeks to months
    - may regain normal vision if macula intact
  - hemorrhagic/ischemic retinopathy
    - usually older patient with deficient arterial supply
    - RAPD, VA approximately 20/200, reduced peripheral vision
    - more hemorrhages, cotton wool spots, congestion
    - poor visual prognosis

Complications
- degeneration of RPE
- neovascularization of retina and iris (secondary rubeosis), leading to secondary glaucoma
- vitreous hemorrhage
- macular edema

Treatment
- no treatment available to restore vision in CRVO/BRVO
- treat underlying cause/contributing factor
- fluorescein angiography to determine extent of retinal non-perfusion (risk of neovascularization)
- retinal laser photocoagulation, or intravitreal anti-VEGF injection to reduce retinal or iris neovascularization and prevent neovascular glaucoma
- macular grid laser photocoagulation for the treatment of macular edema in BRVO, not CRVO, intravitreal or slow-release biodegradable corticosteroid, or anti-VEGF injection is effective in the treatment of macular edema in both CRVO and BRVO

Retinal Detachment

- cleavage in the plane between the neurosensory retina and the RPE
- three types
  - rhegmatogenous (most common)
    - caused by a tear or hole in the neurosensory retina, allowing fluid from the vitreous to pass into the subretinal space
    - tears may be caused by PVD, degenerative retinal changes, trauma, or iatrogenically
    - incidence increases with advancing age, in high myopes, and after ocular surgery/trauma
  - tractional
    - caused by traction (due to vitreal, epiretinal, or subretinal membrane) pulling the neurosensory retina away from the underlying RPE
    - found in conditions such as DR, CRVO, sickle cell disease, ROP, and ocular trauma
  - exudative
    - caused by damage to the RPE resulting in fluid accumulation in the subretinal space
    - main causes are intraocular tumors, posterior uveitis, central serous retinopathy

Efficacy and Safety of Widely Used Treatments for Macular Edema Secondary to Retinal Vein Occlusion: A Systematic Review

BMC Ophthalmol 2014;14:9

Purpose: To assess the efficacy of widely used treatments for macular edema (MO) secondary to retinal vein occlusion (RVO). MO secondary to RVO can cause vision loss due to blockage of the central retinal vein (CRVO) or a branch retinal vein (BRVO).

Outcomes: Mean change in best corrected visual acuity (BCVA) from baseline and/or number of patients gaining at least 10 letters from baseline to 6 months or equivalent time point.

Results: 14 unique RCTs identified. Ranibizumab 0.5 mg produced greater improvements in BCVA at 6 mo compared to sham in BRVO (mean difference 11 letters; 95% CI 7.03-14.17) and CRVO (mean difference 14 letters; 95% CI 10.51-17.69). Improvements in BCVA were also observed with dexamethasone intravitreal implant (IVT) 0.7 mg compared to sham in patients with BRVO or CRVO (mean difference 2.9 letters; 95% CI 0.7-4.3). The difference was significant with BRVO alone, but not CRVO alone. At 36 mo in a large prospective RCT, a greater proportion of patients with BRVO gained >15 letters with laser therapy vs. no treatment (OR 3.16; 95% CI 1.25-8.00), whereas no difference was observed in a 9 mo end point smaller study. Three studies showed no benefit for laser therapy in CRVO.

Conclusions: Both ranibizumab and dexamethasone IVT show significant improvements over previously accepted standard of care (laser therapy) for the treatment of BRVO and CRVO.
Clinical Features
- sudden onset
- flashes of light
  - due to mechanical stimulation of the retinal photoreceptors
- floaters
  - hazy spots in the line of vision which move with eye position, due to drops of blood from torn vessels bleeding into the vitreous
- curtain of blackness/peripheral field loss
  - darkness in one field of vision when the retina detaches in that area
- loss of central vision (if macula “off”)
- decreased IOP (usually 4-5 mmHg lower than the other, normal eye)
- ophthalmoscopy: detached retina is gray-white with surface blood vessels, loss of red reflex
  - + RAPD

Complications
- loss of vision, vitreous hemorrhage, recurrent RD
- a RD is an emergency, especially if the macula is still attached (macula “on”)
- prognosis for visual recovery varies inversely with the amount of time the retina is detached and whether the macula is attached or not

Treatment
- prophylactic: symptomatic tear (flashes or floaters) can be sealed off with laser/cryotherapy, with the goal of preventing progression to detachment
- therapeutic
  - rhegmatogenous
    - scleral buckle procedure (see Surgical Ophthalmology, OP44)
    - pneumatic retinopexy (see Surgical Ophthalmology, OP44)
    - both treatments above are used in combination with localization of retinal tears/holes and subsequent treatment with cryotherapy or laser to create adhesions between the RPE and the neurosensory retina
  - tractional
    - vitrectomy ± membrane removal/scleral buckling/injection of intraocular gas or silicone oil as necessary
  - exudative
    - treat underlying cause

Retinitis Pigmentosa
- worldwide incidence between 1/3,500 and 1/7,000 people
- many forms of inheritance, most commonly autosomal recessive (60%)
- hereditary degenerative disease of the retina manifested by rod > cone photoreceptor degeneration and retinal atrophy

Clinical Features
- night blindness, decreased peripheral vision (“tunnel vision”), decreased central vision (macular changes), glare (from cataract)

Investigations
- fundoscopy: areas of “bone-spicule” pigment clumping in mid-periphery of retina, narrowed retinal arterioles, pale optic disc
- electrophysiological tests: electroretinography (ERG) and electrooculography (EOG) assist in diagnosis

Treatment
- no treatments available to reverse the condition; cataract extraction improves visual function; vitamin A and vitamin E supplementation can reduce progression of disease in some patients

Leber’s Congenital Amaurosis
- worldwide incidence 1/80,000
- inherited degeneration, autosomal recessive
- symptoms: resting nystagmus, sluggish or no papillary response, severe vision loss/blindness
- diagnosis: 11 types, confirmed by genetic testing
- management: no treatments available to reverse the conditions for most forms; one form (LCA2) shown to be successfully treatable by gene replacement using adeno-associated virus CCR5-HRPE65v2 was tolerated. No serious adverse events were recorded. Visual improvement was noted for all patients. All patients reported improved vision in dimly lit environments. Visual fields improved in all patients. Pupillary light reflexes were increased by at least 2 log unit for all patients. Greatest visual improvement was noted in children.

Conclusion: AAV2-HRPE65v2 is safe and improves vision among patients with Leber’s congenital amaurosis.

Vitamin A and Fish Oils for Retinitis Pigmentosa
Purpose: To determine the efficacy and safety of vitamin A and fish oils (docosahexaenoic acid (DHA)) in preventing the progression of RP.
Selection Criteria: RCTs evaluating the effectiveness of vitamin, fish oils, or both as a treatment for RP.
Results: 3 RCTs with 886 participants. No toxicity or adverse events reported. No trial reported a statistically significant benefit of vitamin supplementation on the progression of visual field loss or visual acuity loss. 2 of 3 trials reported a statistically significant difference in ERG amplitudes among some subgroups, but these findings have not been replicated or substantiated in other trials.
Conclusions: There is no clear evidence for benefit of treatment with vitamin A and/or DHA for RP when measuring mean change in visual fields and ERG amplitudes at one year and the mean change in visual acuity at 5 yr follow-up.
Age-Related Macular Degeneration

- leading cause of irreversible blindness in the western world, associated with increasing age, usually bilateral
- F:M
- degenerative changes are concentrated at the macula, thus only central vision is lost; peripheral vision (important for navigation) is maintained so patients can usually maintain an independent lifestyle

Classification

- **Non-Exudative/“Dry” (Non-Neovascular) AMD**
  - most common type of AMD (90% of cases)
  - slowly progressive loss of visual function
  - drusen: yellow-white deposits between the RPE and Bruch’s membrane (area separating inner choroidal vessels from RPE)
  - RPE atrophy: coalescence of depigmented RPE, clumps of focal hyperpigmentation, or hypopigmentation
  - may progress to neovascular AMD

- **Exudative/“Wet” (Neovascular) AMD**
  - 10% of AMD, but 80% of AMD that results in severe visual loss
  - choroidal neovascularization: drusen predisposes to breaks in Bruch’s membrane causing subsequent growth and proliferation of choroidal capillaries
  - may lead to serous detachment of overlying RPE and retina, hemorrhage and lipid precipitates into subretinal space
  - can also lead to an elevated subretinal mass due to fibrous metaplasia of hemorrhagic RD leads to disciform scarring and severe central visual loss

Risk Factors

- female
- increased age
- family history
- smoking
- Caucasian race
- blue irides

Clinical Features

- variable degree of progressive central visual loss
- metamorphopsia (distorted vision characterized by straight parallel lines appearing convergent or wavy) due to macular edema

Investigations

- Amsler grid: held at normal reading distance with glasses on, assesses macular function
- fluorescein angiography: assess the type and location of the choroidal neovascularization – pathologic new vessels leak dye

Treatment

- non-neovascular "dry" AMD
  - monitor, Amsler grid allows patients to check for metamorphopsia
  - low vision aids (e.g. magnifiers, closed-circuit television)
  - anti-oxidants, green leafy vegetables
  - sunglasses/visors
  - see Age-related Eye Disease Study (AREDS)

- neovascular "wet" AMD
  - see Common Medications, OP44
  - laser photocoagulation for neovascularization
  - 50% of choroidal neovascularization cannot be treated initially
  - no definitive treatment for disciform scarring
  - PDT with verteporfin (Visudyne®)
    - IV injection of verteporfin followed by low intensity laser to area of choroidal neovascularization
  - intravitreal injection of anti-VEGF
    - pegaptanib (Macugen®), ranibizumab (Lucentis®), bevacizumab (Avastin®) (see VEGF Inhibitors, OP45)

- fluorescein angiography: assess the type and location of the choroidal neovascularization –
- Amsler grid

Investigations

- metamorphopsia (distorted vision characterized by straight parallel lines appearing convergent or wavy) due to macular edema

Risk Factors

- female
- increased age
- family history
- smoking
- Caucasian race
- blue irides

Clinical Features

- variable degree of progressive central visual loss
- metamorphopsia (distorted vision characterized by straight parallel lines appearing convergent or wavy) due to macular edema

Investigations

- Amsler grid: held at normal reading distance with glasses on, assesses macular function
- fluorescein angiography: assess the type and location of the choroidal neovascularization – pathologic new vessels leak dye

Treatment

- non-neovascular "dry" AMD
  - monitor, Amsler grid allows patients to check for metamorphopsia
  - low vision aids (e.g. magnifiers, closed-circuit television)
  - anti-oxidants, green leafy vegetables
  - sunglasses/visors
  - see Age-related Eye Disease Study (AREDS)

- neovascular "wet" AMD
  - see Common Medications, OP44
  - laser photocoagulation for neovascularization
  - 50% of choroidal neovascularization cannot be treated initially
  - no definitive treatment for disciform scarring
  - PDT with verteporfin (Visudyne®)
    - IV injection of verteporfin followed by low intensity laser to area of choroidal neovascularization
  - intravitreal injection of anti-VEGF
    - pegaptanib (Macugen®), ranibizumab (Lucentis®), bevacizumab (Avastin®) (see VEGF Inhibitors, OP45)
Glaucoma

Definition
• progressive optic neuropathy involving characteristic structural changes to optic nerve head with associated visual field changes
• commonly associated with high IOP, but not required for diagnosis

Background
• aqueous is produced by the ciliary body and flows from the posterior chamber to the anterior chamber through the pupil, and drains into the episcleral veins via the trabecular meshwork and the Canal of Schlemm
• an isolated increase in IOP is termed OHT (or glaucoma suspect) and these patients should be followed for increased risk of developing glaucoma (10% if IOP 20-30 mmHg; 40% if IOP 30-40 mmHg; and most if IOP >40 mmHg)
• pressures >21 mmHg are more likely to be associated with glaucoma; however, up to 50% of patients with glaucoma do not have IOP >21 mmHg
• loss of peripheral vision most commonly precedes central loss
• sequence of events: gradual pressure rise → increased C:D ratio → visual field loss

Investigations
• medical and family history
• VA testing
• slit-lamp exam to assess anterior chamber depth
• ophthalmoscopy to assess the disc features
• tonometry by applanation or indentation to measure IOP
• pachymetry to measure corneal thickness
• future follow-up includes optic disc examination, IOP measurement, and visual field testing to monitor course of disease
Primary Open-Angle Glaucoma

• most common form, >95% of all glaucoma cases
• due to obstruction of aqueous drainage within the trabecular meshwork and its drainage into the Canal of Schlemm
• insidious and asymptomatic, screening is critical for early detection

Major Risk Factors
- elevated IOP (>21 mmHg)
- age: prevalence at 40 yr is 1-2% and at 80 yr is 10%
- ethnicity: African descent
- familial (2-3x increased risk); polygenic

Minor Risk Factors
- myopia
- HTN
- DM
- hyperthyroidism (Graves’ disease)
- chronic topical ophthalmic steroid use in steroid responders – yearly eye exams recommended if >4 wk of steroid use
- previous ocular trauma
- anemia/hemodynamic crisis (ask about blood transfusions in past)

Clinical Features
- asymptomatic initially
- insidious, painless, gradual rise in IOP due to restriction of aqueous outflow
- bilateral, but usually asymmetric
- earliest signs are optic disc changes
  - increased C:D ratio (vertical C:D >0.6)
  - significant C:D asymmetry between eyes (>0.2 difference)
  - thinning, notching of the neuroretinal rim
  - flame shaped disc hemorrhage
  - 360º of peripapillary atrophy
  - nerve fiber layer defect
  - large vessels become nasally displaced
- visual field loss
  - slow, progressive, irreversible loss of peripheral vision
  - paracentral defects, arcuate scotoma, and nasal step are characteristics (see Figure 19)
  - late loss of central vision if untreated

Treatment
- medical treatment: decrease IOP by increasing the drainage and/or decreasing the production of aqueous (see Glaucoma Medications, Table 12, OP45)
  - increase aqueous outflow
    - topical cholinergics
    - topical prostaglandin analogues
    - topical α-adrenergics
  - decrease aqueous production
    - topical β-blockers
    - topical and oral carbonic anhydride inhibitor
    - topical α-adrenergics
- laser trabeculoplasty, cyclophotocoagulation in order to achieve selective destruction of ciliary body (for refractory cases)
- trabeculectomy (see Surgical Ophthalmology, OP44)
- serial optic nerve head examinations, IOP measurements, and visual field testing to monitor disease course

Normal Tension Glaucoma

• POAG with IOP in normal range
• often found in women >60 but may occur earlier
• damage to optic nerve may be due to vascular insufficiency

Treatment
- treat reversible causes
Secondary Open Angle Glaucoma

- increased IOP secondary to ocular/systemic disorders that obstruct the trabecular meshwork
  - steroid-induced glaucoma
  - traumatic glaucoma
  - pigmentary dispersion syndrome
  - pseudoexfoliation syndrome

Primary Angle-Closure Glaucoma

- 5% of all glaucoma cases
- peripheral iris bows forward in an already susceptible eye with a shallow anterior chamber obstructing aqueous access to the trabecular meshwork
- sudden forward shift of the lens-iris diaphragm causes pupillary block, and results in inability of the aqueous to flow from the posterior chamber to the anterior chamber resulting in a sudden rise in IOP

Risk Factors

- hyperopia: small eye, big lens – large lens crowds the angle
- age >70 yr
- female
- family history
- more common in people of Asian and Inuit descent
- mature cataracts
- shallow anterior chamber
- pupil dilation (topical and systemic anticholinergics, stress, darkness)

Clinical Features

- red, painful eye = RED FLAG
- unilateral, but other eye increased risk
- decreased visual acuity, vision acutely blurred from corneal edema
- halos around lights
- nausea and vomiting, abdominal pain
- fixed, mid-dilated pupil
- corneal edema with conjunctival injection
- marked increase in IOP; may be noticeable even to palpation (>40 mmHg)
- shallow anterior chamber ± cells in anterior chamber

Complications

- irreversible loss of vision within hours to days if untreated
- permanent peripheral anterior synchiae, resulting in permanent angle closure

Treatment

- OCULAR EMERGENCY: refer to ophthalmologist for acute angle closure glaucoma
  - laser iridotomy
  - aqueous suppressants and hyperosmotic agents
  - medical treatment (see Glaucoma Medications, Table 12, OP45)
  - miotic drops (pilocarpine) to reverse pupillary block
  - decrease IOP
    - topical β-blockers
    - topical adrenergics
    - topical cholinergics
      - pilocarpine 1-4% q15min, up to q5min
    - systemic carbonic anhydrase inhibitors
      - IV acetazolamide 250-500 mg
    - systemic hyperosmotic agents
      - oral glycerine 1 g/kg
      - IV mannitol 1 g/kg

Secondary Angle-Closure Glaucoma

Uveitis

- inflamed iris adheres to lens (posterior synchiae)

Neovascular Glaucoma

- abnormal blood vessels develop on surface of iris (rubeosis iridis), in the angle, and within the trabecular meshwork
- due to retinal ischemia associated with PDR or CRVO
- treatment with laser therapy to retina reduces neovascular stimulus to iris vessels
Pupils

- pupil size is determined by the balance between the sphincter muscle and the dilator muscle
- sphincter muscle is innervated by the parasympathetic nervous system
  - carried by CN III: pre- and post-ganglionic fibers synapse in ciliary ganglion, and use acetylcholine as the neurotransmitter
- dilator muscle is innervated by the sympathetic nervous system (SNS)
  - first order neuron = hypothalamus → brainstem → spinal cord
  - second order/preganglionic neuron = spinal cord → sympathetic trunk via internal carotid artery → superior cervical ganglion in neck
  - third order/postganglionic fibers originate in the superior cervical ganglion, neurotransmitter is noradrenaline
    - as a diagnostic test, 4-10% cocaine prevents the re-uptake of noradrenaline, and will cause dilation of normal pupil, but not one with loss of sympathetic innervation (Horner's Syndrome)
  - see Neurology, Figure 8, N6

Pupillary Light Reflex

- light shone directly into eye travels along optic nerve (CN II, afferent limb) → optic tracts → bilateral midbrain
- impulses enter bilaterally in midbrain via prepectal area and Edinger-Westphal nuclei
- nerve impulses then travel down CN III (efferent limb) bilaterally to reach the ciliary ganglia, and finally to the iris sphincter muscle, which results in the direct and consensual light reflexes

Pupil Abnormalities

Denervation Hypersensitivity

- when post-ganglionic fibers are damaged, the understimulated end-organ develops an excess of neuroreceptors and becomes hypersensitive
- postganglionic parasympathetic lesions (i.e. Adie's pupil)
  - pupil will constrict with 0.125% pilocarpine (cholinergic agonist), normal pupil will not
- postganglionic sympathetic lesions (this test is used to differentiate between pre- and post-ganglionic lesions in Horner's syndrome)
  - pupil will dilate with 0.125% adrenaline, normal pupil will not

Local Disorders of Iris

- posterior synechiae (adhesions between iris and lens) due to iritis can present as an abnormally shaped pupil
- ischemic damage (e.g. post-acute angle-closure glaucoma) usually occurs at 3 and 9 o'clock positions resulting in a vertically oval pupil that reacts poorly to light
- trauma (e.g. post-intraocular surgery)

Anisocoria

- unequal pupil size
- idiopathic/physiologic anisocoria
  - 20% of population
  - round, regular, <1 mm difference
  - pupils reactive to light and accommodation
  - responds normally to mydriatics/miotics
- post eye surgery
- see Table 7 for other causes of anisocoria

5 Targets of Retinal Signals

- Pre-tectal nucleus (pupillary reflex/eye movements)
- Lateral geniculate body of thalamus
- Superior colliculus (eye movements)
- Suprachiasmatic nucleus (optokinetic)
- Accessory optic system (circadian rhythm)

Patient with Anisocoria

Relevant history and examination with specific attention to:
- History of ocular trauma
- Check old photographs (ptosis, ocular deviation, long standing anisocoria)
- Use of topical medications
- Exposure to toxins and drugs
- Associated ocular and neurologic symptoms/signs

Which pupil is abnormal? Examine pupils in light and dark

Anisocoria accentuated by darkness (small pupil abnormal)
- Dilation lag
- Ptosis
- Test with 10% cocaine
- Small pupil does not dilate
- Horner’s syndrome

Anisocoria equal in light and dark
- Brisk reaction to light
- Use of 0.1% pilocarpine
- Both pupils dilate symmetrically

Anisocoria accentuated by light (large pupil is abnormal)
- Isolated Sluggish to light
- Light near dissociation
- Large pupil constricts
- Use of 0.1% pilocarpine
- Adie’s tonic pupil
- Minimal/no constriction

Pupil must fixate on distant target
**Dilated Pupil (Mydriasis)**

**Sympathetic Stimulation**
- fight or flight response
- mydriatic drugs: epinephrine, dipivefrin (Propine®), phenylephrine

**Parasympathetic Understimulation**
- cycloplegics/mydriatics: atropine, tropicamide, cyclopentolate (parasympatholytic)
- CN III palsy
  - eye deviated down and out with ptosis present
  - etiology includes stroke, neoplasm, aneurysm, acute rise in ICP, DM (may spare pupil), trauma
- CN III palsy will respond to drugs (e.g. pilocarpine), unlike a pupil dilated from medication (mydriatics)

**Parasympathetic Stimulation**
- local or systemic medications such as:
  - cholinergic agents: pilocarpine, carbachol
  - cholinesterase inhibitor: phospholine iodide
  - opiates, barbiturates

**Adie’s Tonic Pupil**
- 80% unilateral, F>M
- pupil is tonic or reacts poorly to light (both direct and consensual) but constricts with accommodation
- if decreased deep tendon reflexes may be Adie’s syndrome
- caused by benign lesion in ciliary ganglion; results in denervation hypersensitivity of parasympathetically innervated constrictor muscle
  - dilute (0.125%) solution of pilocarpine will constrict tonic pupil but have no effect on normal pupil
- long-standing Adie’s pupils are smaller than unaffected eye

**Trauma**
- damage to iris sphincter from blunt or penetrating trauma
- iris transillumination defects may be apparent using ophthalmoscope or slit-lamp
- pupil may be dilated (traumatic mydriasis) or irregularly shaped from tiny sphincter ruptures

**Constricted Pupil (Miosis)**

**Senile Miosis**
- decreased sympathetic stimulation with age

**Parasympathetic Stimulation**
- central or systemic medications such as:
  - cholinergic agents: pilocarpine, carbachol
  - cholinesterase inhibitor: phospholine iodide
  - opiates, barbiturates

**Horner’s Syndrome**
- lesion in sympathetic pathway
- difference in pupil size greater in dim light, due to decreased innervation of adrenergics to iris dilator muscle
- associated with ptosis, anhidrosis of ipsilateral face/neck
- application of cocaine 4-10% (blocks reuptake of noradrenaline) to eye does not result in pupil dilation (vs. physiologic anisocoria), therefore confirms diagnosis
- hydroxyamphetamine 1% (stimulates noradrenaline release) will dilate pupil if central or preganglionic lesion, not postganglionic lesion
- postganglionic lesions result in denervation hypersensitivity, which will cause pupil to dilate with 0.125% adrenaline, whereas normal pupil will not
- causes: carotid or subclavian aneurysm, brainstem infarct, demyelinating disease, cervical or mediastinal tumor, Pancoast tumor, goiter, cervical lymphadenopathy, surgical sympathectomy, Lyme disease, cervical ribs, tabs dorsalis, cervical vertebral fractures

**Iritis**
- miotic pupil initially
- later, may be irregularly shaped pupil due to posterior synchiae
- later stages non-reactive to light
Argyll-Robertson Pupil
- both pupils irregular and <3 mm in diameter, ± ptosis
- does not respond to light stimulation
- responds to accommodation (light-near dissociation)
- suggestive of neurosyphilis or other conditions (DM, encephalitis, MS, chronic alcoholism, CNS degenerative diseases)

Other Causes
- optic neuritis, retinal lesions

Relative Afferent Pupillary Defect

- also known as Marcus Gunn pupil
- impairment of direct pupillary response to light, caused by a lesion in visual afferent (sensory) pathway anterior to optic chiasm
- differential diagnosis: large RD, BRAO, CRAO, CRVO, advanced glaucoma, optic nerve compression, optic neuritis (most common)
- does not occur with media opacity (e.g. corneal edema, cataracts)
- pupil reacts poorly to light and better to accommodation
- test: swinging flashlight
  - if light is shone in the affected eye, direct and consensual response to light is decreased
  - if light is shone in the unaffected eye, direct and consensual response to light is normal
- if the light is moved quickly from the unaffected eye to the affected eye, “paradoxical” dilation of both pupils occurs
  - observe red reflex, especially in patients with dark irides
- if the defect is bilateral there is no RAPD, as dilation is measured relative to the other eye
Malignancies

- uncommon site for 1° malignancies
- eye usually affected secondarily by cancer or cancer treatments
- see Retinoblastoma, OP41

Lid Carcinoma

Etiology
- basal cell carcinoma (rodent ulcer) (90%)
  - spread via local invasion, rarely metastasizes
  - ulcerated center, indurated base with pearly rolled edges, telangiectasia
- squamous cell carcinoma (<5%)
  - spread via local invasion, may also spread to nodes and metastasize
  - ulceration, keratosis of lesion
- sebaceous cell carcinoma (1-5%)
  - often masquerades as chronic blepharitis or recurrent chalazion
  - highly invasive, metastasize
- Kaposi’s sarcoma, malignant melanoma, Merkel cell tumor, metastatic tumor

Treatment
- incisional or excisional biopsies
- may require cryotherapy, radiotherapy, chemotherapy, immunotherapy
- surgical reconstruction

Malignant Melanoma

- most common 1° intraocular malignancy in adults
- more prevalent in Caucasians
- arise from uveal tract, 90% choroidal melanoma
- hepatic metastases predominate

Treatment
- imaging to investigate spread
- depending on the size of the tumor, either radiotherapy, enucleation, limited surgery

Metastases

- most common intraocular malignancy in adults
- most commonly from breast and lung in adults, neuroblastoma in children
- usually infiltrate the choroid, but may also affect the optic nerve or extraocular muscles
- may present with decreased or distorted vision, irregularly shaped pupil, iritis, hyphema

Treatment
- local radiation, chemotherapy
- enucleation if blind, painful eye

Ocular Manifestations of Systemic Disease

HIV/AIDS

- up to 75% of patients with AIDS have ocular manifestations

External Ocular Signs
- Kaposi’s sarcoma
  - secondary to human herpes virus 8 (HHV-8), affects conjunctiva of lid or globe
  - numerous vascular skin malignancies
- differential diagnosis: subconjunctival hemorrhage (non-clearing), hemangioma
- multiple molluscum contagiosum
- herpes simplex keratitis
- herpes zoster keratitis
Retina
- HIV retinopathy (most common)
  - cotton wool spots in >50% of HIV patients
  - intraretinal hemorrhage
- CMV retinitis
  - ocular opportunistic infection that develops in late stages of HIV when severely immunocompromised (CD4 count ≤50)
  - a necrotizing retinitis, with retinal hemorrhage and vasculitis, "brushfire" or "pizza pie" appearance
  - presents with scotomas (macular involvement and RD, blurred vision, and floaters)
  - untreated infection will progress to other eye in 4-6 wk
  - treatment: virostatic agents (e.g. gancyclovir or foscarnet) via IV or intravitreal injection
- necrotizing retinitis
  - from herpes simplex virus, herpes zoster, toxoplasmosis
- disseminated choroiditis
  - *Pneumocystis carinii, Mycobacterium avium intracellulare, Candida*

Other Systemic Infections
- herpes zoster
  - see Herpes Zoster, OP19
- candidal endophthalmitis
  - fluffy, white-yellow, superficial retinal infiltrate that may eventually result in vitritis
  - may present with inflammation of the anterior chamber
  - treatment: systemic amphotericin B, oral fluconazole
- toxoplasmosis
  - focal, gray-yellow-white, chorioretinal lesions with surrounding vasculitis and vitreous infiltration (vitreous cells)
  - can be congenital (transplacental) or acquired (caused by *Toxoplasma gondii* protozoa transmitted through raw meat and cat feces)
  - congenital form more often causes visual impairment (more likely to involve the macula)
  - treatment: pyrimethamine, sulfonamide, folinic acid, or clindamycin. Consider adding steroids if severe inflammation (vitritis, macular or optic nerve involvement)

Diabetes Mellitus
- see Endocrinology, E6
- most common cause of blindness in young people in North America
- consider DM if unexplained retinopathy, cataract, extraocular muscle palsy, optic neuropathy, sudden change in refractive error
- loss of vision due to
  - progressive microangiopathy leading to macular edema
  - progressive DR → neovascularization → traction → RD and vitreous hemorrhage
  - retinal ischemia (neovascularization of the retina) leading to neovascular glaucoma (poor prognosis)
  - macular ischemia

DIABETIC RETINOPATHY

Background
- altered vascular permeability (loss of pericytes, breakdown of blood-retinal barrier, thickening of basement membrane)
- predisposition to retinal vessel obstruction (CRAO, CRVO, and BRVO)

Classification
- non-proliferative: increased vascular permeability and retinal ischemia
  - microaneurysms
  - dot and blot hemorrhages
  - hard exudates (lipid deposits), non-specific for DR
  - macular edema
- advanced non-proliferative (or pre-proliferative)
  - non-proliferative findings plus
    - venous beading (in ≥2 of 4 retinal quadrants)
    - intraretinal microvascular anomalies (IRMA) in 1 of 4 retinal quadrants
      - IRMA: dilated, leaky vessels within the retina
      - cotton wool spots (nerve fiber layer infarcts)
- proliferative
  - 5% of patients with DM will reach this stage
- neovascularization of iris, disc, retina to vitreous
- neovascularization of iris (rubeosis iridis) can lead to neovascular glaucoma
- vitreous hemorrhage from bleeding, fragile new vessels, fibrous tissue can contract causing tractional RD
- high risk of severe visual loss secondary to vitreous hemorrhage, RD

Screening Guidelines for Diabetic Retinopathy
- type 1 DM
  - screen for retinopathy beginning annually 5 yr after disease onset
  - annual screening indicated for all patients over 12 yr and/or entering puberty
- type 2 DM
  - initial examination at time of diagnosis, then annually
- pregnancy
  - oculax exam in 1st trimester, close follow-up throughout as pregnancy can exacerbate DR
  - gestational diabetics are not at risk for DR

Treatment
- Diabetic Control and Complications Trial (DCCT)
  - tight control of blood sugar decreases frequency and severity of microvascular complications
- blood pressure control
- focal laser for clinically significant macular edema, intravitreal injection of corticosteroid or anti-VEGF for foveal involved diabetic macular edema
- panretinal laser photocoagulation for PDR: reduces neovascularization, hence reducing the angiogenic stimulus from ischemic retina by decreasing retinal metabolic demand → reduces risk of blindness
- vitreectomy for non-clearing vitreous hemorrhage and RD in PDR
- vitrectomy before vitreous hemorrhage does not improve the visual prognosis

Lens Changes
- earlier onset of senile nuclear sclerosis and cortical cataract
- may get hyperglycemic cataract, due to sorbitol accumulation (rare)
- earlier onset of senile nuclear sclerosis and cortical cataract
- changes in blood glucose levels (poor control) can suddenly cause refractive changes by 3-4 diopters

Extraocular Muscle Palsy
- usually CN III infarct
- pupil usually spared in diabetic CN III palsy, but ptosis is observed
- may involve CN IV and VI
- usually recover within few months

Optic Neuropathy
- visual acuity loss due to infarction of optic disc/nerve

**Figure 25. DM vs. HTN retinopathy**

Clinically significant macular edema is defined as thickening of the retina at or within 500 µm of the center of the macula

Effects of Medical Therapies on Retinopathy
**Progression in Type 2 DM**

*NEJM* 2010;362:233-244

**Purpose:** To determine whether or not intensive glycemic control, combination therapy for dyslipidemia, and intensive blood-pressure control may limit the progression of DR in persons with type 2 DM.

**Methods:** RCT with 10,251 participants with type 2 DM at high risk of cardiovascular disease. Intensive or standard treatment for glycaemia (glycated hemoglobin level < 6.0% or 7.0-7.9%), dyslipidemia (180 mg daily fenofibrate plus simvastatin or placebo plus simvastatin), or systolic blood-pressure control (target <120 or <140 mm Hg).

**Results:** Rates of progression of DR at 4 yr were 7.3% with intensive glycaemia treatment vs. 10.4% with standard therapy (OR 0.67; 95% CI 0.51-0.87); 6.5% with fenofibrate for intensive dyslipidemia therapy vs. 10.2% with placebo (OR 0.60; 95% CI 0.42-0.87) and 10.4% with intensive blood-pressure therapy vs. 8.8% with standard therapy (OR 1.23; 95% CI 0.94-1.59).

**Conclusions:** Intensive glycemic control and intensive combination treatment of dyslipidemia, but not intensive blood-pressure control, reduced the rate of DR.

Early Treatment Diabetic Retinopathy Study

**Study:** Randomized clinical trial.

**Objective:** To evaluate argon laser photocoagulation and aspirin treatment in the management of patients with nonproliferative or early PDR.

**Patients:** Men and women between the ages of 18 and 70 yr with moderate or severe nonproliferative DR or mild PDR in both eyes, with no previous photocoagulation treatment, and with visual acuity of 20/40 or better (20/200 or better if macular edema is present) were eligible for this study.

**Intervention:** All study patients had one eye randomly assigned to immediate photocoagulation and the other eye to deferral of photocoagulation until high-risk proliferative retinopathy developed. The trial use of aspirin therapy was based on clinical observation and on aspirin's possible mechanisms of action.

**Results:** A total of 3,711 patients were recruited to follow a minimum of 4 yr to provide long-term information on the risks and benefits of the treatments under study. The study demonstrated that focal photocoagulation for macular edema reduces the risk of moderate visual loss and should be considered for eyes with clinically significant macular edema. Scatter photocoagulation reduces the risk of severe visual loss. The ETDRS does not support scatter treatment before the severe nonproliferative stage of DR. Aspirin treatment (850 mg/day) does not alter progression of DR.

**Conclusion:** Before current treatments, the prognosis for patients with PDR was blindness within 5 yr for >50% of patients. Rates of blindness in ETDRS patients following the development of proliferative retinopathy are remarkably lower.
Hypertension

- retinopathy is the most common ocular manifestation
- chronic HTN retinopathy: arteriovenous (AV) nicking, blot retinal hemorrhages, microaneurysms, cotton wool spots
- acute HTN retinopathy: retinal arteriolar spasm, superficial retinal hemorrhage, cotton wool spots, optic disc edema

</tbody>
</table>
| Group 4       | Group 3 plus papilledema  

Multiple Sclerosis

- see Neurology, N52

Clinical Features

- blurred vision and decreased color vision: secondary to optic neuritis
- central scotoma: due to damage to papillomacular bundle of retinal nerve fibers
- diplopia: secondary to INO
- RAPD, ptosis, nystagmus, uveitis, optic atrophy, optic neuritis
- white matter demyelinating lesions of optic nerve on MRI

Treatment

- IV steroids with taper to oral form for optic neuritis
- DO NOT treat with oral steroids in isolation as this increases likelihood of eventual development of MS

TIA/Amaurosis Fugax

- sudden, transient blindness from intermittent vascular compromise
- ipsilateral carotid most frequent embolic source
- typically monocular, lasting <5-10 min
- Hollenhorst plaques (glistening microemboli seen at branch points of retinal arterioles)

Graves’ Disease

- ophthalmopathy occurs despite control of thyroid gland status
- ocular manifestations occur secondary to sympathetic overdrive and/or specific inflammatory infiltrate of the orbital tissue

Clinical

- initial inflammatory phase is followed by a quiescent cicatricial phase

Treatment

- treat hyperthyroidism
- monitor for corneal exposure and maintain corneal hydration
- manage diplopia, ptosis and compressive optic neuropathy with one or a combination of:
  - steroids (during acute phase)
  - orbital bony decompression
  - external beam radiation of the orbit
- consider strabismus and/or eyelid surgical procedures once acute phase subsides

Connective Tissue Disorders

- RA, juvenile idiopathic arthritis, SLE, Sjögren syndrome, ankylosing spondylitis, polyarteritis nodosa
- most common ocular manifestation: dry eyes (keratoconjunctivitis sicca)
**Giant Cell Arteritis/Temporal Arteritis**

- see [Rheumatology, R17](R17)

**Clinical**
- more common in women >60 yr
- abrupt monocular loss of vision, pain over the temporal artery, jaw claudication, scalp tenderness, constitutional symptoms, and past medical history of polymyalgia rheumatica
- ischemic optic atrophy
  - 50% lose vision in other eye if untreated

**Diagnosis**
- temporal artery biopsy + increased ESR (ESR can be normal, but likely 80-100 in first hour), CRP
- if biopsy of one side is negative, biopsy the other side

**Treatment**
- high dose corticosteroid to relieve pain and prevent further ischemic episodes
- if diagnosis of GCA is suspected clinically: start treatment + perform temporal artery biopsy to confirm diagnosis within 2 wk of initial presentation (DO NOT WAIT TO TREAT)

**Sarcoidosis**
- granulomatous uveitis with large “mutton fat” keratic precipitates and posterior synechiae
- neurosarcoidosis: optic neuropathy, oculomotor abnormalities, visual field loss

**Treatment**
- steroids and mydriatics

**Pediatric Ophthalmology**

**Strabismus**
- ocular misalignment in one or both eyes, found in 3% of children
- object not visualized simultaneously by fovea of each eye
- terms used to describe strabismus depend upon
  - direction of deviation relative to the fixating eye
  - conditions under which it presents: 'latent', 'manifest' misalignment
  - change with the position of gaze: 'comitant' (usually nonparalytic), 'incomitant' (usually occurs with paralytic or restrictive strabismus)
- often presents with parental concern about a wandering eye, crossing eye, or poor vision
- elicit a detailed family history of strabismus, amblyopia, type of eyeglasses and history of wear, extraocular muscle surgery or other eye surgery, and genetic diseases to identify children at higher risk
- distinguish from pseudostrabismus (prominent epicanthal folds, hypertelorism, markedly positive or negative angle $\kappa$)
- complications: amblyopia, cosmesis

**HETEROTROPIA**
- manifest deviation
- deviation not corrected by the fusion mechanism (i.e. deviation is apparent when the patient is using both eyes)

**Types**
- exo- (lateral deviation), eso- (medial deviation)
- hyper- (upward deviation), hypo- (downward deviation)
- esotropia = "crossed-eyes", exotropia = "wall-eyed"

**Differentiate from Pseudostrabismus**
- prominent epicanthal folds: give appearance of esotropia but Hirschberg test is normal, more common in Asians
- markedly elevated angle $\kappa$ (the angle formed by the pupillary axis and the visual axis at the center of the pupil)
  - caused by the failure of optical axis of the eye and visual axis to coincide
  - a small positive (up to 5°) angle $\kappa$ is physiologic
  - a large positive angle $\kappa$ (nasally deviated fovea) simulates eso-appearance
  - a large negative angle $\kappa$ (temporally deviated fovea) gives an exo-appearance
Tests
- Hirschberg test (corneal light reflex): positive if the light reflex on both corneas is asymmetrical
  - light reflex lateral to central cornea indicates esodeviation; light reflex medial to central cornea indicates exodeviation
  - false positives occur if visual axis and anatomic pupillary axis of the eye are not aligned (angle $\kappa$)
- cover test
- the deviation can be quantified using prisms

HETEROPHORIA
- latent deviation
  - deviation corrected in the binocular state by the fusion mechanism (i.e. deviation not seen when patient is focusing with both eyes)
  - Hirschberg test will be normal (light reflexes symmetrical)
  - very common – majority are asymptomatic
- may be exacerbated or become manifest with asthenopia (eye strain, fatigue)

Tests
- cover-uncover test
- alternate cover test
  - alternating the cover between both eyes reveals the total deviation, both latent and manifest
  - maintain cover over one eye for 2-3 s before rapidly shifting to other eye

Table 9. Paralytic vs. Non-Paralytic Strabismus

<table>
<thead>
<tr>
<th>Clinical Characteristics</th>
<th>Paralytic Strabismus</th>

</thead>
<tbody>
<tr>
<td>Definition</td>
<td>Incomitant strabismus</td>
<td>Concomitant strabismus</td>
</tr>
<tr>
<td>Onset</td>
<td>Often sudden but may be gradual or congenital</td>
<td>Usually gradual or shortly after birth; rarely sudden</td>
</tr>
<tr>
<td>Age of Onset</td>
<td>Any age; most often acquired</td>
<td>Usually during infancy</td>
</tr>
</tbody>
</table>
| Etiology                 | Reduction or restriction in range of eye movements due to:
  - Neural (CN III, IV, VI): ischemia (e.g. DM), MS, aneurysm, brain tumor, trauma
  - Muscular: myasthenia gravis (neuromuscular junction pathology), Graves’ disease
  - Structural: restriction or entrapment of extraocular muscles due to orbital inflammation, tumor, fracture of the orbital wall | Develops early in childhood
| Diplopia                 | Common | Uncommon; image from the misaligned eye is suppressed (see Amblyopia, OP40) |
| Visual Acuity in Other Eye | Usually unaffected in the other eye, unless CN II is involved | Deviated eye may become amblyopic if not treated when the child is young
  Amblyopia usually does not develop if child has alternating strabismus or intermittency, which allows neural pathways for both eyes to develop |
| Possibility of Amblyopia | Uncommon | Common |
| Neurologic Findings or Systemic Disease | May be present | Usually absent |
Accommodative Esotropia
- normal response to approaching object is the triad of the near reflex: convergence, accommodation and miosis
- hyperopes must constantly accommodate – excessive accommodation can lead to esotropia in young children via over-activation of the near reflex
- average age of onset is 2.5 yr
- usually reversible with correction of refractive error

Non-accommodative Esotropia
- accounts for 50% of childhood strabismus
- most are idiopathic
- may be due to monocular visual impairment (e.g. cataract, corneal scarring, anisometropia, retinoblastoma) or divergence insufficiency (ocular misalignment that is greater at distance fixation than at near fixation)

Amblyopia

Definition
- a neurodevelopmental visual disorder with unilateral (or less commonly, bilateral) reduction of best corrected visual acuity that cannot be attributed only and directly to the effect of a structural abnormality of the eye. It is caused by abnormal visual experience early in life and cannot be remedied immediately by spectacle glasses alone
- in approximately half of the cases, amblyopia is secondary to strabismus (mainly esotropia), Other causes may include uncorrected refractive errors, anisometropia (asymmetric refractive errors), and concomitant structural ocular problems

Detection
- "Holler Test": young child upset if good eye is covered
- quantitative visual acuity by age 3-4 yr using picture charts and/or matching game (Sheridan-Gardiner), testing each eye separately
- amblyopia treatment less successful after age 8-10 yr, but a trial should be given no matter what age
- prognosis: 90% will have good vision restored and maintained if treated <4 yr old

Etiology and Management
- strabismus
  - correct with glasses for accommodative esotropia (50% of children experience relief of their esotropia with glasses and will not require surgery)
  - occlusion of unaffected eye forces brain to use previously strabismic eye; aims to bring vision in previously suppressed eye to normal before surgery
  - surgery: recession (weakening) – moving muscle insertion further back on the globe; or resection (strengthening) – shortening the muscle
  - botulinum toxin for single muscle weakening
  - after ocular alignment is restored (glasses, surgery, botulinum toxin), patching is frequently necessary to maintain vision until approximately age 8 yr
- anisometropia
  - amblyopia usually in the more hyperopic eye
  - the more emmetropic (normal refraction) eye receives a clear image while the less emmetropic eye receives a blurred image; input from the blurred eye is cortically suppressed and visual pathway fails to develop normally
  - treat with glasses to correct refractive error
  - patching is required if visual acuity difference persists after 4-8 wk of using glasses
- deprivation amblyopia
  - occlusion due to ptosis, cataract, retinoblastoma, corneal opacity
  - occlusion amblyopia: prolonged patching of good eye may cause it to become amblyopic

Occlusion Therapy
- patching the good eye to force the brain to use the non-dominant eye and redevelop its vision
- atropine cycloplegic drops to impair accommodation and blur vision of the better seeing eye

Risks
- permanent loss of vision in the affected eye
- possibility of injury to ‘remaining’ good eye
  - safety glasses or polycarbonate lenses recommended if visual acuity in worse eye is <20/50
- loss of stereopsis
Leukocoria

- white reflex (red reflex is absent)

Differential Diagnosis
- cataract
- retinoblastoma
- retinal coloboma
- ROP
- persistent hyperplastic primary vitreous
- Coats’ disease (exudative retinal telangiectasis)
- toxocariasis
- RD

Retinoblastoma

- most common primary intraocular malignancy in children
- incidence: 1/15,000; sporadic or genetic transmission; screening of siblings/offspring essential
- unilateral or bilateral (in 1/3 of cases)
- malignant – direct or hematogenous spread
- diagnosis
  - often presents with leukocoria or strabismus
  - U/S or CT scan may demonstrate calcified mass (present in most cases)

Treatment
- radiotherapy, chemotherapy combined with laser, cryopexy, and/or enucleation

Retinopathy of Prematurity

- vasoproliferative retinopathy that is a major cause of blindness in the developed world

Risk Factors
- non-black race (black infants have lower risk of developing ROP)
- low gestational age, birth weight <1500 g
- high oxygen exposure after birth

Classification (ROP Staging)
- stage 1: faint demarcation line at the junction between the vascularized and avascular retina
- stage 2: elevated ridge
- stage 3: extra-retinal fibrovascular tissue extending into vitreous
- stage 4: partial RD (4A: macula “on”, 4B: macula “off”)
- stage 5: total RD
- plus (+) disease: dilatation and tortuosity of retinal vessels
- threshold disease: stage 3+ in zones 1 or 2 with 5 continuous or 8 cumulative clock hours of ROP involvement

Treatment
- threshold disease is treated with cryotherapy or laser (laser is now the standard treatment, with better refractive outcome), off label anti-VEGF intravitreal injections
- ROP beyond threshold level is either watched carefully (usually stage 4A) or treated with vitrectomy/scleral buckle

Prognosis
- higher incidence of myopia among ROP infants, even if treated successfully
- stage 4B and 5 have poor prognosis for visual outcome despite treatment

Nasolacrimal System Defects

- congenital obstruction of the nasolacrimal duct (failure of canalization), usually occurs at 1–2 mo of age
- epiphora, crusting, discharge, recurrent conjunctivitis
- can have reflux of mucopurulent material from lacrimal punctum when pressure is applied over lacrimal sac
- treatment: massage over lacrimal sac at medial corner of eyelid
- vast majority spontaneously resolve in 9–12 mo, otherwise consider referral for duct probing

Efficacy of Intravitreal Bevacizumab for Stage 3+ Retinopathy of Prematurity (ROP)

- Study: Randomized controlled clinical trial.
- Patients: 150 infants born at gestational age ≤30 wk and birth weight ≤1500 g.
- Intervention: Randomized to conventional laser therapy or intravitreal bevacizumab monotherapy.
- Main Outcome: Recurrence of ROP in one or both eyes requiring retreatment before 54 wk postmenstrual age.
- Results: ROP recurrence was lower in the bevacizumab group (8 of 140 eyes [6%]) vs. the laser-therapy group (32 of 146 eyes [22%]) (p = 0.002). A significant treatment effect was found for zone I ROP (p = 0.003).
- Conclusions: Intravitreal bevacizumab monotherapy is beneficial for infants with zone I stage 3+ ROP and allows continued development of peripheral retinal vessels following treatment.
Ophthalmia Neonatorum

- newborn conjunctivitis in first month of life
- causes
  - toxic: silver nitrate, erythromycin
  - infectious: bacterial (e.g. *N. gonorrhoeae* – most common, *C. trachomatis*), herpes simplex virus
- diagnose using stains and cultures
- treatment: systemic antibiotics with possible hospitalization if infectious etiology
- topical prophylaxis, most commonly with erythromycin (or silver nitrate), is required by law at birth

Congenital Glaucoma

- due to inadequate development of the filtering mechanism of the anterior chamber angle

Clinical Features

- cloudy cornea, increased IOP
- photophobia, epiphora
- buphthalmos (large cornea, "ox eye", secondary to increased IOP), blepharospasm

Treatment

- filtration surgery is required soon after birth to prevent blindness

Ocular Trauma

Blunt Trauma

- caused by blunt object such as fist, squash ball
- history: injury, ocular history, drug allergy, tetanus status
- exam: VA first, pupil size and reaction, EOM (diplopia), external and slit-lamp exam, ophthalmoscopy
- if VA normal or slightly reduced, globe less likely to be perforated
- if VA reduced may be perforated globe, corneal abrasion, lens dislocation, retinal tear
- bone fractures
  - blow out fracture: restricted EOM, diplopia, enophthalmos (sunken eye)
  - ethmoid fracture: subcutaneous emphysema of lid
- lids: swelling, laceration, emphysema
- conjunctiva: subconjunctival hemorrhage
- cornea: abrasion – detect with fluorescein staining and cobalt blue filter using slit-lamp or ophthalmoscope
- anterior chamber: assess depth, hyphema, hypopyon
- iris: prolapse, iritis
- lens: cataract, dislocation
- retinal tear/detachment

Penetrating Trauma

- include ruptured globe ± prolapsed iris, intraocular foreign body
- rule out intraocular foreign body, especially if history of "metal striking metal", orbit CT
- **OCULAR EMERGENCY**: initial management - REFER IMMEDIATELY
  - ABCs
  - don’t press on eye globe!
  - don’t check IOP if possibility of globe rupture
  - check vision, diplopia
  - apply rigid eye shield to minimize further trauma
  - keep head elevated 30-45° to keep IOP down
  - keep NPO
  - tetanus status
  - give IV antibiotics
  - selecting appropriate agents depends on the mechanism of injury; gram positive bacteria are more commonly involved than gram negatives; retained intraocular foreign objects increase the risk of infections with Bacillus species, whereas exposure to vegetable matter increased the risk of a fungal etiology

Post-Traumatic Infectious Endophthalmitis

Surv Ophthalmol 2011;56:214-251

- Delayed primary repair (> 24 h after open globe injury) increases risk for post-traumatic endophthalmitis in the absence of an intraocular foreign body (IOFB).
- If IOFB present, early vitrectomy and IOFB removal must be performed within 24 h of injury.
- Extreme pain with hypopyon and vitritis indicate endophthalmitis until proven otherwise, and samples must be obtained.
- Treat with empirical intravitreal and intravenous antibiotic guided by nature of trauma, and adjust based on culture.
**Hyphema**

- Blood in anterior chamber often due to damage to root of the iris
- May occur with blunt trauma

**Treatment**
- Refer to ophthalmology
  - Shield and bedrest x 5 d or as determined by ophthalmologist
  - Sleep with head upright
- May need surgical drainage if hyphema persists or if re-bleed

**Complications**
- Risk of re-bleed highest on days 2-5, resulting in secondary glaucoma, corneal staining, and iris necrosis
- Never prescribe Aspirin®, as it increases the risk of a re-bleed

---

**Blow-Out Fracture**

- See Plastic Surgery, PL31
- Blunt trauma causing fracture of orbital floor and herniation of orbital contents into maxillary sinus
- Orbital rim remains intact
- Inferior rectus and/or inferior oblique muscles may be incarcerated at fracture site
- Infraorbital nerve courses along the floor of the orbit and may be damaged

**Clinical Features**
- Pain and nausea at time of injury
- Diplopia, restriction of EOM
- Infraorbital and upper lip paresthesia (CN V2)
- Enophthalmos (sunken eye), periorbital ecchymoses

**Investigations**
- Plain films: Waters' view and lateral
- CT: Anteroposterior and coronal view of orbits

**Treatment**
- Refrain from coughing, blowing nose
- Systemic antibiotics may be indicated
- Surgery if fracture >50% orbital floor, diplopia not improving, or enophthalmos >2 mm
- May delay surgery if the diplopia improves

---

**Chemical Burns**

- Alkali burns have a worse prognosis than acid burns because acids coagulate tissue and inhibit further corneal penetration
- Poor prognosis if cornea opaque, likely irreversible stromal damage
- Even with a clear cornea initially, alkali burns can progress for weeks (thus, very guarded prognosis)

**Treatment**
- Immediately irrigate at site of accident with water or buffered solution
  - IV drip for at least 20-30 min with eyelids retracted in emergency department
  - Swab upper and lower fornices to remove possible particulate matter
- Do not attempt to neutralize because the heat produced by the reaction will damage the cornea
- Cycloplegic drops to decrease iris spasm (pain) and prevent secondary glaucoma (due to posterior synechiae formation)
- Topical antibiotics and patching
- Topical steroids (by ophthalmologist) to decrease inflammation, use for <2 wk (in the case of a persistent epithelial defect)
Surgical Ophthalmology

- dacr,
  cystorhinostomy (DCR): excision of bone covering the nasolacrimal sac to restore tear drainage
- LASIK (laser-assisted in situ keratomileusis): a microkeratome is used to create a corneal flap followed by laser remodeling of the stroma to correct refractive error
- trabeculectomy: creation of a new outflow tract from anterior chamber to under conjunctiva; fibrosis prevented with mitomycin C or 5-FU injection during surgery
- phacoemulsification (cataract extraction): the use of ultrasonic waves to break up and aspirate a cataract followed by replacement with an artificial lens implant
- femtosecond laser-assisted cataract surgery: uses focused ultrashort pulses (10^-15 of a second) to perform photodissection in achieving capsulorrhexis and lens fragmentation
- vitrectomy: the use of small gauge trochars to enter the posterior segment and remove vitreous; commonly used to treat vitreous hemorrhage and RD
- scleral buckle: a silicone band is secured on the outside of the globe that indents the eye wall, thereby relieving vitreous traction on the retina around any tears/holes and allowing the tears/holes to remain sealed for repair of RD
- minimally invasive glaucoma surgery (MIGS): implantation of IOP lowering drainage devices (e.g. iStent) through an ab interno microincisional approach during cataract surgery.

Common Medications

TOPICAL OCULAR DIAGNOSTIC DRUGS

Fluorescein Dye
- water soluble orange-yellow dye
- green under cobalt blue light (ophthalmoscope or slit-lamp)
- absorbed in areas of epithelial loss (ulcer or abrasion)
- also stains mucus and contact lenses
Rose Bengal Stain
• stains devitalized epithelial cells and mucus

Anesthetics
• e.g. proparacaine HCl 0.5%, tetracaine 0.5%
• indications: removal of foreign body and sutures, tonometry, examination of painful cornea
• toxic to corneal epithelium (inhibit mitosis and migration) and can lead to corneal ulceration and scarring with prolonged use, therefore NEVER prescribe

Mydriatics
• dilate pupils
• two classes
  ▪ cholinergic blocking (e.g. tropicamide – Mydriacyl®)
    • dilation plus cycloplegia (loss of accommodation) by paralysis of iris sphincter and the ciliary body
    • indications: refraction, ophthalmoscopy, therapy for iritis
  ▪ adrenergic stimulating (e.g. phenylephrine HCl 2.5%)
    • stimulate pupillary dilator muscles, no effect on accommodation
    • usually used with tropicamide for additive effects
    • side effects: HTN, tachycardia, arrhythmias

WET AGE-RELATED MACULAR DEGENERATION MEDICATIONS

VEGF Inhibitors
• block VEGF which prevents ocular angiogenesis and further development of choroidal neovascularization
• administered via intravitreal injections
• pegaptanib (Macugen®) is a selective anti-VEGF targeting VEGF isoform 165 (no longer widely used)
• ranibizumab (Lucentis®) is a non-selective anti-VEGF agent
• aflibercept (Eylea®) is an VEGF “trap” agent that binds VEGF-A and placental growth factor
• bevacizumab (Avastin®) is another non-selective anti-VEGF agent but is only FDA approved for metastatic breast cancer, colorectal cancer, and non-small cell lung cancer; therefore, its ophthalmologic use is off-label

TOPICAL OCULAR THERAPEUTIC DRUGS

NSAIDs
• used for less serious chronic inflammatory conditions
• e.g. ketorolac (Acaral®), diclofenac (Voltaren®), nepafenac (Nevanac®) drops

Anti-Histamines
• used to relieve red and itchy eye, often in combination with decongestants
• sodium cromoglycate – stabilizes membranes

Decongestants
• weak adrenergic stimulating drugs (vasoconstrictor)
• e.g. naphazoline, phenylephrine
• rebound vasodilation with overuse; rarely can precipitate angle closure glaucoma

Antibiotics
• indications: bacterial conjunctivitis, keratitis, or blepharitis
• commonly as topical drops or ointments, may give systemically
• e.g. sulfonamide (sodium sulfacetamide, sulfisoxazole), gentamicin (Garamycin®), erythromycin, tetracycline, bacitracin, polymyxin B, fluoroquinolones (ciprofloxacin [Ciloxan®], ofloxacin [Ocuflox®], moxifloxacin [Vigamox®], gatifloxacin [Zyman®])

Corticosteroids
• e.g. fluorometholone (FML®), betamethasone, dexamethasone (Maxidex®), prednisolone (Pred Forte® 1%), rimexolone (Voxel®), loteprednol etabonate 0.5% (Lotamax®)
• primary care physicians should avoid prescribing topical corticosteroids due to risk of glaucoma, cataracts, and reactivation of HSV keratitis
• complications
  ▪ potentiates HSV keratitis and fungal keratitis as well as masks symptoms
  ▪ increased IOP, more rapidly in steroid responders (within weeks)
  ▪ posterior subcapsular cataract (within months)

Figure 3. Nerves and arteries of lower limbs

Differential Diagnosis of Joint Pain

Joint Pain

Intrinsic
- Artricular
  - Arthritis, neoplasm, trauma
- Non-articular
  - Bursitis, tendonitis, myositis

Extrinsic
- Neurologic
  - Nerve root compression, HZV
- Generalized
  - Fibromyalgia, dermatomyositis
- Referred Pain
  - From nearby organs or tissue

Figure 4. Intrinsic vs. extrinsic joint pain
Fractures – General Principles

Fracture Description

1. Integrity of Skin/Soft Tissue
   • closed: skin/soft tissue over and near fracture is intact
   • open: skin/soft tissue over and near fracture is lacerated or abraded, fracture exposed to outside environment
     ▪ signs: continuous bleeding from puncture site or fat droplets in blood are suggestive of an open fracture

2. Location
   • epiphyseal: end of bone, forming part of the adjacent joint
   • metaphyseal: the flared portion of the bone at the ends of the shaft
   • diaphyseal: the shaft of a long bone (proximal, middle, distal)
   • physis: growth plate

3. Orientation/Fracture Pattern
   • transverse: fracture line perpendicular to long axis of bone; result of direct high energy force
   • oblique: angular fracture line; result of angular or rotational force
   • butterfly: fracture site fragment which looks like a butterfly
   • segmental: a separate segment of bone bordered by fracture lines; result of high energy force
   • spiral: complex, multi-planar fracture line; result of rotational force, low energy
   • comminuted/multi-fragmentary: >2 fracture fragments
   • intra-articular: fracture line crosses articular cartilage and enters joint
   • avulsion: tendon or ligament tears/pulls off bone fragment; often in children, high energy
   • compression/impacted: impaction of bone; typical sites are vertebrae or proximal tibia
   • torus: a buckle fracture of one cortex, often in children (see Figure 51, OR39)
   • greenstick: an incomplete fracture of one cortex, often in children (see Figure 51, OR39)
   • pathologic: fracture through bone weakened by disease/tumor

4. Displacement
   • nondisplaced: fracture fragments are in anatomic alignment
   • displaced: fracture fragments are not in anatomic alignment
   • distracted: fracture fragments are separated by a gap (opposite of impacted)
   • impacted: fracture fragments are compressed, resulting in shortened bone
   • angulated: direction of fracture apex, e.g. varus/valgus
   • translated/shifted: percentage of overlapping bone at fracture site
   • rotated: fracture fragment rotated about long axis of bone

Management of Fractures

• ABCs, primary survey and secondary survey (ATLS protocol)
  ▪ rule out other fractures/injuries
  ▪ rule out open fracture (see sidebar, OR6)
• AMPLE history: Allergies, Medications, Past medical history, Last meal, Events surrounding injury
  ▪ consider pathologic fracture with history of only minor trauma
• analgesia
• imaging
• splint extremity
1. obtain the reduction (for appropriate IV sedation see Table 28, OR47)
   - closed reduction
     - apply traction in the long axis of the limb
     - reverse the mechanism that produced the fracture
     - reduce with IV sedation and muscle relaxation (fluoroscopy can be used if available)
   - indications for open reduction
     - “NO CAST”
     - other indications include
       - not able to cast or apply traction due to site (e.g. hip fracture)
       - pathologic fractures
       - potential for improved function with ORIF
   - ALWAYS re-check NVS after reduction and obtain post-reduction x-ray

2. maintain the reduction
   - external stabilization: splints, casts, traction, external fixator
   - internal stabilization: percutaneous pinning, extramedullary fixation (screws, plates, wires), IM fixation (rods)
   - follow-up: evaluate bone healing

3. rehabilitate to regain function and avoid joint stiffness

## Fracture Healing

### Normal Healing

| Weeks 0-3 | Hematoma, macrophages surround fracture site |
| Weeks 3-6 | Osteoclasts remove sharp edges, callus forms within hematoma |
| Weeks 6-12 | Bone forms within the callus, bridging fragments |
| Months 6-12 | Cortical gap is bridged by bone |
| Years 1-2 | Normal architecture is achieved through remodelling |

### Evaluation of Healing: Tests of Union

- clinical: no longer tender to palpation or stressing on physical exam
- x-ray: trabeculae cross fracture site, visible callus bridging site on at least 3 of 4 cortices

## Articular Cartilage

### Properties

- 2-4 mm layer covering ends of articulating bones, provides nearly frictionless surface
- avascular (nutrition from synovial fluid), aenural, alymphatic
- composed of: collagen (90% is type II; gives tensile strength), water, proteoglycans (gives compressive strength), and chondrocytes
**ARTICULAR CARTILAGE DEFECTS**

**Etiology**
- overt trauma, repetitive minor trauma (such as patellar maltracking); common sports injury
- degenerative conditions such as early stage OA or osteochondritis dissecans

**Clinical Features**
- similar to symptoms of OA (joint line pain with possible effusion, etc.)
- often have predisposing factors, such as ligament injury, malalignment of the joint (varus/valgus), obesity, bone deficiency (AVN, osteochondritis dissecans, ganglion bone cysts), inflammatory arthropathy, and familial osteoarthropathy
- may have symptoms of locking or catching related to the torn/displaced cartilage

**Investigations**
- x-ray (to rule out bony defects and check alignment)
- MRI
- diagnostic arthroscopy (treatment is often guided by what is seen during arthroscopy)

**Table 3. Outerbridge Classification of Chondral Defects**

<table>
<thead>

</tr>
<tr>
<td>III</td>
<td>Fragmentation and fissuring &gt; 1/2&quot; in diameter</td>
</tr>
<tr>
<td>IV</td>
<td>Erosion of cartilage down to bone</td>
</tr>
</tbody>
</table>

**Treatment**
- individualized; must take into account patient factors (age, skeletal maturity, activity level, etc.) and defect factors (Outerbridge classification, subchondral bone involvement, etc.)
- non-operative: rest, NSAIDs, bracing
- operative: microfracture, osteochondral grafting (autograft or allograft), autologous chondrocyte implantation

### Orthopedic X-Ray Imaging

**General Principles**
- x-ray 1 joint above and 1 below
- obtain at least 2 orthogonal views ± specialized views

Orthopedic Emergencies

Trauma Patient Workup

Etiology
- high energy trauma, e.g. MVC, fall from height
- may be associated with spinal injuries or life-threatening visceral injuries

Clinical Presentation
- local swelling, tenderness, deformity of the limbs, and instability of the pelvis or spine
- decreased level of consciousness, hypotension/hypovolemia
- consider involvement of EtOH or other substances

Investigations
- trauma survey (see Emergency Medicine, ER5)
- x-rays: lateral cervical spine, AP chest, AP pelvis, AP and lateral of all bones suspected to be injured
- other views of pelvis: AP, inlet, and outlet; Judet views for acetabular fracture (for classification of pelvic fractures see Table 19, OR26)

Treatment
- ABCDEs and initiate resuscitation for life threatening injuries
- assess genitourinary injury (rectal exam/vaginal exam mandatory)
- external or internal fixation of all fractures
- DVT prophylaxis

Complications
- hemorrhage – life threatening (may produce signs and symptoms of hypovolemic shock)
- fat embolism syndrome (SOB, hypoxemia, petechial rash, thrombocytopenia, and neurological symptoms)
- venous thrombosis – DVT and PE
- bladder/urethral/bowel injury
- neurological damage
- persistent pain/stiffness/limp/weakness in affected extremities
- post-traumatic OA of joints with intra-articular fractures
- sepsis if missed open fracture

Open Fractures

Definition
- fractured bone and hematoma in communication with the external environment

Emergency Measures
- removal of obvious foreign material
- irrigate with normal saline if grossly contaminated

Buck’s Traction
A system of weights, pulleys, and ropes that are attached to the end of a patient’s bed exerting a longitudinal force on the distal end of a fracture, improving its length, alignment, and rotation

VON CHOP
Vascular compromise
Open fracture
Neurological compromise/cauda equina syndrome
Compartment syndrome
Hip dislocation
Osteomyelitis/septic arthritis
Unstable pelvic fracture

Antibiotics for Preventing Infection in Open Limb Fractures
Cochrane DB Syst Rev 2004;1:CD003764
Purpose: To review the evidence regarding the effectiveness of antibiotics in the initial treatment of open fractures of the limbs.
Methods: Randomized or quasi randomized controlled trials comparing antibiotic treatment with placebo or no treatment in preventing acute wound infection were identified and reviewed. Data were extracted and pooled for analysis.
Results: Eight studies (n=1,106) were reviewed. The use of antibiotics had a protective effect against early infection compared with no antibiotics or placebo (RRR=0.43, 95% CI 0.29, 0.65; ARR=0.07, 95% CI 0.03=0.10).
Conclusions: Antibiotics reduce the incidence of early infections in open fractures of the limbs.

33% of patients with open fractures have multiple injuries
• cover wound with sterile dressings
• immediate IV antibiotics
• tetanus toxoid or immunoglobulin as needed
• reduce and splint fracture
• NPO and prepare for OR (blood work, consent, ECG, CXR)
  • operative irrigation and debridement within 6-8 h to decrease risk of infection
  • traumatic wound often left open to drain but vacuum-assisted closure dressing may be used
  • re-examine with repeat I&D in 48 h

</tr>
<tr>
<td>II</td>
<td>1-10 cm</td>
<td>Moderate contamination Soft tissue injury</td>
<td>First generation cephalosporin (cefazolin) for 3 d plus Gram-negative coverage (gentamicin) for at least 3 d</td>
</tr>
<tr>
<td>III*</td>
<td>&gt;10 cm</td>
<td>IIIA: Extensive soft tissue injury with adequate ability of soft tissue to cover wound IIIB: Extensive soft tissue injury with periosteal stripping and bone exposure; inadequate soft tissue to cover wound IIIC: Vascular injury/compromise</td>
<td>As per Grade II For soil contamination, penicillin is added for clostridial coverage</td>
</tr>
</tbody>
</table>

*Any high energy, comminuted fracture, shot gun, farmyard/soil/water contamination, exposure to oral flora, or fracture >8 h old is immediately classified as Grade III

### Cauda Equina Syndrome

- see Neurosurgery, NS26

### Compartment Syndrome

#### Definition
- increased interstitial pressure in an anatomical compartment (forearm, calf) where muscle and tissue are bounded by fascia and bone (fibro-osseous compartment) with little room for expansion
- interstitial pressure exceeds capillary perfusion pressure leading to muscle necrosis (in 4-6 h) and eventually nerve necrosis

#### Etiology
- intracompartmental: fracture (particularly tibial shaft fractures, pediatric supracondylar fractures, and forearm fractures), crush injury, ischemia-reperfusion injury
- extracompartmental: constrictive dressing (circumferential cast, poor positioning during surgery), circumferential burn

#### Clinical Features
- pain with active contraction of compartment
- pain with passive stretch
- swollen, tense compartment
- suspicious history

- 5 Ps: late sign – do not wait for these to develop to make the diagnosis!
**Investigations**
- usually not necessary as compartment syndrome is a clinical diagnosis
- in children or unconscious patients where clinical exam is unreliable, compartment pressure monitoring with catheter AFTER clinical diagnosis is made (normal = 0 mmHg; elevated ≥30 mmHg or ≤30 mmHg of diastolic BP)

**Treatment**
- non-operative
  - remove constrictive dressings (casts, splints), elevate limb at the level of the heart
- operative
  - urgent fasciotomy
  - 48-72 h post-operative: wound closure ± necrotic tissue debridement

**Complications**
- rhabdomyolysis, renal failure secondary to myoglobinuria
- Volkmann's ischemic contracture: ischemic necrosis of muscle, followed by secondary fibrosis and finally calcification; especially following supracondylar fracture of humerus

---

**Osteomyelitis**

**Etiology**
- most commonly caused by *Staphylococcus aureus*
- mechanism of spread: hematogenous (most common) vs. direct-inoculation vs. contiguous focus
- risk factors: recent trauma/surgery, immunocompromised patients, DM, IV drug use, poor vascular supply, peripheral neuropathy

**Clinical Presentation**
- symptoms: pain and fever
- on exam: erythema, tenderness, edema common ± abscess/draining sinus tract; impaired function/WB

**Diagnosis**
- see Medical Imaging, MI24
- workup includes: WBC and diff, ESR, CRP, blood culture, aspirate culture/bone biopsy

**Table 6. Treatment of Osteomyelitis**

<table>
<thead>
<tr>
<th>Acute Osteomyelitis</th>
<th>Chronic Osteomyelitis</th>
</tr>
</thead>
<tbody>
<tr>
<td>IV antibiotics 4-6 wk; started empirically and adjusted after obtaining blood and aspirate cultures ± surgery (I&amp;D) for abscess or significant involvement ± hardware removal (if present)</td>
<td>Surgical debridement Antibiotics: both local (e.g. antibiotic beads) and systemic (IV)</td>
</tr>
</tbody>
</table>

---

**Septic Joint**

**Etiology**
- most commonly caused by *Staphylococcus aureus* in adults
- consider coagulase-negative *Staphylococcus* in patients with prior joint replacement
- consider *Neisseria gonorrhoeae* in sexually active adults and newborns
- risk factors: age >80 yr, DM, RA, prosthetic joint, recent joint surgery, skin infection/ulcer, IV drug use, alcoholism, previous intra-articular corticosteroid injection

**Clinical Presentation**
- inability/refusal to bear weight, localized joint pain, erythema, warmth, swelling, pain on active and passive ROM, ± fever

**Investigations**
- x-ray (to rule out fracture, tumor, metabolic bone disease), ESR, CRP, WBC, blood cultures
- joint aspirate: WBC >80,000 with >90% neutrophils, protein level >4.4 mg/dL, joint glucose level < blood glucose level, no crystals, positive Gram stain results
- listen for heart murmur (to reduce suspicion of infective endocarditis, use Duke Criteria)

**Treatment**
- IV antibiotics, empiric therapy (based on age and risk factors), adjust following joint aspirate C&S results
- for small joints: needle aspiration, serial if necessary until sterile
- for major joints such as knee, hip, or shoulder: urgent decompression and surgical drainage
Shoulder

Shoulder Dislocation

Prognosis
- recurrence rate depends on age of first dislocation: <20 yr = 65-95%; 20-40 yr = 60-70%; >40 yr = 2-4%

Specific Complications
- rotator cuff or capsular tear, shoulder stiffness
- injury to axillary nerve/artery, brachial plexus
- recurrent/unreduced dislocation (most common complication)

Investigations
- anterior dislocation x-rays (AP, trans-scapular, axillary views)
- posterior dislocation x-rays (AP, trans-scapular, axillary) or CT scan

Table 7. Anterior and Posterior Shoulder Dislocation

SPECTRUM OF DISEASE: IMPINGEMENT, TENDONITIS, MICRO OR MACRO TEARS

Etiology

- impingement: “painful arc syndrome”, compression of rotator cuff tendons (primarily supraspinatus) and subacromial bursa between the head of the humerus and the undersurface of acromion, AC joint, and CA ligament
  - leads to bursitis, tendinitis, and if left untreated, can lead to rotator cuff thinning and tear

Figure 14. Muscles of the rotator cuff
• anything that leads to a narrow subacromial space
  ▪ glenohumeral muscle weakness leading to abnormal motion of humeral head
  ▪ scapular muscle weakness leading to abnormal motion of acromion
  ▪ acromial abnormalities such as congenital narrow space or osteophyte formation

Clinical Features
• night pain and difficulty sleeping on affected side
• pain worse with active motion; passive movement generally permitted
• weakness and loss of ROM especially between 90°-130° (e.g. trouble with overhead activities)
• tenderness to palpation over greater tuberosity
• rule out bicep tendinosis: Speed and Yergason’s tests; SLAP lesion: O’Brien’s test

Table 9. Rotator Cuff Special Tests

<table>

<td>Rotator cuff impingement: shoulder flexion to 90° and passive internal rotation</td>
<td>Pain with internal rotation suggests impingement</td>
</tr>
<tr>
<td>Painful Arc Test</td>
<td>Rotator cuff tendinopathy: patient instructed to actively abduct the shoulder</td>
<td>Pain with abduction &gt; 90° suggests tendinopathy</td>
</tr>
</tbody>
</table>

Figure 15. Rotator cuff tests
Investigations
- x-rays: AP view may show high riding humerus relative to glenoid, evidence of chronic tendinitis
- MRI: coronal/sagittal oblique and axial orientations are useful for assessing full/partial tears and tendinopathy ± arthrogram: geyser sign (injected dye leaks out of joint through rotator cuff tear)
- arthrogram: see full thickness tear, difficult to assess partial thickness tears

Treatment and Prognosis
- mild ("wear")
  - treatment is non-operative (physiotherapy, NSAIDs)
- moderate ("tear")
  - non-operative treatment ± steroid injection
- severe ("repair")
  - impingement that is refractory to 2-3 mo physiotherapy and 1-2 injections
  - may require arthroscopic or surgical repair, i.e. acromioplasty, rotator cuff repair

Acromioclavicular Joint Pathology

Mechanism
- fall onto shoulder with adducted arm (fall onto tip of shoulder)

Clinical Features
- palpate step deformity between distal clavicle and acromion (with dislocation)
- pain with adduction of shoulder and/or palpation over AC joint
- limited ROM

Investigations
- x-rays: AP, Zanca view (10-15° cephalic tilt), axillary ± stress views (10 lb weight in patient's hand)

Treatment
- non-operative (most common): sling 1-3 wk, ice, analgesia, rehabilitation
- operative
  - indications: AC and CC ligaments are both torn and/or clavicle displaced posteriorly
  - procedure: number of different approaches involving AC/CC ligament reconstruction or screw/hook plate insertion

Table 10. Rockwood Classification of Acromioclavicular Joint Separation

<table>
<thead>
<tr>
<th>Grade</th>

<td>Most non-operative, operative if laborer or high level athlete</td>
</tr>
<tr>
<td>IV-VI</td>
<td>Based on the anatomical structure the displaced clavicle is in proximity with</td>
<td>Operative in most cases</td>
</tr>
</tbody>
</table>

Clavicle Fracture

Mechanism
- fall on shoulder (87%), direct trauma to clavicle (7%), FOOSH (6%)

Clinical Features
- pain and tenting of skin
- arm is clasped to chest to splint shoulder and prevent movement

Treatment
- evaluate NVS of entire upper limb

Associated Injuries with Clavicle Fractures
- Up to 9% of clavicle fractures are associated with other fractures (most commonly rib fractures)
- Majority of brachial plexus injuries are associated with proximal third fractures
• medial and middle third clavicle fractures  
  ▪ figure-of-eight sling x 1-2 wk  
  ▪ early ROM and strengthening once pain subsides  
  ▪ if ends overlap >2 cm consider ORIF  
• distal third clavicle fractures  
  ▪ undisplaced (with ligaments intact): sling x 1-2 wk  
  ▪ displaced (CC ligament injury): ORIF  

Specific Complications (see General Fracture Complications, OR6)  
• cosmetic bump usually only complication  
• shoulder stiffness, weakness with repetitive activity  
• pneumothorax, brachial plexus injuries, and subclavian vessel (all very rare)

Frozen Shoulder (Adhesive Capsulitis)

Definition  
• disorder characterized by progressive pain and stiffness of the shoulder usually resolving spontaneously after 18 mo

Mechanism  
• primary adhesive capsulitis  
  ▪ idiopathic, usually associated with DM  
  ▪ usually resolves spontaneously in 9-18 mo  
• secondary adhesive capsulitis  
  ▪ due to prolonged immobilization  
  ▪ shoulder-hand syndrome: CRPS/RSD characterized by arm and shoulder pain, decreased motion, and diffuse swelling  
  ▪ following MI, stroke, shoulder trauma  
  ▪ poorer outcomes

Clinical Features  
• gradual onset (wk to mo) of diffuse shoulder pain with:  
  ▪ decreased active AND passive ROM  
  ▪ pain worse at night and often prevents sleeping on affected side  
  ▪ increased stiffness as pain subsides: continues for 6-12 mo after pain has disappeared

Investigations  
• x-rays may be normal, or may show demineralization from disease

Treatment  
• Freezing Phase  
  ▪ active and passive ROM (physiotherapy)  
  ▪ NSAIDs and steroid injections if limited by pain  
• Thawing Phase  
  ▪ manipulation under anesthesia and early physiotherapy  
  ▪ arthroscopy for debridement/decompression

Humerus

Proximal Humeral Fracture

Mechanism  
• young: high energy trauma (MVC)  
• elderly: FOOSH from standing height in osteoporotic individuals

Clinical Features  
• proximal humeral tenderness, deformity with severe fracture, swelling, painful ROM, bruising extends down arm later

Investigations  
• test axillary nerve function (deltoid contraction and skin over deltoid)  
• x-rays: AP, trans-scapular, axillary are essential  
• CT scan: to evaluate for articular involvement and fracture displacement

Classification  
• Neer classification is based on 4 fracture fragments (see Neer Classification sidebar, OR16)  
  ▪ displaced: displacement >1 cm and/or angulation >45°
• the Neer system regards displacement, not the fracture line, as meeting criteria for a ‘part’ in the classification scheme
• ± dislocated/subluxed: humeral head dislocated/subluxed from glenoid

**Treatment**
- treat osteoporosis if needed
- non-operative
  - nondisplaced - broad arm sling immobilization begin ROM in 7-10 d to prevent stiffness
  - minimally displaced - closed reduction with sling immobilization x 2 wk, gentle ROM
- operative
  - ORIF (anatomic neck fractures, displaced, associated dislocated glenohumeral joint)
  - hemiarthroplasty may be necessary, especially in elderly

**Specific Complications** (see General Fracture Complications, OR6)
- AVN, axillary nerve palsy, malunion, post-traumatic arthritis

## Humeral Shaft Fracture

**Mechanism**
- direct blows/MVC (most common), FOOSH, twisting injuries, metastases (in elderly)

**Clinical Features**
- pain, swelling, ± shortening, motion/crepitus at fracture site
- must test radial nerve function before and after treatment: look for drop wrist, sensory impairment dorsum of hand

**Investigations**
- x-rays: AP and lateral radiographs of the humerus including the shoulder and elbow joints

**Treatment**
- in general, humeral shaft fractures are treated non-operatively
- non-operative (most common)
  - ± reduction; can accept deformity due to compensatory ROM of shoulder
  - hanging cast (weight of arm in cast provides traction across fracture site) with collar and cuff sling immobilization until swelling subsides, then Sarmiento functional brace, followed by ROM
- operative
  - indications: open fracture, neurovascular injury, unacceptable fracture alignment, polytrauma, segmental fracture, pathological fracture, “floating elbow” (simultaneous unstable humeral and forearm fractures), intra-articular
  - ORIF: plating (most common), IM rod insertion, external fixation

**Specific Complications** (see General Fracture Complications, OR6)
- radial nerve palsy: expect spontaneous recovery in 3-4 mo, otherwise send for EMG
- non-union: most frequently seen in middle 1/3
- decreased ROM
- compartment syndrome

## Elbow

### Supracondylar Fracture

- most common in pediatric population (peak age ~7 yr old), rarely seen in adults
- fracture of the distal 1/3 of humerus just proximal to capitulum and trochlea, usually transverse
- AIN injury commonly associated with extension type

**Mechanism**
- >96% are extension injuries via FOOSH (e.g. fall off monkey bars); <4% are flexion injuries

**Clinical Features**
- pain, swelling, point tenderness
- neurovascular injury: assess median and radial nerves, radial artery (check radial pulse)

**Investigations**
- x-rays: AP, lateral of elbow
- disruption of anterior humeral line suggests supracondylar fracture

[Figure 17. X-ray of transverse displaced supracondylar fracture of humerus with elbow dislocation]
Treatment
• reduction indications: evidence of arterial obstruction, unacceptable angulation, displaced (>50%)
• non-operative
  ▪ nondisplaced: long arm plaster slab in 90° flexion x 3 wk
• operative
  ▪ indications: displaced, vascular injury, open fracture
  ▪ requires percutaneous pinning followed by limb cast with elbow flexed <90°
  ▪ in adults, ORIF is necessary

Specific Complications (see General Fracture Complications, OR6)
• stiffness is most common
• brachial artery injury (kinking can occur if displaced fracture), median or ulnar nerve injury, compartment syndrome (leads to Volkmann's ischemic contracture), malalignment cubitus varus (distal fragment tilted into varus)

Radial Head Fracture

• a common fracture of the upper limb in young adults

Mechanism
• FOOSH with elbow extended and forearm pronated

Clinical Features
• marked local tenderness on palpation over radial head (lateral elbow)
• decreased ROM at elbow, mechanical block to forearm pronation and supination
• pain on pronation/supination

Investigations
• x-ray: enlarged anterior fat pad ("sail sign") or the presence of a posterior fat pad indicates effusion which could occur with occult radial head fractures

<td>Comminuted fracture</td>
<td>Radial head excision ± prosthesis</td>
</tr>
<tr>
<td>4</td>
<td>Comminuted fracture with posterior elbow dislocation</td>
<td>Radial head excision ± prosthesis</td>
</tr>
</tbody>
</table>

Specific Complications (see General Fracture Complications, OR6)
• myositis ossificans
• recurrent instability (if MCL injured and radial head excised)

Olecranon Fracture

Mechanism
• direct trauma to posterior aspect of elbow (fall onto the point of the elbow)

Clinical Features
• ≥ loss of active extension due to avulsion of triceps tendon

Investigations
• x-rays: AP + lateral (require true lateral to determine fracture pattern)

Treatment
• non-displaced (<2 mm, stable): cast x 3 wk (elbow in 90° flexion) then gentle ROM
• displaced: ORIF (plate and screws or tension band wiring) and early ROM if stable

Elbow Dislocation

• third most common joint dislocation after shoulder and patella
• usually the radius and ulna are dislocated together, or the radius head dislocates and the ulna remains ("Monteggia")
• anterior capsule and collateral ligaments disrupted

Terrible Triad
• Radial head fracture
• Coronoid fracture
• Elbow dislocation

To avoid stiffness do not immobilize elbow joint >2-3 wk

The anterior humeral line refers to an imaginary line along the longitudinal axis of the radius that passes through the center of the capitellum regardless of the degree of elbow flexion; if the radio-capitellar line does not pass through the center of the capitellum a dislocation should be suspected
Mechanism
• elbow hyperextension via FOOSH or valgus/supination stress during elbow flexion
• usually the radius and ulna are dislocated together, or the radius head dislocates and the ulna remains ("Monteggia")
• 90% are posterior/posterolateral, anterior are rare and usually devastating

Clinical Features
• elbow pain, swelling, deformity
• flexion contracture
• ± absent radial or ulnar pulses

Treatment
• assess NVS before reduction: brachial artery, median and ulnar nerves (can become entrapped during manipulation)
• closed reduction under conscious sedation (post-reduction x-rays required)
• Parvin’s method: patient lies prone with arm hanging down; apply gentle traction downwards on wrist, as olecranon slips distally, gently lift up the arm at elbow to reduce joint
• long-arm splint with forearm in neutral rotation and elbow in 90° flexion
• early ROM (<2 wk)

Specific Complications (see General Fracture Complications, OR6)
• stiffness (loss of extension), intra-articular loose body, neurovascular injury (ulnar nerve, median nerve, brachial artery), radial head fracture
• recurrent instability uncommon

Epicondylitis
• lateral epicondylitis = "tennis elbow", inflammation of the common extensor tendon as it originates from the lateral epicondyle
• medial epicondylitis = "golfer’s elbow", inflammation of the common flexor tendon as it originates from the medial epicondyle

Mechanism
• repeated or sustained contraction of the forearm muscles/chronic overuse

Clinical Features
• point tenderness over humeral epicondyle and/or distal to it
• pain upon resisted wrist extension (lateral epicondylitis) or wrist flexion (medial epicondylitis)
• generally a self-limited condition, but may take 6-18 mo to resolve

Treatment
• rest, ice, NSAIDs
• use brace/strap
• physiotherapy, stretching, and strengthening
• corticosteroid injection
• surgery: percutaneous or open release of common tendon from epicondyle (only after 6-12 mo of conservative therapy)

Forearm

Radius and Ulna Fracture

Mechanism
• commonly a FOOSH or high-energy direct blow
• fractures usually accompanied by displacement due to high force

Investigations
• x-ray: 1) AP and lateral of forearm; 2) AP, lateral, oblique of elbow and wrist
• CT if fracture is close to joint

Treatment
• goal is anatomic reduction since imperfect alignment significantly limits forearm pronation and supination
• ORIF with plates and screws; closed reduction with immobilization usually yields poor results for displaced forearm fractures (except in children)

Complications (see General Fracture Complications, OR6)
• soft tissue contracture resulting in limited forearm rotation – surgical release of tissue may be warranted

Bado Type Classification of Monteggia Fractures
Based on the direction of displacement of the dislocated radial head, generally the same direction as the apex of the ulnar fracture
Type I: anterior dislocation of radial head (60%)
Type II: posterior dislocation of radial head (15%)
Type III: lateral dislocation of radial head (20%)
Type IV – combined: proximal fracture of the ulna and radius, dislocation of the radial head in any direction (<5%)
Monteggia Fracture

- more common and better prognosis in the pediatric age group when compared to adults

Definition
- fracture of the proximal ulna with radial head dislocation and proximal radioulnar joint injury

Mechanism
- direct blow on the posterior aspect of the forearm
- hyperpronation
- fall on the hyperextended elbow

Clinical Features
- decreased rotation of forearm ± palpable lump at the radial head
- ulna angled apex anterior and radial head dislocated anteriorly (rarely the reverse deformity occurs)

Treatment
- adults: ORIF of ulna with indirect radius reduction in 90% of patients
- splint and early post-operative ROM if elbow completely stable, otherwise immobilization in plaster with elbow flexed for 6 wk
- pediatrics: attempt closed reduction and immobilization in plaster with elbow flexed for Bado Type I-III, surgery for Type IV

Specific Complications (see General Fracture Complications, OR6)
- PIN: most common nerve injury; observe for 3 mo as most resolve spontaneously
- radial head instability/redislocation
- radioulnar synostosis

Nightstick Fracture

Definition
- isolated fracture of ulna without dislocation of radial head

Mechanism
- direct blow to forearm (e.g. holding arm up to protect face)

Treatment
- non-displaced: below elbow cast (~10 d) followed by forearm brace (~8 wk)
- displaced: ORIF if >50% shaft displacement or >10° angulation

Galeazzi Fracture

Definition
- fracture of the distal radial shaft with disruption of the DRUJ
- most commonly in the distal 1/3 of radius near junction of metaphysis/diaphysis
- 3x more common than Monteggia fracture

Mechanism
- hand FOOSH with axial loading of pronated forearm

Investigations
- x-rays
  - shortening of distal radius >5 mm relative to the distal ulna
  - widening of the DRUJ space on AP
  - dislocation of radius with respect to ulna on true lateral

Treatment
- ORIF of radius; afterwards assess DRUJ stability by balloting distal ulna relative to distal radius
- if DRUJ is stable and reducible, splint for 10-14 d with early ROM encouraged
- if DRUJ is unstable, ORIF or percutaneous pinning with long arm cast in supination x 6 wk
Wrist

Colles’ Fracture

Definition
• extra-articular transverse distal radius fracture (~2 cm proximal to the radiocarpal joint) with dorsal displacement ± ulnar styloid fracture

Epidemiology
• most common fracture in those >40 yr, especially in women and those with osteoporotic bone

Mechanism
• FOOSH

Clinical Features
• “dinner fork” deformity
• swelling, ecchymoses, tenderness

Investigations
• x-ray: AP and lateral wrist

Treatment
• goal is to restore radial height, radial inclination (22°), volar tilt (11°) as well as DRUJ stability and useful forearm rotation
• closed reduction (think opposite of the deformity):
  ▪ hematoma block (sterile prep and drape, local anesthetic injection directly into fracture site) or conscious sedation
  ▪ closed reduction: 1) traction with extension (exaggerate injury), 2) traction with ulnar deviation, pronation, flexion (of distal fragment – not at wrist)
  ▪ dorsal slab/below elbow cast for 5-6 wk
• x-ray x 1 wk for 3 wk and at cessation of immobilization to ensure reduction is maintained
• obtain post-reduction films immediately; repeat reduction if necessary, consider external fixation or ORIF if failure of adequate closed reduction

Smith’s Fracture

Definition
• volar displacement of the distal radius (i.e. reverse Colles’ fracture)

Mechanism
• fall onto the back of the flexed hand

Treatment
• usually unstable and needs ORIF
• if patient is poor operative candidate, may attempt non-operative treatment
• closed reduction with hematoma block (reduction opposite of Colles’)
• long-arm cast in supination x 6 wk

Complications of Wrist Fractures

• most common complications are poor grip strength, stiffness, and radial shortening
• distal radius fractures in individuals <40 yr of age are usually highly comminuted and are likely to require ORIF
• 80% have normal function in 6-12 mo

Figure 23. Colles’ fracture and associated bony deformity

Figure 24. Normal wrist angles + wrist angles in Colles’ fracture
Note the relative shortening of the radius relative to the ulna on AP view in Colles’ fracture
Scaphoid Fracture

Epidemiology
• common in young men; not common in children or in patients beyond middle age
• most common carpal bone injured
• may be associated with other carpal or wrist injuries (e.g. Colles’ fracture)

Mechanism
• FOOSH: impaction of scaphoid on distal radius, most commonly resulting in a transverse fracture through the waist (65%), distal (10%), or proximal (25%) scaphoid

Clinical Features
• pain with wrist movement
• tenderness in the anatomical “snuff box”, over scaphoid tubercle, and pain with long axis compression into scaphoid
• usually nondisplaced

Investigations
• x-ray: PA, lateral, scaphoid views with wrist extension and ulnar deviation x 2 wk
• ± CT or MRI
• bone scan rarely used
• note: a fracture may not be radiologically evident up to 2 wk after acute injury, so if a patient complains of wrist pain and has anatomical snuff box tenderness but a negative x-ray, treat as if positive for a scaphoid fracture and repeat x-ray 2 wk later to rule out a fracture; if x-ray still negative order CT or MRI

Treatment
• early treatment critical for improving outcomes
• non-displaced (<1 mm displacement/<15° angulation): long-arm thumb spica cast x 4 wk then short arm cast until radiographic evidence of healing is seen (2-3 mo)
• displaced: ORIF with headless/countersink compression screw is the mainstay treatment, or percutaneous K-wire fixation (uncommon)

Specific Complications (see General Fracture Complications, OR6)
• most common: non-union/mal-union (use bone graft from iliac crest or distal radius with fixation to heal)
• AVN of the proximal fragment
• delayed union (recommend surgical fixation)

Prognosis
• fractures of the proximal third of the scaphoid have 70% rate of non-union or AVN
• waist fractures have healing rates of 80-90%
• distal third fractures have healing rates close to 100%

Cervical Spine

#### General Principles
- C1 (atlas): no vertebral body, no spinous process
- C2 (axis): odontoid = dens
- 7 cervical vertebrae; 8 cervical nerve roots
- nerve root exits above vertebra (i.e. C4 nerve root exits above C4 vertebra), C8 nerve root exits below C7 vertebra
- radiculopathy = impingement of nerve root
- myelopathy = impingement of spinal cord

#### Special Testing
- compression test: pressure on head worsens radicular pain
- distraction test: traction on head relieves radicular symptoms
- Valsalva test: Valsalva maneuver increases intrathecal pressure and causes radicular pain

#### Table 14. Cervical Radiculopathy/Neuropathy

X-Rays for C-Spine

- AP spine: alignment
- AP odontoid: atlantoaxial articulation
- lateral
  - vertebral alignment: posterior vertebral bodies should be aligned (translation >3.5 mm is abnormal)
  - angulation: between adjacent vertebral bodies (>11° is abnormal)
  - disc or facet joint widening
  - anterior soft tissue space (at C3 should be ≤3 mm; at C4 should be ≤8-10 mm)
- oblique: evaluate pedicles and intervertebral foramen
- ± swimmer’s view: lateral view with arm abducted 180° to evaluate C7-T1 junction if lateral view is inadequate
- ± lateral flexion/extension view: evaluate subluxation of cervical vertebrae

Differential Diagnosis of C-Spine Pain

- neck muscle strain, cervical spondylosis, cervical stenosis, RA (spondylitis), traumatic injury, whiplash, myofascial pain syndrome

C-SPINE INJURY

- see Neurosurgery, NS33

Thoracolumbar Spine

#### General Principles
- spinal cord terminates at conus medullaris (L1)
- individual nerve roots exit below pedicle of vertebra (i.e. L4 nerve root exits below L4 pedicle)
Special Tests
- straight leg raise: passive lifting of leg (30-70°) reproduces radicular symptoms of pain radiating down posterior/lateral leg to knee ± into foot
- Lasegue maneuver: dorsiflexion of foot during straight leg raise makes symptoms worse or, if leg is less elevated, dorsiflexion will bring on symptoms
- femoral stretch test: with patient prone, flexing the knee of the affected side and passively extending the hip results in radicular symptoms of unilateral pain in lumbar region, buttock, or posterior thigh

Differential Diagnosis of Back Pain
1. mechanical or nerve compression (>90%)
   - degenerative (disc, facet, ligament)
   - peripheral nerve compression (disc herniation)
   - spinal stenosis (congenital, osteophyte, central disc)
   - cauda equina syndrome
2. others (<10%)
   - neoplastic (primary, metastatic, multiple myeloma)
   - infectious (osteomyelitis, TB)
   - metabolic (osteoporosis)
   - traumatic fracture (compression, distraction, translation, rotation)
   - spondyloarthropathies (ankylosing spondylitis)
   - referred (aorta, renal, ureter, pancreas)

DEGENERATIVE DISC DISEASE
- loss of vertebral disc height with age results in:
  - bulging and tears of annulus fibrosus
  - change in alignment of facet joints
  - osteophyte formation
- can cause back-dominant pain
- management
  - non-operative
    - staying active with modified activity
    - back strengthening
    - NSAIDs
  - do not treat with opioids; no proven efficacy of spinal traction or manipulation
- operative – rarely indicated
  - decompression ± fusion
  - no difference in outcome between non-operative and surgical management at 2 yr

Cauda equina syndrome and ruptured aortic aneurysms are causes of low back pain that are considered surgical emergencies.

Red Flags for BACK PAIN
- Bowel or bladder dysfunction
- Anesthesia (saddle)
- Constitutional symptoms/malignancy
- Chronic disease
- Age >50 yr
- IV drug use
- Neuromotor deficits

Figure 29. Disc herniation causing nerve root compression
**SPINAL STENOSIS**
- definition: narrowing of spinal canal <10 mm
- etiology: congenital (idiopathic, osteopetrosis, achondroplasia) or acquired (degenerative, iatrogenic – post spinal surgery, ankylosing spondylitis, Paget’s disease, trauma)
- clinical features
  - ± bilateral back and leg pain
  - neurogenic claudication
  - ± motor weakness
  - normal back flexion; difficulty with back extension
- investigations: CT/MRI reveals narrowing of spinal canal, but gold standard = CT myelogram
- treatment
  - non-operative: vigorous physiotherapy (flexion exercises, stretch/strength exercises), NSAIDs, lumbar epidural steroids
  - operative: decompression surgery if conservative methods failed >6 mo

**Figure 30. Approach to back pain**

**MECHANICAL BACK PAIN**
- definition: back pain NOT due to prolapsed disc or any other clearly defined pathology
- clinical features
  - dull backache aggravated by activity
  - morning stiffness
  - no neurological signs
- treatment: symptomatic (analgesics, physiotherapy)
- prognosis: symptoms may resolve in 4-6 wk, others become chronic

**LUMBAR DISC HERNIATION**
- definition: tear in annulus fibrosus allows protrusion of nucleus pulposus causing either a central, posterolateral, or lateral disc herniation, most commonly at L5-S1 > L4-5 > L3-4
- etiology: usually a history of flexion-type injury
- clinical features
  - back dominant pain (central herniation) or leg dominant pain (lateral herniation)
  - tenderness between spinous processes at affected level
  - muscle spasm ± loss of normal lumbar lordosis
  - neurological disturbance is segmental and varies with level of central herniation
    - motor weakness (L4, L5, S1)
    - diminished reflexes (L4, S1)
    - diminished sensation (L4, L5, S1)
  - positive straight leg raise
  - positive Lasegue test
  - bowel or bladder symptoms, decreased rectal tone suggests cauda equina syndrome due to central disc herniation – surgical emergency
- investigations: MRI, consider a post-void residual volume to check for urinary retention; post-void >100 mL should heighten suspicion for cauda equina syndrome
- treatment
■ symptomatic
■ extension protocol (physiotherapy)
■ NSAIDs
■ 90% resolve in 3 mo; surgical discectomy reserved for progressive neurological deficit, failure of symptoms to resolve within 3 mo, or cauda equina syndrome due to central disc herniation

SPONDYLOYSIS
• definition: defect in the pars interarticularis with no movement of the vertebral bodies
• etiology
  ■ trauma: gymnasts, weightlifters, backpackers, loggers, laborers
• clinical features: activity-related back pain, pain with unilateral extension (Michelis’ test)
• investigations
  ■ oblique x-ray: “collar” break in the “Scottie dog’s” neck
  ■ bone scan
  ■ CT scan
• treatment: activity restriction, brace, stretching exercise

SPONDYLOLISTHESIS
• definition: defect in pars interarticularis causing a forward slip of one vertebra on another usually at L5-S1, less commonly at L4-5
• etiology: congenital (children), degenerative (adults), traumatic, pathological, teratogenic
• clinical features: lower back pain radiating to buttocks

Specific Complications
• may present as cauda equina syndrome due to roots being stretched over the edge of L5 or sacrum

Pelvis

Pelvic Fracture

Mechanism
• young: high energy trauma, either direct or by force transmitted longitudinally through the femur
• elderly: fall from standing height, low energy trauma
• lateral compression (most common), vertical shear, or anteroposterior compression fractures

Clinical Features
• local swelling, tenderness
• deformity of lower extremity
• pelvic instability

Investigations
• x-ray: AP pelvis, inlet and outlet views, Judet views (obturatar and iliac oblique for acetabular fracture)
  ■ 6 cardinal radiographic lines of the acetabulum: ilioischial line, iliopectineal line, tear drop, roof, posterior rim, anterior rim
• CT scan useful for evaluating posterior pelvic injury and acetabular fracture
Classification

Treatment

- ABCDEs
- assess genitourinary injury (rectal exam, vaginal exam, hematuria, blood at urethral meatus)
  - if involved, the fracture is considered an open fracture
- stable fractures: non-operative treatment, protected weight bearing
- emergency management
  - IV fluids/blood
  - pelvic binder/sheeting
  - external fixation vs. emergent angiography/embolization
  - ± laparotomy (if FAST/DPL positive)
- indications for operative treatment
  - unstable pelvic ring injury
  - disruption of anterior and posterior SI ligament
  - symphysis diastasis >2.5 cm
  - vertical instability of the posterior pelvis

Specific Complications (see General Fracture Complications, OR6)

- hemorrhage (life-threatening)
- injury to rectum or urogenital structures
- obstetrical difficulties, sexual and voiding dysfunction
- persistent SI joint pain
- post-traumatic arthritis of the hip with acetabular fractures
- high risk of DVT/PE

Hip

Hip Dislocation

- full trauma survey (see Emergency Medicine, Initial Patient Assessment/Management, ER2)
- examine for neurovascular injury PRIOR to open or closed reduction
- reduce hip dislocations ASAP (ideally within 6 h) to decrease risk of AVN of the femoral head
- hip precautions (no extreme hip flexion, adduction, internal or external rotation) for 6 wk post-reduction
- see Hip Dislocation after Total Hip Arthroplasty, OR28

ANTERIOR HIP DISLOCATION

- mechanism: posteriorly directed blow to knee with hip widely abducted
- clinical features: shortened, abducted, externally rotated limb
- treatment
  - closed reduction under conscious sedation/GA
  - post-reduction CT to assess joint congruity

POSTERIOR HIP DISLOCATION

- most frequent type of hip dislocation
- mechanism: severe force to knee with hip flexed and adducted
  - e.g., knee into dashboard in MVC
- clinical features: shortened, adducted, internally rotated limb
- treatment
  - closed reduction under conscious sedation/GA only if associated femoral neck fracture
  - ORIF if unstable, intra-articular fragments or posterior wall fracture
  - post-reduction CT to assess joint congruity and fractures
  - if reduction is unstable, put in traction x 4-6 wk
CENTRAL HIP DISLOCATION (rare)
- traumatic injury where femoral head is pushed medially through acetabulum

COMPLICATIONS FOR ALL HIP DISLOCATIONS
- post-traumatic OA
- AVN of femoral head
- fracture of femoral head, neck, or shaft
- sciatic nerve palsy in 25% (10% permanent)
- HO
- thromboembolism – DVT/PE

Hip Fracture

General Features
- acute onset of hip pain
- unable to weight-bear
- shortened and externally rotated leg
- painful ROM

Table 20. Overview of Hip Fractures

</table>

AVN of Femoral Head
- Distal to proximal blood supply along femoral neck to head (medial and lateral femoral circumflex arteries)
- Susceptible to AVN if blood supply disrupted
- Etiology: femoral neck fracture, chronic systemic steroid use, SCFE, Legg-Calvé-Perthes, SLE, RA
**Arthritis of the Hip**

**Etiology**
- OA, inflammatory arthritis, post-traumatic arthritis, late effects of congenital hip disorders, or septic arthritis

**Clinical Features**
- pain (groin, medial thigh) and stiffness aggravated by activity
- morning stiffness >1 h, multiple joint swelling, hand nodules (RA)
- decreased ROM (internal rotation is lost first)
- crepitus
- ± fixed flexion contracture leading to apparent limb shortening (Thomas test)
- ± Trendelenberg sign

**Investigations**
- x-ray
  - OA: joint space narrowing, subchondral sclerosis, subchondral cysts, osteophytes
  - RA: osteopenia, erosion, joint space narrowing, subchondral cysts, symmetric joint space narrowing
- blood work: ANA, RF

**Treatment**
- non-operative: weight reduction, activity modification, physiotherapy, analgesics, walking aids
- operative: realign = osteotomy; replace = arthroplasty; fuse = arthrodesis
- complications with arthroplasty: component loosening, dislocation, HO, thromboembolism, infection, neurovascular injury, limb length discrepancy
- arthroplasty is standard of care in most patients with hip arthritis

**Hip Dislocation after Total Hip Arthroplasty**

**Etiology**
- THA that is unstable when hip is flexed, adducted and internally rotated, or extended and externally rotated (avoid flexing hip >90° or crossing legs for ~6 wk after surgery)

**Epidemiology**
- occurs in 1-4% of primary THA and 10-16% of revision THAs
- risk factors: neurological impairment, post-traumatic arthritis, revision surgery, substance abuse

**Treatment**
- external abduction splint to prevent hip adduction
- constrained acetabular component for recurrent dislocation if no issue with position of acetabular/femoral implants + knee immobilizer

**Complications**
- sciatic nerve palsy in 25% (10% permanent)
- HO
Femur

Femoral Diaphysis Fracture

Mechanism
- high energy trauma (MVC, fall from height, gunshot wound)
- in children, can result from low energy trauma (spiral fracture)

Clinical Features
- shortened, externally rotated leg (if fracture displaced)
- inability to weight-bear
- often open injury, always a Gustilo III (see Table 5, OR9)

Investigations
- AP pelvis, AP/lateral hip, femur, knee

Complications
- hemorrhage requiring transfusion
- fat embolism leading to ARDS
- extensive soft tissue damage
- ipsilateral hip dislocation/fracture (2-6%)
- nerve injury

Treatment
- stabilize patient
- immobilize leg
- ORIF with anterograde or retrograde IM nail, external fixator for unstable patients, open fractures, or highly vascular areas, or plate and screws for open growth plates within 24 h
- early mobilization and strengthening

Distal Femoral Fracture

Mechanism
- direct high energy force or axial loading
- three types in addition to classification as intra-articular or extra-articular

Clinical Features
- extreme pain
- knee effusion (hemarthrosis)
- shortened, externally rotated leg if displaced
- neurovascular deficits can occur with displaced fracture

Treatment
- ORIF if displaced or intra-articular; may choose to manage non-operatively if nondisplaced or incomplete fracture
- early mobilization and strengthening

Complications (see General Fracture Complications, OR6)
- femoral artery tear
- popliteal artery injury
- nerve injury
- extensive soft tissue injury
- angulation deformities

It is important to rule out ipsilateral femoral neck fracture as they occur in 2-6% of femoral diaphysis fractures and are reportedly missed in 19-31% of cases.

1. Posterior horn of lateral meniscus
2. Anterior horn of lateral meniscus
3. PCL
4. ACL
5. Posterior horn of medial meniscus
6. Anterior horn of medial meniscus

1. Posterior horn of lateral meniscus
2. Anterior horn of lateral meniscus
3. PCL
4. ACL
5. Posterior horn of medial meniscus
6. Anterior horn of medial meniscus

Figure 39. Diagram of the right tibial plateau

It is important to rule out ipsilateral femoral neck fracture as they occur in 2-6% of femoral diaphysis fractures and are reportedly missed in 19-31% of cases.
Knee

Evaluation of Knee

Common Complaints

• general orthopedic history
• also inquire about common knee symptoms
  • locking: mechanical block to extension
  • torn meniscus/loose body in joint
  • pseudo-locking: limited ROM without mechanical block
  • effusion, muscle spasm after injury, arthritis
  • painful clicking (audible)
  • torn meniscus
  • giving way: instability
  • cruciate ligament or meniscal tear, patellar dislocation

Special Tests of the Knee

• anterior and posterior drawer tests
  • demonstrate ACL and PCL, respectively
  • knee flexed at 90°, foot immobilized, hamstrings released
  • if able to sublux tibia anteriorly (anterior drawer test), then ACL may be torn
  • if able to sublux tibia posteriorly (posterior drawer test), then PCL may be torn
  • anterior drawer test for ACL: 3.8 positive likelihood ratio, 0.30 negative likelihood ratio

• Lachmann test
  • demonstrates torn ACL
  • hold knee in 10-20° flexion, stabilizing the femur
  • try to sublux tibia anteriorly on femur
  • similar to anterior drawer test, more reliable due to less muscular stabilization
  • for ACL: 25.0 positive likelihood ratio, 0.1 negative likelihood ratio

• Thessaly test
  • demonstrates meniscal tear
  • patient stands flat footed on one leg while the examiner provides his or her hands for balance. The patient then flexes the knee to 20° and rotates the femur on the tibia medially and laterally three times while maintaining the 20° flexion
  • positive for a meniscal tear if the patient experiences medial or lateral joint line discomfort
  • for medial meniscus: 29.67 positive likelihood ratio, 0.11 negative likelihood ratio
  • for lateral meniscus: 23.0 positive likelihood ratio, 0.083 negative likelihood ratio

• posterior sag sign
  • demonstrates torn PCL
  • may give a false positive anterior draw sign
  • flex knees and hips to 90°, hold ankles and knees
  • view from the lateral aspect
  • if one tibia sags posteriorly compared to the other, its PCL is torn

• pivot shift sign
  • demonstrates torn ACL
  • start with the knee in extension
  • internally rotate foot, slowly flex knee while palpating and applying a valgus force
  • normal knee will flex smoothly
  • if incompetent ACL, tibia will sublux anteriorly on femur at start of maneuver. During flexion, the tibia will reduce and externally rotate about the femur (the ‘pivot’)
  • reverse pivot shift (start in flexion, externally rotate, apply valgus and extend knee) suggests torn PCL
  • composite assessment for ACL: 25.0 positive likelihood ratio, 0.04 negative likelihood ratio
  • composite assessment for PCL: 21.0 positive likelihood ratio, 0.05 negative likelihood ratio

• collateral ligament stress test
  • palpate ligament for ‘opening’ of joint space while testing
  • with knee in full extension, apply valgus force to test MCL, apply varus force to test LCL
  • repeat tests with knee in 20° flexion to relax joint capsule
  • opening only in 20° flexion due to MCL damage only
  • opening in 20° of flexion and full extension is due to MCL, cruciate, and joint capsule damage

• tests for meniscal tear
  • joint line tenderness
  • joint line pain when palpated
  • palpate one side at a time and watch patient’s eyes
  • for meniscal tear: 0.9 positive likelihood ratio, 1.1 negative likelihood ratio
  • crouch compression test
  • joint line pain when squatting (anterior pain suggests patellofemoral pathology)
Murray's test useful collaborative information
- with knee in flexion, palpate joint line for painful “pop/click”
- internally rotate foot, varus stress, and extend knee to test lateral meniscus
- externally rotate foot, valgus stress, and extend knee to test medial meniscus
- for meniscal tear: 1.3 positive likelihood ratio, 0.8 negative likelihood ratio
- composite assessment for meniscal tears: 2.7 positive likelihood ratio, 0.4 negative likelihood ratio

X-Rays
- AP standing, lateral
- skyline: tangential view with knees flexed at 45° to see patellofemoral joint
- 3-foot standing view: useful in evaluating leg length and varus/valgus alignment
- Ottawa Knee Rules (see Emergency Medicine, ER17)

Cruciate Ligament Tears
- ACL tear much more common than PCL tear

<table>

</tbody>
</table>

Collateral Ligament Tears

**Mechanism**
- valgus force to knee = MCL tear
- varus force to knee = LCL tear

**Clinical Features**
- swelling/effusion
- tenderness above and below joint line medially (MCL) or laterally (LCL)
- joint laxity with varus or valgus force to knee
- laxity with endpoint suggests partial tear
- laxity with no endpoint suggests a complete tear
- test for other injuries (e.g. O'Donoghue's unhappy triad), common peroneal nerve injury

**Treatment**
- partial tear: immobilization x 2-4 wk with early ROM and strengthening
- complete tear: immobilization at 30° flexion
- multiple ligamentous injuries: surgical repair of ligaments
Meniscal Tears

• Medial tear much more common than lateral tear

Mechanism
• Twisting force on knee when it is partially flexed (e.g., stepping down and turning)
• Requires moderate trauma in young person but only mild trauma in elderly due to degeneration

Clinical Features
• Immediate pain, difficulty weight-bearing, instability, and clicking
• Increased pain with squatting and/or twisting
• Effusion (hemarthrosis) with insidious onset (24-48 h after injury)
• Joint line tenderness medially or laterally
• Locking of knee (if portion of meniscus mechanically obstructing extension)

Investigations
• MRI, arthroscopy

Treatment
• If not locked: ROM and strengthening (NSAIDs)
• If locked or failed above: arthroscopic repair/partial meniscectomy

Quadriceps/Patellar Tendon Rupture

Mechanism
• Sudden forceful contraction of quadriceps during an attempt to stop
• More common in obese patients and those with pre-existing degenerative changes in tendon
  • DM, SLE, RA, steroid use, renal failure on dialysis

Clinical Features
• Inability to extend knee or weight-bear
• Possible audible “pop”
• Patella in lower or higher position with palpable gap above or below patella respectively
• May have an effusion

Investigations
• Ask patient to straight leg raise
• Knee x-ray to rule out patellar fracture
• Lateral view: patella alta with patella tendon rupture, patella baja (infera) with quadriceps tendon rupture

Treatment
• Non-operative treatment for incomplete tears with preserved extension of knee
• Surgical repair of tendon indicated for complete ruptures
• Early surgical repair: better outcomes compared with delayed repair (>6 wk post injury)
• Delayed repair complicated by quadriceps contracture, patella migration, and adhesions

Dislocated Knee

Mechanism
• High energy trauma
• By definition, caused by tears of multiple ligaments

Clinical Features
• Classified by relation of tibia with respect to femur
  • Anterior, posterior, lateral, medial, rotary
• Knee instability
• Effusion
• Pain
• Ischemic limb

Investigations
• X-rays: AP, lateral, skyline
  • Associated radiographic findings include tibial plateau fracture dislocations, proximal fibular fractures, and avulsion of fibular head
• Ankle brachial index (abnormal if <0.9)
• Arteriogram or CT angiogram if abnormal vascular exam (such as abnormal pedal pulses)
Treatment
• urgent closed reduction
  ▪ complicated by interposed soft tissue
• assessment of peroneal nerve, tibial artery, and ligamentous injuries
• repair of associated injuries; also may need decompressive fasciotomy especially if vascular repair undertaken
• knee immobilization x 6-8 wk

Specific Complications
• high incidence of associated injuries
  ▪ popliteal artery tear
  ▪ peroneal nerve injury
  ▪ capsular tear
• chronic: instability, stiffness, post-traumatic arthritis

Patella

Patellar Fracture

Mechanism
• direct blow to the patella: fall, MVC (dashboard)
• indirect trauma by sudden flexion of knee against contracted quadriceps

Clinical Features
• marked tenderness
• inability to extend knee or straight leg raise
• proximal displacement of patella
• patellar deformity
• ± effusion/hemarthrosis

Investigations
• x-rays: AP, lateral, skyline
• do not confuse with bipartite patella: congenitally unfused ossification centers with smooth margins on x-ray at superolateral corner

Treatment
• goal: restore extensor mechanism with maximal articular congruency
• non-displaced (step-off <2-3 mm and fracture gap <1-4 mm)
  ▪ straight leg immobilization 1-4 wk with hinged knee brace, weight bearing as tolerated
  ▪ progress in flexion after 2-3 wk
  ▪ physiotherapy: quadriceps strengthening when pain has subsided
• displaced: ORIF (>2 mm)
• comminuted: ORIF; may require partial/complete patellectomy
• disrupted extensor mechanism: ORIF

Patellar Dislocation

Mechanism
• usually a non-contact twisting injury
• lateral displacement of patella after contraction of quadriceps at the start of knee flexion in an almost straight knee joint
• direct blow, e.g. knee/helmet to knee collision

Risk Factors
• young, female
• obesity
• high-riding patella (patella alta)
• knock-knees (genu valgus)
• Q-angle (quadriceps angle) >20°
• shallow intercondylar groove
• weak vastus medialis
• tight lateral retinaculum
• ligamentous laxity (Ehlers-Danlos)

Clinical Features
• knee catches or gives way with walking
• severe pain, tenderness anteromedially from rupture of capsule
• weak knee extension or inability to extend leg unless patella reduced

Complications
• Symptomatic wiring
• Loss of reduction
• Osteonecrosis (proximal fragment)
• Hardware failure
• Knee stiffness
• Nonunion
• Infection

Figure 44. Types of patellar fractures

Figure 45. Q-angle
The angle between a vertical line through the patella and tibial tuberosity and a line from the ASIS to the middle patella. The larger the angle the greater the amount of lateral force on the knee (normal <20°)
• positive patellar apprehension test
  ▪ passive lateral translation results in guarding and patient apprehension
• often recurrent, self-reducing
• concomitant MCL injury

Investigations
• x-rays: AP, lateral, skyline view of patella
  ▪ check for fracture of medial patella (most common) and lateral femoral condyle

Treatment
• non-operative first
  ▪ NSAIDS, activity modification, and physical therapy
  ▪ short-term immobilization for comfort then 6 wk controlled motion
  ▪ progressive weight bearing and isometric quadriceps strengthening
• if recurrent or if loose bodies present
  ▪ surgical tightening of medial capsule and release of lateral retinaculum, possible tibial tuberosity transfer, or proximal tibial osteotomy

Patellofemoral Syndrome (Chondromalacia Patellae)

Mechanism
• softening, erosion and fragmentation of articular cartilage, predominantly medial aspect of patella
• commonly seen in active young females

Predisposing Factors
• malalignment causing patellar maltracking (Q angle ≥20°, genu valgus)
• post-trauma
• deformity of patella or femoral groove
• recurrent patellar dislocation, ligamentous laxity
• excessive knee strain (athletes)

Clinical Features
• deep, aching anterior knee pain
  ▪ exacerbated by prolonged sitting (theatre sign), strenuous athletic activities, stair climbing, squatting or kneeling
• insidious onset and vague in nature
• sensation of instability, pseudolocking
• pain with extension against resistance through terminal 30-40°
• pain with compression of patella with knee ROM
• swelling rare, minimal if present
• palpable crepitus

Investigations
• x-rays: AP, lateral, skyline

Treatment
• non-operative
  ▪ continue non-impact activities; rest and rehabilitation
  ▪ NSAIDs
  ▪ physiotherapy: vastus medialis and core strengthening
• surgical with refractory patients
  ▪ tibial tubercle elevation
  ▪ arthroscopic shaving/debridement
  ▪ lateral release of retinaculum
Tibia

Tibial Plateau Fracture

Mechanism
- varus/valgus load ± axial loading (e.g. fall from height)
- femoral condyles driven into proximal tibia
- can result from minor trauma in osteoporotics

Clinical Features
- frequency: lateral > medial
- medial fractures require higher energy – often have concomitant vascular injuries
- knee effusion
- inability to bear weight
- swelling
- associated with compartment syndrome

Classification
- Schatzker classification

Investigations
- x-rays: AP, lateral, oblique
- CT: pre-operative planning, identify articular depression and comminution

Treatment
- Approach #1 (based on amount of depression seen on x-ray)
  - If depression on x-ray is <3 mm:
    - Straight leg immobilization x 4-6 wk with progressive ROM weight bearing
  - If depression is >3 mm:
    - ORIF often requiring bone grafting to elevate depressed fragment
- Approach #2 (based on varus/valgus instability)
  - If minimal varus/valgus instability (<15°):
    - Straight leg immobilization x 4-6 wk with progressive ROM weight bearing
  - If significant varus/valgus instability (>15°):
    - ORIF often requiring bone grafting to elevate depressed fragment

Specific Complications (see General Fracture Complications, OR6)
- ligamentous injuries
- meniscal lesions
- AVN
- infection
- OA

Tibial Shaft Fracture

Mechanism
- low energy pattern: torsional injury
- high energy: including MVC, falls, sporting injuries

Clinical Features
- open vs. closed
- amount of displacement
- NVS
- most commonly fractured long bone
- most common open fracture

Investigations
- x-rays: AP, lateral, skyline
  - full length, plus knee and ankle

Treatment
- closed minimally displaced: straight leg cast x 4 wk, functional brace after
- displaced: ORIF with reamed IM nail, plate and screws, or external fixator
- open
  - antibiotics, I&D
  - external fixation or IM nail
  - vascularized coverage of soft tissue defects (often heal poorly)

Specific Complications (see General Fracture Complications, OR6)
- high incidence of neurovascular injury and compartment syndrome
- poor soft tissue coverage (critical to outcome)
Ankle

Evaluation of Ankle and Foot Complaints

Special Tests
• anterior drawer: examiner attempts to displace the foot anteriorly against a fixed tibia
• talar tilt: foot is stressed in inversion and angle of talar rotation is evaluated by x-ray

X-Ray
• AP, lateral
• mortise view: ankle at 15° of internal rotation
  ▪ gives true view of ankle joint
  ▪ joint space should be symmetric with no talar tilt
• Ottawa Ankle Rules should guide use of x-ray; nearly 100% sensitivity
• ± CT to better characterize fractures

Ankle Fracture

Mechanism
• pattern of fracture depends on the position of the ankle when trauma occurs
• generally involves
  ▪ ipsilateral ligamentous tears or transverse bony avulsion
  ▪ contralateral shear fractures (oblique or spiral)
• classification systems
  ▪ Danis-Weber
  ▪ Lauge-Hansen: based on foot’s position and motion relative to leg

Danis-Weber Classification
• based on level of fibular fracture relative to syndesmosis
  • Type A (infra-syndesmotic)
    ▪ pure inversion injury
    ▪ avulsion of lateral malleolus below plafond or torn calcaneofibular ligament
    ▪ ± shear fracture of medial malleolus
  • Type B (trans-syndesmotic)
    ▪ external rotation and eversion (most common)
    ▪ ± avulsion of medial malleolus or rupture of deltoid ligament
    ▪ spiral fracture of lateral malleolus starting at plafond
  • Type C (supra-syndesmotic)
    ▪ pure external rotation
    ▪ avulsion of medial malleolus or torn deltoid ligament
    ▪ ± posterior malleolus avulsion with posterior fibulotibial ligament
    ▪ fibular fracture is above plafond (called Maisonneuve fracture if at proximal fibula)
    ▪ frequently tears syndesmosis

Treatment
• undisplaced: NWB below knee cast
• indications for ORIF
  ▪ any fracture-dislocation: restore vascularity, minimize articular injury, reduce pain and skin pressure
  ▪ most of type B, and all of type C
  ▪ talo-malleolar (medial, posterior, lateral) fractures
  ▪ talar tilt >10°
  ▪ medial clear space on x-ray greater than superior clear space
  ▪ open fracture/open joint injury
• high incidence of post-traumatic arthritis
• wrinkle test: skin shows wrinkles, to determine if soft tissue swelling has resolved to an extent to reduce complications

Ligamentous Injuries

• see Figure 48 for ankle ligaments

Medial Ligament Complex (deltoid ligament)
• eversion injury
• usually avulses medial or posterior malleolus and strains syndesmosis
Lateral Ligament Complex (Anterior Talofibular, Calcaneofibular, Posterior Talofibular)
- inversion injury, >90% of all ankle sprains
- ATF most commonly and severely injured if ankle is plantar flexed
- swelling and tenderness anterior to lateral malleolus
- +++ ecchymoses
- positive ankle anterior drawer
- may have significant medial talar tilt on inversion stress x-ray

Treatment
- microscopic tear (Grade I)
  - rest, ice, compression, elevation (RICE)
- macroscopic tear (Grade II)
  - strap ankle in dorsiflexion and eversion x 4-6 wk
  - physiotherapy: strengthening and proprioceptive retraining
- complete tear (Grade III)
  - below knee walking cast x 4-6 wk
  - physiotherapy: strengthening and proprioceptive retraining
  - surgical intervention may be required if chronic symptomatic instability develops

Foot

Talar Fracture

Mechanism
- axial loading or hyperdorsiflexion (MVC, fall from height)
- 60% of talus covered by articular cartilage
- talar neck is most common fracture of talus (50%)
- tenuous blood supply runs distal to proximal along talar neck
  - high risk of AVN with displaced fractures

Investigations
- x-rays: AP, lateral, Canale view
- CT to better characterize fracture
- MRI can clearly define extent of AVN

Treatment
- undisplaced: NWB below knee cast x 20-24 wk
- displaced: ORIF (high rate of nonunion, AVN)
- neck fracture: Pin (nondisplaced) or ORIF

Calcaneal Fracture

Mechanism
- high energy, axial loading: fall from height onto heels
- 10% of fractures associated with compression fractures of thoracic or lumbar spine (rule out spine injury)
- 75% intra-articular and 10% are bilateral

Physical Exam
- marked swelling, bruising on heel/sole
- wider, shortened, flatter heel when viewed from behind
- varus heel

Investigations
- x-rays: AP, lateral, oblique (Broden’s view)
- loss of Bohler’s angle
- CT: gold-standard, assess intra-articular extension

Treatment
- closed vs. open reduction is controversial
- NWB cast x 3 mo with early ROM and strengthening
Achilles Tendonitis

Mechanism
- chronic inflammation from activity or poor-fitting footwear
- may also develop heel bumps (retrocalcaneobursitis)

Physical Exam
- pain, stiffness, and crepitus with ROM
- thickened tendon, palpable bump

Treatment
- rest, NSAIDs, shoe wear modification
- heel sleeves and pads are mainstay of non-operative treatment
- gentle gastrocnemius-soleus stretching, eccentric training with physical therapy, deep tissue calf massage
- orthotics, open back shoes
- shockwave therapy in chronic tendonitis
- DO NOT inject steroids (risk of tendon rupture)

Achilles Tendon Rupture

Mechanism
- loading activity, stop-and-go sports (e.g. squash, tennis, basketball)
- secondary to chronic tendonitis, steroid injection

Clinical Features
- audible pop, sudden pain with push off movement
- sensation of being kicked in heel when trying to plantar flex
- palpable gap
- apprehensive toe off when walking
- weak plantar flexion strength
- Thompson test: with patient prone, plantar flexion when calf is squeezed by examiner
  - no passive plantar flexion is positive test = ruptured tendon

Treatment
- low demand or elderly: cast foot in plantar flexion (to relax tendon) x 8-12 wk
- high demand: surgical repair, then cast as above x 6-8 wk

Plantar Fasciitis (Heel Spur Syndrome)

Mechanism
- repetitive strain injury causing microtears and inflammation of plantar fascia
- common in athletes (especially runners, dancers)
- also associated with obesity, DM, seronegative and seropositive arthritis

Clinical Features
- insidious onset of heel pain, pain when getting out of bed and stiffness
- intense pain when walking from rest that subsides as patient continues to walk, worse at end of day with prolonged standing
- swelling, tenderness over sole
- greatest at medial calcaneal tubercle and 1-2 cm distal along plantar fascia
- pain with toe dorsiflexion (stretches fascia)

Investigations
- plain radiographs to rule out fractures
- often see bony exostoses (heel spurs) at insertion of fascia into medial calcaneal tubercle
- spur is secondary to inflammation, not the cause of pain

Treatment
- pain control and stretching programs are first line
- rest, ice, NSAIDs, steroid injection
- physiotherapy: Achilles tendon and plantar fascia stretching, extracorporeal shockwave therapy
- orthotics with heel cup
  - to counteract pronation and disperse heel strike forces
- endoscopic surgical release of fascia in refractory cases
  - spur removal is not required

Complications of Achilles Tendon Rupture
- Infection
- Sural nerve injury
- Rerupture: surgical repair decreases likelihood of rerupture compared to non-operative management

The most common site of Achilles tendon rupture is 2-6 cm from its insertion where the blood supply is the poorest
Bunions (Hallux Valgus)

Mechanism
- valgus alignment on 1st MTP (hallux valgus) causes eccentric pull of extensor and intrinsic muscles
- many associated deformities in foot from altered mechanics
- reactive exostosis forms with thickening of the skin creating a bunion
- most often associated with poor-fitting footwear (high heel and narrow toe box)
- can be hereditary (70% have family history)
- 10x more frequent in women

Clinical Features
- painful bursa over medial eminence of 1st MT head
- pronation (rotation inward) of great toe
- numbness over medial aspect of great toe

Investigations
- x-ray: standing AP/lateral/sesamoid view, NWB oblique

Treatment
- indications: painful corn or bunion, overriding 2nd toe
- non-operative first line
  - properly fitted shoes (low heel) and toe spacer
- surgical: goal is to restore normal anatomy, not cosmetic reasons alone
  - osteotomy with realignment of 1st MTP joint (Chevron Procedure)
  - arthrodesis

Metatarsal Fracture

- as with the hand, 1st, 4th, 5th MT are relatively mobile, while the 2nd and 3rd are fixed
- use Ottawa Foot Rules to determine need for x-ray

Table 23. Types of Metatarsal Fractures

<table>

Pediatric Orthopedics

Fractures in Children

- type of fracture
  - thicker, more active periosteum results in pediatric specific fractures: greenstick (one cortex), torus (i.e. ‘buckle’, impacted cortex) and plastic (bowing)
  - distal radius fracture most common in children (phalanges second), the majority are treated with closed reduction and casting
  - adults fracture through both cortices
  - epiphyseal growth plate
    - weaker part of bone, susceptible to fractures
    - plate often mistaken for fracture on x-ray and vice versa (x-ray opposite limb for comparison), especially in elbow
    - tensile strength of bone < ligaments in children, therefore clinician must be confident that fracture and/or growth plate injury have been ruled out before diagnosing a sprain
    - intra-articular fractures have worse consequences in children because they usually involve the growth plate
• anatomic reduction
  • gold standard with adults
  • may cause limb length discrepancy in children (overgrowth)
  • accept greater angular deformity in children (remodeling minimizes deformity)
• time to heal
  • shorter in children
• always be aware of the possibility of child abuse
  • make sure stated mechanism compatible with injury
  • high index of suspicion with fractures in non-ambulating children (<1 yr); look for other
  signs, including x-ray evidence of healing fractures at different sites and different stages of
  healing

### Stress Fractures

**Mechanism**
- insufficiency fracture
  • stress applied to a weak or structurally deficient bone
- fatigue fracture
  • repetitive, excessive force applied to normal bone
- most common in adolescent athletes
- tibia is most common site

**Diagnosis and Treatment**
- localized pain and tenderness over the involved bone
- plain films may not show fracture for 2 wk
- bone scan positive in 12–15 d
- treatment is rest from strenuous activities to allow remodeling (can take several months)

### Evaluation of the Limping Child

• see Pediatrics, P93

## Epiphyseal Injury

### Table 24. Salter-Harris Classification of Epiphyseal Injury

<table>
<thead>
<tr>
<th>Type (Salter-Harris)</th>
<th>Description</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>I (Straight through; Stable)</td>
<td>Transverse through growth plate</td>
<td>Closed reduction and cast immobilization (except SCFE – ORIF); heals well, 95% do not affect growth</td>
</tr>
<tr>
<td>II (Above)</td>
<td>Through metaphysis and along growth plate</td>
<td>Closed reduction and cast if anatomic; otherwise ORIF</td>
</tr>
<tr>
<td>III (Low)*</td>
<td>Through epiphysis to plate and along growth plate</td>
<td>Anatomic reduction by ORIF to prevent growth arrest, avoid fixation across growth plate</td>
</tr>
<tr>
<td>IV (Through and through)*</td>
<td>Through epiphysis and metaphysis</td>
<td>Closed reduction and cast if anatomic; otherwise ORIF</td>
</tr>
<tr>
<td>V (Ramp)*</td>
<td>Crush injury of growth plate</td>
<td>High incidence of growth arrest; no specific treatment</td>
</tr>
</tbody>
</table>

* Types II–IV are more likely to cause growth arrest and progressive deformity

### Slipped Capital Femoral Epiphysis

• type I Salter-Harris epiphyseal injury at proximal hip
• most common adolescent hip disorder, peak incidence at pubertal growth spurt
• risk factors: male, obese (#1 factor), hypothyroid (risk of bilateral involvement)

**Etiology**
- multifactorial
  • genetic: autosomal dominant, blacks > caucasians
  • cartilaginous physis hypertrophies too rapidly under growth hormone effects
  • sex hormone secretion, which stabilizes physis, has not yet begun
  • overweight: mechanical stress
  • trauma: causes acute slip

In SCFE, bilateral involvement occurs in about 25%
Ages 10-14, below associated with hypothyroidism

Clinical Features
- acute: sudden, severe pain with limp
- chronic (typically): groin and anterior thigh pain, may present with knee pain
  - positive Trendelenburg sign on affected side, due to weakened gluteal muscles
- tender over joint capsule
- restricted internal rotation, abduction, flexion
  - Whitman's sign: obligatory external rotation during passive flexion of hip
- clinical classification: stable vs. unstable (provides prognostic information)
  - unstable means patient cannot ambulate even with crutches

Investigations
- x-rays: AP, frog-leg, lateral radiographs both hips
  - posterior and medial slip
  - disruption of Klein’s line
  - AP view may be normal or show widened/lucent growth plate compared with opposite side

Treatment and Complications
- mild/moderate slip: stabilize physis with pins in current position
- severe slip: ORIF or pin physis without reduction and osteotomy after epiphyseal fusion
- complications: AVN (roughly half of unstable hips), chondrolysis (loss of articular cartilage, resulting in narrowing of joint space), pin penetration, premature OA, loss of ROM

Developmental Dysplasia of the Hip
- most common orthopedic disorder in newborns
- due to ligamentous laxity, muscular underdevelopment, and abnormal shallow slope of acetabular roof
- spectrum of conditions that lead to hip subluxation and dislocation
  - dislocated femoral head completely out of acetabulum
  - dislocatable head in socket
  - head subluxates out of joint when provoked
  - dysplastic acetabulum, more shallow and more vertical than normal
- painless (if painful suspect septic dislocation)

Physical Exam
- diagnosis is clinical
  - limited abduction of the flexed hip (<50-60°)
  - affected leg shortening results in asymmetry in skin folds and gluteal muscles, wide perineum
  - Barlow's test (for dislocatable hip)
    - flex hips and knees to 90° and grasp thigh
    - fully adduct hips, push posteriorly to try to dislocate hips
  - Ortolani's test (for dislocatable hip)
    - initial position as above but try to reduce hip with fingertips during abduction
    - positive test: palpable clunk is felt (not heard) if hip is reduced
  - Galeazzi's sign
    - knees at unequal heights when hips and knees flexed
    - dislocated hip on side of lower knee
    - difficult test if child <1 yr
    - Trendelenburg test and gait useful if older (>2 yr)

Investigations
- U/S in first few months to view cartilage (bone is not calcified in newborns until 4-6 mo)
- follow up radiograph after 3 mo
- x-ray signs: false acetabulum, acetabular index >25°, broken Shenton's line, femoral neck above Hilgenreiner's line, ossification center outside of inner lower quadrant (quadrants formed by intersection of Hilgenreiner's and Perkin's line)

Treatment and Complications
- 0-6 mo: reduce hip using Pavlik harness to maintain abduction and flexion
- 6-18 mo: reduction under GA, hip spica cast x 2-3 mo (if Pavlik harness fails)
- >18 mo: open reduction; pelvic and/or femoral osteotomy
- complications
  - redislocation, inadequate reduction, stiffness
  - AVN of femoral head
Legg-Calvé-Perthes Disease (Coxa Plana)

- idiopathic AVN of femoral head, presents at 4-8 yr of age
- etiology unknown, 12% bilateral, M:F = 5:1, 1/1,200
- associations
  - family history
  - low birth weight
  - abnormal pregnancy/delivery
  - ADHD in 33% of cases, delayed bone age in 89%
- key features
  - AVN of proximal femoral epiphysis, abnormal growth of the physis, and eventual remodelling of regenerated bone

Clinical Features
- child with antalgic limp ± pain
- intermittent knee, hip, groin, or thigh pain
- flexion contracture (stiff hip): decreased internal rotation and abduction of hip

Investigations
- x-rays: AP pelvis, frog leg laterals
  - may be negative early (if high index of suspicion, move to bone scan or MRI)
  - eventually, characteristic collapse of femoral head (diagnostic)

Treatment
- goal is to preserve ROM and keep femoral head contained in acetabulum
- physiotherapy: ROM exercises
- brace in flexion and abduction x 2-3 yr (controversial)
- femoral or pelvic osteotomy (>8 yr of age or severe)
  - prognosis better in males, <5 yr, <50% of femoral head involved, abduction >30°
- 60% of involved hips do not require operative intervention
- Natural history is early onset OA and decreased ROM

Osgood-Schlatter Disease

Mechanism
- repetitive tensile stress on insertion of patellar tendon over the tibial tuberosity causes minor avulsion at the site and subsequent inflammatory reaction (tibial tubercle apophysitis)

Clinical Features
- tender lump over tibial tuberosity
- pain on resisted leg extension
- anterior knee pain exacerbated by jumping or kneeling, relieved by rest

Investigations
- x-rays: lateral knee: fragmentation of the tibial tubercle, ± ossicles in patellar tendon

Treatment
- benign, self-limited condition, does not resolve until growth halts
- may restrict activities such as basketball or cycling
- NSIADS, rest, flexibility, isometric strengthening exercises

Congenital Talipes Equinovarus (Club Foot)

Etiology
- intrinsic causes (neurologic, muscular, or connective tissue diseases) vs. extrinsic (intrauterine growth restriction), may be idiopathic, neurogenic, or syndrome-associated
- fixed deformity
- 3 parts to deformity
  - talipes: talus is inverted and internally rotated
  - equinus: ankle is plantar flexed
  - varus: heel and forefoot are in varus (supinated)
- 1-2/1,000 newborns, 50% bilateral, occurrence M:F, severity F>M

Physical Exam
- examine hips for associated DDH
- examine knees for deformity
- examine back for dysraphism (unfused vertebral bodies)
**Scoliosis**

**Definition**
- lateral curvature of spine with vertebral rotation

**Epidemiology**
- age: 10-14 yr
- more frequent and more severe in females

**Etiology**
- idiopathic: most common (90%)
- congenital: vertebrae fail to form or segment
- neuromuscular: UMN or LMN lesion, myopathy
- postural: leg length discrepancy, muscle spasm
- other: osteochondrodystrophies, neoplastic, traumatic

**Clinical Features**
- ± back pain
- 1° curve where several vertebrae affected
- 2° curves above and below fixed 1° curve to try and maintain normal position of head and pelvis
- asymmetric shoulder height when bent forward
- Adam's test: rib hump when bent forward
- prominent scapulae, creased flank, asymmetric pelvis
- associated posterior midline skin lesions in neuromuscular scolioses
  - café-au-lait spots, dimples, neurofibromas
  - axillary freckling, hemangiomas, hair patches
- associated pes cavus or leg atrophy
- apparent leg length discrepancy

**X-Rays**
- 3-foot standing, AP, lateral
  - measure curvature: Cobb angle
  - may have associated kyphosis

**Treatment**
- based on Cobb angle
  - <25°: observe for changes with serial radiographs
  - >25° or progressive: bracing (many types) that halt/slow curve progression but do NOT reverse deformity
  - >45°, cosmetically unacceptable or respiratory problems: surgical correction (spinal fusion)

---

**Bone Tumors**

- primary bone tumors are rare after 3rd decade
- metastases to bone are relatively common after 3rd decade

Adapted from: Buckholz RW, Heckman JD. Rockwood and Green’s Fractures in Adults. Volume 1. Philadelphia: Lippincott Williams & Wilkins, 2001; 558

---

**Figure 55. Cobb angle** — used to monitor the progression of the scoliotic curve

**Figure 56. Codman’s triangle** — a radiographic finding in malignancy, where the partially ossified periosteum is lifted off the cortex by neoplastic tissue
Diagnosis
• pain, swelling, tenderness, rarely regional adenopathy
• routine x-ray findings
  ▪ location (which bone, diaphysis, metaphysis, epiphysis)
  ▪ size
  ▪ lytic/lucent vs. sclerotic
  ▪ involvement (cortex, medulla, soft tissue)
  ▪ matrix (radiolucent, radiodense or calcified)
  ▪ periosteal reaction
  ▪ margin (geographic vs. permeative)
  ▪ any pathological fracture
  ▪ soft tissue swelling
• malignancy is suggested by rapid growth, warmth, tenderness, lack of sharp definition
• staging should include
  ▪ blood work including liver enzymes
  ▪ CT chest
  ▪ bone scan
  ▪ bone biopsy
    † should be referred to specialized center prior to biopsy
    † classified into benign, benign aggressive, and malignant
  ▪ MRI of affected bone

Benign Active Bone Tumors

BONE-FORMING TUMORS

Osteoid Osteoma
• peak incidence in 2nd and 3rd decades, M:F = 2:1 (young males)
• proximal femur and tibia diaphysis most common locations
• not known to metastasize
• radiographic findings: small, round radiolucent nidus (<1 cm) surrounded by dense sclerotic bone ("bull’s-eye")
• symptoms: produces severe intermittent pain from prostaglandin secretion and COX1/2 expression, mostly at night (diurnal prostaglandin production), thus is characteristically relieved by NSAIDs
• treatment: NSAIDs for night pain; surgical resection of nidus

FIBROUS LESIONS

Fibrous Cortical Defect
• occur in as many as 35% of children, peak incidence between 2-20 yr old, higher prevalence in males
• femur and proximal tibia most common locations, 50% of patients have multiple defects usually bilateral, symmetrical
• radiographic findings: diagnostic, metaphyseal eccentric ‘bubbly’ lytic lesion near physis; thin smooth/lobulated well-defined sclerotic margin
• treatment: most lesions resolve spontaneously

Osteochondroma
• 2nd and 3rd decades, M:F = 1.8:1
• most common of all benign bone tumors – 45%
• metaphysis of long bone near tendon attachment sites (usually distal femur, proximal tibia, or proximal humerus)
  ▪ radiographic findings: cartilage-capped bony spur on surface of bone ("mushroom" on x-ray)
  ▪ may be multiple (hereditary, autosomal dominant form) – higher risk of malignant change
  ▪ generally very slow growing and asymptomatic unless impinging on neurovascular structure (‘painless mass’)
  ▪ growth usually ceases when skeletal maturity is reached
• malignant degeneration occurs in 1-2% (becomes painful or rapidly grows)

Enchondroma
• 2nd and 3rd decades
• 60% occur in the small tubular bones of the hand and foot; others in femur (20%), humerus, ribs
• benign cartilagenous growth, an abnormality of chondroblasts, develops in medullary cavity
  ▪ single/multiple enlarged rarefied areas in tubular bones
  ▪ lytic lesion with sharp margination and central calcification

Figure 57. T1 MRI of femoral enchondroma
Figure 58. X-ray of aneurysmal bone cyst. Note the aggressive destruction of bone
malignant degeneration to chondrosarcoma occurs in 1-2% (pain in absence of pathologic fracture is an important clue)
not known to metastasize

CYSTIC LESIONS

Unicameral/Solitary Bone Cyst
• most common cystic lesion
• children and young adults, peak incidence during first 2 decades, M:F = 2:1
• proximal humerus and femur most common
• symptoms: asymptomatic, or local pain; complete pathological fracture (50% presentations) or incidental detection
• radiographic findings: lytic translucent area on metaphyseal side of growth plate, cortex thinned/expanded; well defined lesion
• treatment: aspiration followed by steroid injection; curettage ± bone graft indicated if re-fracture likely

Benign Aggressive Bone Tumors

Giant Cell Tumors/Aneurysmal Bone Cyst/Osteoblastoma
• affects patients of skeletal maturity, peak 3rd decade
• osteoblastoma: found in the distal femur, proximal tibia, distal radius, sacrum, tarsal bones, spine
• giant cell tumor: pulmonary metastases in 3%
• aneurysmal bone cysts: either solid with fibrous/granular tissue, or blood-filled
• radiographic findings
  • giant cell tumor: eccentric lytic lesions, in epiphyses adjacent to subchondral bone; may break through cortex; T2 MRI enhances fluid within lesion (hyper-intense signal)
  • aneurysmal bone cyst: expanded with honeycomb shape
  • osteoblastoma: often nonspecific; calcified central nidus (>2 cm) with radiolucent halo and sclerosis
• symptoms: local tenderness and swelling, pain may be progressive (giant cell tumors), ± symptoms of nerve root compression (osteoblastoma)
• 15% recur within 2 yr of surgery

Treatment
• intralesional curettage + bone graft or cement
• wide local excision of expendable bones

Malignant Bone Tumors

Table 26. Most Common Malignant Tumor Types for Age

<table>
<thead>

</tr>
</tbody>
</table>

Osteosarcoma
• most frequently diagnosed in 2nd decade of life (60%), 2nd most common primary malignancy in adults
• history of Paget's disease (elderly patients), previous radiation treatment
• predilection for sites of rapid growth: distal femur (45%), proximal tibia (20%), and proximal humerus (15%)
  • invasive, variable histology; frequent metastases without treatment (lung most common)
• painful symptoms: progressive pain, night pain, poorly defined swelling, decreased ROM
• radiographic findings:
  • characteristic periosteal reaction: Codman's triangle (see Figure 56) or "sunburst” spicule formation (tumor extension into periosteum)
  • destructive lesion in metaphysis may cross epiphyseal plate
• management: complete resection (limb salvage, rarely amputation), neo-adjuvant chemo; bone scan – rule out skeletal metastases, CT chest – rule out pulmonary metastases
• prognosis: 70% (high-grade); 90% (low-grade)
Chondrosarcoma  (see Figure 60)
- primary (2/3 cases)
  - patient >40 yr; previous normal bone expands into cortex to give pain, pathological fracture, flecks of calcification
- secondary (1/3 cases)
  - malignant degeneration of pre-existing cartilage tumor such as enchondroma or osteochondroma
  - younger age group and better prognosis than primary chondrosarcoma
  - symptoms: progressive pain, uncommonly palpable mass
  - radiographic findings: in medullary cavity, irregular “popcorn” calcification
  - treatment: unresponsive to chemotherapy, treat with aggressive surgical resection + reconstruction; regular follow-up x-rays of resection site and chest
  - prognosis: 10 yr survival 90% low-grade, 20-40% high-grade

Ewing’s Sarcoma
- most occur between 5-25 yr old
- florid periosteal reaction in metaphyses of long bone with diaphyseal extension
- metastases frequent without treatment
- signs/symptoms: presents with pain, mild fever, erythema and swelling, anemia, increased WBC, ESR, LDH (mimics an infection)
- radiographic findings: moth-eaten appearance with periosteal lamellated pattern (“onion-skinning”)
- treatment: resection, chemotherapy, radiation
- prognosis – 70%, worst prognostic factor is distant metastases

Multiple Myeloma
- most common primary malignant tumor of bone in adults (~43%)
- 90% occur in people >40 yr old, M:F = 2:1, African-Americans (twice as common)
- signs/symptoms: bone pain (cardinal early symptom), compression/pathological fractures, renal failure, nephritis, high incidence of infections (e.g. pyelonephritis/pneumonia), systemic (weakness, weight loss, anorexia)
- labs: anemia, thrombocytopenia, increased ESR, hypercalcemia
- radiographic findings: multiple, “punched-out” well-demarcated lesions, no surrounding sclerosis, marked bone expansion
- diagnosis
  - serum/urine immunoelectrophoresis (monoclonal gammopathy)
  - CT-guided biopsy of lytic lesions at multiple bony sites
- treatment: chemotherapy, bisphosphonates, radiation, surgery for symptomatic lesions or impending fractures – debulking, internal fixation
- prognosis: most 3 yr after diagnosis
- see Hematology: H49

Bone Metastases
- 2/3 from breast or prostate; also consider thyroid, lung, kidney
- usually osteolytic; prostate occasionally osteoblastic
- bone scan for MSK involvement, MRI for spinal involvement may be helpful
- stabilization of impending fractures
  - internal fixation, IM rods
  - bone cement

Figure 9. Anatomy of the neck
Anatomical Triangles of the Neck

Anterior triangle:
- bounded by anterior border of SCM, midline of neck, and lower border of mandible
- divided into
  - submental triangle: bounded by both anterior bellies of digastric and hyoid bone
  - digastric triangle: bounded by anterior and posterior bellies of digastric, and inferior border of mandible
  - carotid triangle: bounded by sternocleidomastoid, anterior belly of omohyoid, and posterior belly of digastric
    - contains: tail of parotid, submandibular gland, hypoglossal nerve, carotid bifurcation, and lymph nodes

Posterior triangle
- bounded by posterior border of sternocleidomastoid, anterior border of trapezius, and middle third of clavicle
- divided into
  - occipital triangle: superior to posterior belly of the omohyoid
  - subclavian triangle: inferior to posterior belly of omohyoid
- contains: spinal accessory nerve and lymph nodes

*Virchow node: left lower jugular (level IV) supraclavicular node
**Includes some supraclavicular nodes
***Includes pretracheal, pretracheal, paratracheal, and parathyroidal nodes

--

Paired Parasympathetic Ganglia of the Head and Neck
- Ciliary: pupillary constriction
- Pterygopalatine: lacrimal gland, nasal mucosa
- Submandibular: submandibular, sublingual glands
- Otic: parotid gland

Function of Facial Nerve
“Ears, Tears, Face, Taste”
Ears: stapedius muscle
Tears: lacrimation (lacrimal gland) and salivation (parotid)
Face: muscles of facial expression
Taste: sensory anterior 2/3 of tongue (via chorda tympani)

4 Strap Muscles of the Neck
- Thyrohyoid
- Omohyoid
- Sternohyoid
- Sternothyroid

![Figure 10. Anatomy of the thyroid gland](image-url)
**Differential Diagnoses of Common Presenting Problems**

### Dizziness

**True Vertigo**
- Benign paroxysmal positional vertigo (BPPV)
- Vestibular neuritis
- Meniere's disease
- Autoimmune inner ear disease
- Cholesteatoma
- Ototoxic drug exposure
- Perilymph fistula
- Recurrent vestibulopathy
- Superior semicircular canal dehiscence
- Temporal bone fracture

**Non-Vertiginous**
- Anemia
- Cardiac
- Aortic stenosis
- Arrhythmias
- Orthostatic hypotension
- Peripheral neuropathy
- Vasovagal
- Visual impairment

**Organic Diseases**
- Migrainous vertigo
- Multiple sclerosis
- Inflammation
- Cerebellar abscess
- Meningitis
- Toxic: alcohol, hypnotics, drugs
- Trauma: cerebellar contusion
- Tumours
- CPA tumors
- Glomus tumors
- Posterior fossa tumour

**Functional**
- Anxiety
- Depression
- Panic disorder
- Personality disorder
- Phobic dizziness

---

*True nystagmus and vertigo caused by a peripheral lesion will never last longer than a couple of weeks because of compensation. Central lesions do not compensate, hence nystagmus and vertigo will persist.*

*5 "D’s of Vertebrobasilar Insufficiency*
- Drop attacks
- Diplopia
- Dysarthria
- Dizziness
- Dysphagia

---

### Otalgia

**External Ear**
- Infection
  - Auricular cellulitis
  - External canal abscess
  - Herpes simplex/zoster
  - Otis externa
- Trauma
  - Burns
  - Frostbite
  - Hematoma
  - Lacerations
- Other
  - Cerumen impaction
  - Foreign body
  - Neoplasm of external canal

**Middle/Inner Ear**
- Infection
  - ADOM
  - Mastoiditis
  - Myringitis
  - Otitis media with effusion
  - Skull base infections
- Trauma
  - Barotrauma
  - Traumatic perforation
- Other
  - Cholesteatoma
  - Neoplasm
  - Wegener's granulomatosis

**Referred Pain**
- Infection
  - Ramsay Hunt syndrome
  - Tonsillitis
  - Tracheitis
  - Trauma
  - Cervical arthritis
  - Thyroiditis
- Other
  - Glossopharyngeal neuralgia
  - Neoplasm of oral cavity, larynx, pharynx
  - Teeth
  - TMJ syndrome
  - Trismus

|• Laryngeal atresia                             |                                |
Neck Mass

Figure 15. Differential diagnosis of a neck mass

Normal Hearing Physiology

- **Conductive pathway (external auditory canal to cochlea):** air conduction of sound energy down the EAC $\rightarrow$ vibration of the tympanic membrane (area effect) $\rightarrow$ sequential vibration of the middle ear ossicles: malleus, incus, stapes (lever effect) $\rightarrow$ transmission of amplified vibrations from the stapes footplate in the middle ear to the oval window of the cochlea in the inner ear $\rightarrow$ pressure differential on cochlear fluid creates movement along the basilar membrane within the cochlea from base to apex
- **Neural pathway (nerve to brain):** basilar membrane vibration stimulates overlying hair cells in the organ of Corti $\rightarrow$ stimulation of bipolar neurons in the spiral ganglion of the cochlear division of CN VIII $\rightarrow$ cochlear nucleus $\rightarrow$ superior olivary nucleus $\rightarrow$ lateral lemniscus $\rightarrow$ inferior colliculus $\rightarrow$ Sylvian fissure of temporal lobe

Types of Hearing Loss

1. **Conductive Hearing Loss**
   - conduction of sound to the cochlea is impaired
   - can be caused by external and middle ear disease

2. **Sensorineural Hearing Loss**
   - due to a defect in the conversion of sound into neural signals or in the transmission of those signals to the cortex
   - can be caused by disease of the inner ear (cochlea), acoustic nerve (CN VIII), brainstem, or cortex

3. **Mixed Hearing Loss**
   - combination of conductive and sensorineural hearing loss

Auditory Acuity

- whispered-voice test: mask one ear and whisper into the other
- tuning fork tests (see Table 4; audiogram is of greater utility)
- sensitivity depends on which tuning fork used (256 Hz, 512 Hz, 1024 Hz; 512 Hz has greatest sensitivity)
  - Rinne test
    - 512 Hz tuning fork is struck and held firmly on mastoid process to test BC; the tuning fork is then placed beside the pinna to test AC
    - If AC > BC $\rightarrow$ positive Rinne (normal)
  - Weber test
    - 512 Hz tuning fork is held on vertex of head and patient states whether it is heard centrally (Weber negative) or is lateralized to one side (Weber right, Weber left)
    - can place vibrating fork on patient's chin while they clench their teeth, or directly on teeth to elicit more reliable response
    - will only lateralize if difference in hearing loss between ears is $\geq 6$ dB

Order of the Neural Pathway (with Corresponding Waves on ABR)
- E CO LI
- Eighth cranial nerve (I – II)
- Cochlear nucleus (III)
- Superior olivary nucleus
- Lateral lemniscus (IV – V)
- Inferior colliculus

Weber Test Lateralization = ipsilateral conductive hearing loss or contralateral sensorineural hearing loss

The Weber test is more sensitive in detecting conductive hearing loss than the Rinne test

HL = Intensity x Duration
Table 4. The Interpretation of Tuning Fork Tests

<table>
<thead>
<tr>
<th>Examples</th>
<th>Weber</th>
<th>Rinne</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Right-sided severe sensorineural hearing loss or dead right ear, normal left ear</td>
<td>Lateralizes to left</td>
<td>BC&gt;AC (−) right*</td>
</tr>
</tbody>
</table>

*A vibrating tuning fork on the mastoid stimulates the cochlea bilaterally, therefore in this case the left cochlea is stimulated by the Rinne test on the right (e.g., a false negative test). These tests are not valid if the ear canals are obstructed with cerumen (e.g., will create conductive loss).

Pure Tone Audiometry

- a threshold is the lowest intensity level at which a patient can hear the tone 50% of the time
- thresholds are obtained for each ear at frequencies of 250, 500, 1000, 2000, 4000, and 8000 Hz
- air conduction thresholds are obtained with headphones and measure outer, middle, inner ear, and auditory nerve function
- bone conduction thresholds are obtained with bone conduction oscillators which bypass the outer and middle ear

Degree of Hearing Loss

- determined on basis of the pure tone average (PTA) at 500, 1000, and 2000 Hz

**Frequency of Tuning Fork (Hz)** | **Minimum Hearing Loss for Rinne to Reverse (BC>AC, NEGATIVE Rinne) (dB)**
---|---
256 | 15
512 | 30
1024 | 45

Range of Frequencies Audible to Human Ear

- 20 to 20000 Hz
- Most sensitive frequencies: 1000 to 4000 Hz
- Range of human speech: 500 to 2000 Hz

Hearing loss most often occurs at higher frequencies. Noise-induced (occupational) HL is seen at 4000 Hz. HL associated with otosclerosis is seen at 2000 Hz (Carhart’s notch)

Air conduction thresholds can only be equal to or worse than bone conduction thresholds

Speech Audiometry

Speech Reception Threshold
- lowest hearing level at which patient is able to repeat 50% of two syllable words which have equal emphasis on each syllable (spondee words)
- SRT and best pure tone threshold in the 500 to 2000 Hz range (frequency range of human speech) usually agree within 5 dB; if not, suspect a retrocochlear lesion or functional hearing loss
- used to assess the reliability of the pure tone audiometry

Speech Discrimination Test
- percentage of words the patient correctly repeats from a list of 50 monosyllabic words
- tested at 40 dB above the patient’s SRT, therefore degree of hearing loss is taken into account
- patients with normal hearing or conductive hearing loss score >90%
- score depends on extent of SNHL
- rollover effect: a decrease in discrimination as sound intensity increases; typical of a retrocochlear lesion (e.g. acoustic neuroma)
- investigate further if scores differ more than 20% between ears as asymmetry may indicate a retrocochlear lesion
- used as best predictor of hearing aid response: a poor discrimination score indicates significant neural degeneration and hearing aids may not be the best option for the patient

Impedance Audiometry

Tympanogram
- the Eustachian tube equalizes the pressure between the external and middle ear
- tympanograms graph the compliance of the middle ear system against a pressure gradient ranging from to –400 to +200 mmH2O
- tympanogram peak occurs at the point of maximum compliance: where the pressure in the external canal is equivalent to the pressure in the middle ear
- normal range: –100 to +50 mmH2O

- High
  - Type A
    - Normal pressure peak at 0
    - Note: with otosclerosis, peak is still at 0 mmH2O but has a lower amplitude
    - Note: with ossicular chain discontinuity, peak is still at 0 mmH2O but has a higher amplitude
  - Type B
    - No pressure peak
  - Type C
    - Negative pressure peak

- Low

Figure 17. Tympanograms

Static Compliance
- volume measurement reflecting overall stiffness of the middle ear system
- normal range: 0.3-1.6 cc
- negative middle ear pressure and abnormal compliance indicate middle ear pathology
- in a type B curve, ear canal volumes of >2 cc in children and 2.5 cc in adults indicate TM perforation or presence of a patent ventilation tube

Acoustic Stapedial Reflexes
- stapedius muscle contracts in response to loud sound
- **acoustic reflex threshold** = 70-100 dB greater than hearing threshold; if hearing threshold >85 dB, reflex likely absent
- stimulating either ear causes bilateral and symmetrical reflexes
- for reflex to be present, CN VII must be intact and no conductive hearing loss in monitored ear
- if reflex is absent without conductive or severe sensorineural loss, suspect CN VII lesion
- **acoustic reflex decay test** = ability of stapedius muscle to sustain contraction for 10 s at 10 dB
- normally, little reflex decay occurs at 500 and 1000 Hz
- with cochlear hearing loss, acoustic reflex thresholds are 25-60 dB
- with retrocochlear hearing loss (acoustic neuroma), absent acoustic reflexes or marked reflex decay (>50%) within 5 s
**Auditory Brainstem Response**

- measures neuroelectric potentials (waves) in response to a stimulus in five different anatomic sites (see Order of Neural Pathway sidebar on OT9); this test can be used to determine the site of lesion
- delay in brainstem response suggests cochlear or retrocochlear abnormalities
- does not require volition or co-operation of patient (therefore of value in children and in malingerers)

**Otoacoustic Emissions**

- objective test of hearing where a series of clicks is presented to the ear and the cochlea generates an echo which can be measured
- often used in newborn screening
- can be used to uncover normal hearing in malingering patients
- absence of emissions can be due to hearing loss or fluid in the middle ear

**Aural Rehabilitation**

- dependent on degree of hearing loss, communicative requirements, motivation, expectations, and physical and mental abilities
- negative prognostic factors
  - poor speech discrimination
  - narrow dynamic range (recruitment)
  - unrealistic expectations
- types of hearing aids
  - BTE: behind-the-ear (with occlusive mold or open fit which allows natural sound to pass – for milder hearing losses)
  - ITE: in-the-ear, placed in concha
  - ITC: in-the-canal, placed entirely in ear canal
  - CIC: contained-in-canal, placed deeply in ear canal
  - bone conduction – bone-anchored hearing aid (BAHA): attached to the skull
  - contralateral routing of signals (CROS)
- assistive listening devices
  - direct/indirect audio output
  - infrared, FM radio, or induction loop systems
  - telephone, television, or alerting devices
- cochlear implants
  - electrode is inserted into the cochlea to allow direct stimulation of the auditory nerve
  - for profound bilateral sensorineural hearing loss not rehabilitated with conventional hearing aids
  - established indication: post-lingually deafened adults, pre- and post-lingually deaf children

**Vertigo**

**Evaluation of the Dizzy Patient**

- vertigo: illusion of rotational, linear, or tilting movement of self or environment
  - vertigo is produced by peripheral (inner ear) or central (brainstem-cerebellum) stimulation
- it is important to distinguish vertigo from other disease entities that may present with similar complaints of “dizziness” (e.g. cardiovascular, psychiatric, neurological, aging)

Benign Paroxysmal Positional Vertigo

Definition
- acute attacks of transient rotatory vertigo lasting **seconds to minutes** initiated by certain head positions, accompanied by torsional (i.e. rotatory) nystagmus (geotropic = fast phase towards the floor)
- most common form of positional vertigo (50% of patients with peripheral vestibular dysfunction)

Etiology
- due to canalithiasis (migration of free floating otoliths within the endolymph of the semicircular canal) or cupulolithiasis (otolith attached to the cupula of the semicircular canal)
  - can affect each of the 3 semicircular canals, posterior canal is affected in >90% of cases
  - causes: head injury, viral infection (URTI), degenerative disease, idiopathic
  - results in slightly different signals being received by the brain from the two balance organs resulting in sensation of movement

Diagnosis
- history (time course, provoking factors, associative symptoms)
- positive Dix-Hallpike maneuver (sensitivity 82%, specificity 71%)

Dix-Hallpike Positional Testing (see website for video and illustrations)
- the patient is rapidly moved from a sitting position to a supine position with the head hanging over the end of the table, turned to one side at 45° and neck extended 20° holding the position for 20 s
- onset of vertigo and rotary nystagmus indicate a positive test for the dependent side
- other diagnostic testing is not indicated in posterior canal BPPV

Treatment
- reassure patient that process resolves spontaneously
- particle repositioning maneuvers
  - Epley maneuver (performed by MD)
  - Brandt-Daroff exercises (performed by patient)
- surgery for refractory cases
- anti-emetics for nausea/vomiting
- drugs to suppress the vestibular system delay eventual recovery and are therefore not used

Menière’s Disease (Endolymphatic Hydrops)

Definition
- episodic attacks of tinnitus, hearing loss, aural fullness, and vertigo lasting **minutes to hours**

Proposed Etiology
- inadequate absorption of endolymph leads to endolymphatic hydrops (over accumulation) that distorts the membranous labyrinth

Diagnostic Criteria for Menière’s Disease (must have all three)
- Two spontaneous episodes of rotational vertigo ≥20 min
- Audiometric confirmation of SNHL (often low frequency)
- Tinnitus and/or aural fullness
Epidemiology
- peak incidence 40-60 yr
- bilateral in 35% of cases

Clinical Features
- episodic vertigo, fluctuating low frequency SNHL, tinnitus, and aural fullness
- ± drop attacks (Tumarkin crisis), ± N/V
- vertigo disappears with time (min to h), but hearing loss remains
- early in the disease: fluctuating SNHL
- later stages: persistent tinnitus and progressive hearing loss
- attacks come in clusters and can be debilitating to the patient
- triggers: high salt intake, caffeine, stress, nicotine, and alcohol

Treatment
- acute management may consist of bed rest, antiemetics, antivertiginous drugs, and low molecular weight dextrans (not commonly used)
- long-term management may include:
  - medical
    - low salt diet, diuretics (e.g. hydrochlorothiazide, triamterene, amiloride)
    - antivertiginous drugs prophylactically to decrease intensity of attacks
    - local application of gentamicin to destroy vestibular end-organ, results in complete SNHL
  - surgical
    - selective vestibular neurectomy or transtympanic labyrinthectomy
    - vestibular implants have recently been introduced, experimentally
- must monitor opposite ear as bilaterality occurs in 35% of cases

Vestibular Neuronitis

Definition
- acute onset of disabling vertigo often accompanied by nausea, vomiting, and imbalance without hearing loss that resolves over days leaving a residual imbalance that lasts days to weeks

Etiology
- thought to be due to a viral (e.g. measles, mumps, herpes zoster) or post viral inflammatory condition
- ~30% of cases have associated URTI symptoms
- other: microvascular events, diabetes, autoimmune process
- considered to be the vestibular equivalent of Bell’s palsy, sudden hearing loss, and acute vocal cord palsy

Clinical Features
- acute phase
  - severe vertigo with nausea, vomiting, and imbalance lasting 1-5 d
  - irritative nystagmus (fast phase towards the offending ear)
  - patient tends to veer towards affected side
- convalescent phase
  - imbalance and motion sickness lasting days to weeks
  - spontaneous nystagmus away from affected side
  - gradual vestibular adaptation requires weeks to months
- incomplete recovery likely with the following risk factors: elderly, visual impairment, poor ambulation
- repeated attacks can occur

Treatment
- acute phase
  - bed rest, vestibular sedatives dimenhydrinate, diazepam
- convalescent phase
  - progressive ambulation especially in the elderly
  - vestibular exercises: involve eye and head movements, sitting, standing, and walking

Labyrinthitis

Definition
- acute infection of the inner ear resulting in vertigo and hearing loss

Etiology
- may be serous (viral) or purulent (bacterial)
- occurs as a complication of acute and chronic otitis media, bacterial meningitis, cholesteatoma, and temporal bone fractures
- bacterial: *S. pneumoniae*, *H. influenzae*, *M. catarrhalis*, *P. aeruginosa*, *P. mirabilis*
- viral: rubella, CMV, measles, mumps, varicella zoster

Drop Attacks (Tumarkin’s Otolithic Crisis) are sudden falls occurring without warning and without LOC
Before proceeding with gentamicin treatment, perform a gadolinium enhanced MRI to rule out CPA tumor as the cause of symptoms
Clinical Features
• sudden onset of vertigo, N/V, tinnitus, and unilateral hearing loss with no associated fever or pain
• meningitis is a serious complication

Investigations
• CT head
• if meningitis is suspected: lumbar puncture, blood cultures

Treatment
• treat with IV antibiotics, drainage of middle ear ± mastoidectomy

Acoustic Neuroma (Vestibular Schwannoma)

Definition
• schwannoma of the vestibular portion of CN VIII

Pathogenesis
• starts in the internal auditory canal and expands into cerebellopontine angle (CPA), compressing cerebellum and brainstem
• when associated with type 2 neurofibromatosis (NF2): bilateral acoustic neuromas, café-au-lait skin lesions, and multiple intracranial lesions

Clinical Features
• usually presents with unilateral SNHL (chronic) or tinnitus
• dizziness and unsteadiness may be present, but true vertigo is rare as tumor growth occurs slowly and thus compensation occurs
• facial nerve palsy and trigeminal (V1) sensory deficit (corneal reflex) are late complications
• risk factors: exposure to loud noise, childhood exposure to low-dose radiation, history of parathyroid adenoma

Diagnosis
• MRI with gadolinium contrast (gold standard)
• audiogram (to assess SNHL)
• poor speech discrimination relative to the hearing loss
• stapedial reflex absent or significant reflex decay
• ABR: increase in latency of the 5th wave
• vestibular tests: normal or asymmetric caloric weakness (an early sign)

Treatment
• expectant management if tumor is very small, or in elderly
• definitive management is surgical excision
• other options: gamma knife, radiation

Tinnitus

Definition
• an auditory perception in the absence of an acoustic stimuli, likely related to loss of input to neurons in central auditory pathways and resulting in abnormal firing

History
• subjective vs. objective (Figure 14, OT7)
• continuous vs. pulsatile (vascular in origin)
• unilateral vs. bilateral
• associated symptoms: hearing loss, vertigo, aural fullness, otalgia, otorrhea

Investigations
• audiology
• if unilateral
  • ABR, gadolinium enhanced MRI to exclude a retrocochlear lesion
  • CT to diagnose glomus tympanicum (rare)
• MRI or angiogram to diagnose AVM
• if suspect metabolic abnormality: lipid profile, TSH

Treatment
• if a cause is found, treat the cause (e.g. drainage of middle ear effusion, embolization or excision of AVM)
• with no treatable cause: 50% will improve, 25% worsen, 25% remain the same
• avoid loud noise, ototoxic meds, caffeine, smoking
• tinnitus clinics
• identify situations where tinnitus is most bothersome (e.g. quiet times), mask tinnitus with soft music or “white noise”
• hearing aid if coexistent hearing loss
• tinnitus instrument: combines hearing aid with white noise masker
• trial of tocainamide

Diseases of the External Ear

Cerumen Impaction

Etiology
• ear wax: a mixture of secretions from ceruminous and pilosebaceous glands, squames of epithelium, dust, and debris

Risk Factors
• hairy or narrow ear canals, in-the-ear hearing aids, cotton swab usage, osteomata

Clinical Features
• hearing loss (conductive)
• ± tinnitus, vertigo, otalgia, aural fullness

Treatment
• ceruminolytic drops (bicarbonate solution, olive oil, glycerine, Cerumenex®)
• syringing
• manual debridement (by MD)

Exostoses

Definition
• bony protuberances in the external auditory canal composed of lamellar bone

Etiology
• possible association with swimming in cold water

Clinical Features
• usually an incidental finding
• if large, they can cause cerumen impaction or otitis externa

Treatment
• no treatment required unless symptomatic

Otitis Externa

Etiology
• bacteria (~90% of OE): Pseudomonas aeruginosa, Pseudomonas vulgaris, E. coli, S. aureus
• fungus: Candida albicans, Aspergillus niger

Risk Factors
• associated with swimming (“swimmer’s ear”)
• mechanical cleaning (Q-tips®), skin dermatitis, aggressive scratching
• devices that occlude the ear canal: hearing aids, headphones, etc.
• allergic contact dermatitis, dermatologic conditions (psoriasis, atopic dermatitis)

Clinical Features
• acute
  ▪ pain aggravated by movement of auricle (traction of pinna or pressure over tragus)
  ▪ otorrhea (sticky yellow purulent discharge)
  ▪ conductive hearing loss ± aural fullness 2nd to obstruction of external canal by swelling and purulent debris
  ▪ posterior auricular lymphadenopathy
  ▪ complicated OE exists if the pinna and/or the periauricular soft tissues are erythematos and swollen
• chronic
  ▪ pruritus of external ear ± excoriation of ear canal
  ▪ atrophic and scaly epidermal lining, ± otorrhea, ± hearing loss
  ▪ wide meatus but no pain with movement of auricle
  ▪ tympanic membrane appears normal
**Treatment**
- clean ear under magnification with irrigation, suction, dry swabbing, and C&S
- bacterial etiology
  - antipseudomonal otic drops (e.g. ciprofloxacin) or a combination of antibiotic and steroid (e.g. Cipro HC®)
  - do not use aminoglycoside if the tympanic membrane (TM) is perforated because of the risk of ototoxicity
  - introduction of fine gauze wick (pope wick) if external canal edematous
  - ± 3% acetic acid solution to acidify ear canal (low pH is bacteriostatic)
  - systemic antibiotics if either cervical lymphadenopathy or cellulitis is present
- fungal etiology
  - repeated debridement and topical antifungals (gentian violet, Mycostatin® powder, boric acid, cloquinol-flumetasone drops)
  - ± analgesics
- ± analgesics
- ± corticosteroid alone (e.g. diprosalic acid)

**Malignant (Necrotizing) Otitis Externa (Skull Base Osteomyelitis)**

**Definition**
- osteomyelitis of the temporal bone

**Epidemiology**
- occurs in elderly diabetics and immunocompromised patients

**Etiology**
- rare complication of otitis externa
- *Pseudomonas* infection in 99% of cases

**Clinical Features**
- otalgia and purulent otorrhea that is refractory to medical therapy
- granulation tissue on the floor of the auditory canal

**Complications**
- cranial nerve palsy (most commonly VII>X>XI)
- systemic infection, death

**Management**
- imaging: high resolution temporal bone CT scan, gadolinium enhanced MRI, technetium scan
- requires hospital admission, debridement, IV antibiotics, hyperbaric O₂
- may require OR for debridement of necrotic tissue/bone

**Gallium and Technetium Scans**

Gallium scans are used to show sites of active infection. Gallium is taken up by PMNs and therefore only lights up when active infection is present. It will not show the extent of osteomyelitis. Technetium scans provide information about osteoblastic activity and as such are used to demonstrate sites of osteomyelitis. Technetium scans help with diagnosis whereas gallium scans are useful in follow-up

**Diseases of the Middle Ear**

**Acute Otitis Media and Otitis Media with Effusion**

- see *Pediatric Otolaryngology, OT39*

**Chronic Otitis Media**

**Definition**
- an ear with TM perforation in the setting of recurrent or chronic ear infections

**Benign**
- dry TM perforation without active infection

**Chronic Serous Otitis Media**
- continuous serous drainage (straw-colored)

**Chronic Suppurative Otitis Media**
- persistent purulent Otitis through a perforated TM
**Cholesteatoma**

**Definition**
- a cyst composed of keratinized desquamated epithelial cells occurring in the middle ear, mastoid, and temporal bone
- two types: congenital and acquired

**Congenital**
- presents as a “small white pearl” behind an intact tympanic membrane (anterior and medial to the malleus) or as a conductive hearing loss
- believed to be due to aberrant migration of external canal ectoderm during development
- not associated with otitis media/Eustachian tube dysfunction

**Acquired (more common)**
- generally occurs as a consequence of otitis media and chronic Eustachian tube dysfunction
- primary cholesteatoma
  - frequently associated with retraction pockets in the pars flaccida (may lead to attic cholesteatomas which are difficult to visualize)
  - often has crusting or desquamated debris on lateral surface
- secondary cholesteatoma
  - pearly mass evident behind TM, frequently associated with marginal perforation
  - may appear as skin that have replaced the mucosa of the middle ear
- the associated chronic inflammatory process causes progressive destruction of surrounding bony structures

**Clinical Features**
- history of otitis media (especially if unilateral), ventilation tubes, ear surgery
- symptoms
  - progressive hearing loss (predominantly conductive although may get sensorineural hearing loss in late stage)
  - otalgia, aural fullness, fever
- signs
  - retraction pocket in TM, may contain keratin debris
  - TM perforation
  - granulation tissue, polyp visible on otoscopy
  - malodorous, unilateral otorrhea

**Complications**
- Table 8. Complications of Cholesteatoma
<table>
<thead>
<tr>
<th>Local</th>
<th>Intracranial</th>
</tr>
</thead>
<tbody>

<td>Sigmoid sinus thrombosis</td>
</tr>
<tr>
<td>Temporal bone infection: mastoiditis, petrositis</td>
<td>Intracranial abscess (subdural, epidural, cerebellar)</td>
</tr>
</tbody>
</table>

**Investigations**
- audiogram and CT scan

**Treatment**
- there is no conservative therapy for cholesteatoma
- surgical: mastoidectomy ± tympanoplasty ± ossicular reconstruction

**Mastoiditis**

**Definition**
- infection (usually subperiosteal) of mastoid air cells, most commonly seen approximately two weeks after onset of untreated or inadequately treated acute suppurative otitis media
- more common in children than adults

**Etiology**
- acute mastoiditis caused by the same organisms as AOM: *S. pneumoniae, H. influenzae, M. catarrhalis, S. pyogenes, S. aureus, P. aeruginosa*

**Clinical Features**
- otorrhea
- tenderness to pressure over the mastoid
- retroauricular swelling with protruding ear
- fever, hearing loss, ± TM perforation (late)
- CT radiologic findings: opacification of mastoid air cells by fluid and interruption of normal trabeculations of cells (coalescence)
Treatment
• IV antibiotics with myringotomy and ventilation tubes – usually all that is required acutely
• cortical mastoidectomy
  ▪ debridement of infected tissue allowing aeration and drainage
• indications for surgery
  ▪ failure of medical treatment after 48 h
  ▪ symptoms of intracranial complications
  ▪ aural discharge persisting for 4 wk and resistant to antibiotics

Otosclerosis
Definition
• fusion of stapes footplate to oval window so that it cannot vibrate

Etiology
• autosomal dominant, variable penetrance approximately 40%
• F>M, progresses during pregnancy (hormone responsive)

Clinical Features
• progressive conductive hearing loss first noticed in teens and 20s (may progress to sensorineural hearing loss if cochlea involved)
• ± pulsatile tinnitus
• tympanic membrane normal ± pink blush (Schwartz’s sign) associated with the neovascularization of otosclerotic bone
• characteristic dip at 2000 Hz (Carhart’s notch) on audiogram (Figure 16C, OT10)

Treatment
• monitor with serial audiograms if coping with loss
• hearing aid (air conduction, bone conduction, BAHA)
• stapedectomy or stapedotomy (with laser or drill) with prosthesis is definitive treatment

Otosclerosis is the 2nd most common cause of conductive hearing loss in 15-50 yr old (after cerumen impaction)

Diseases of the Inner Ear
Congenital Sensorineural Hearing Loss

Hereditary Defects
• non-syndrome associated (70%)
  ▪ often idiopathic, autosomal recessive
  ▪ connexin 26 (GJB2) most common
• syndrome associated (30%)
  ▪ Waardenburg: white forelock, heterochromia iridis (each eye different color), wide nasal bridge and increased distance between medial canthi
  ▪ Pendred: deafness associated with thyroid gland disorders, SLC26A4 gene, enlarged vestibular aqueducts
  ▪ Treacher-Collins: first and second branchial cleft anomalies
  ▪ Alport: hereditary nephritis

Prenatal TORCH Infections
• toxoplasmosis, others (e.g. HIV, syphilis), rubella, CMV, HSV

Perinatal
• Rh incompatibility
• anoxia
• hyperbilirubinemia
• birth trauma (hemorrhage into inner ear)

Postnatal
• meningitis, mumps, measles

High Risk Factors (for hearing loss in newborns)
• low birth weight/prematurity
• perinatal anoxia (low APGARs)
• kernicterus: bilirubin >25 mg/dL
• craniofacial abnormality
• family history of deafness in childhood
• 1st trimester illness: TORCH infections
• neonatal sepsis
• ototoxic drugs
perinatal infection, including post-natal meningitis
consanguinity
50-75% of newborns with SNHL have at least one of the above risk factors and 90% of these have spent time in the NICU
presence of any risk factor: ABR study performed before leaving NICU and at 3 mo adjusted age
early rehabilitation improves speech and school performance

### Presbycusis

**Definition**
- SNHL associated with aging (starting in 5th and 6th decades)

**Etiology**
- hair cell degeneration
- age related degeneration of basilar membrane, possibly genetic etiology
- cochlear neuron damage
- ischemia of inner ear

**Clinical Features**
- progressive, bilateral hearing loss initially at high frequencies, then middle frequencies
- loss of discrimination of speech especially with background noise present – patients describe people as mumbling
- recruitment phenomenon: inability to tolerate loud sounds
- tinnitus

**Treatment**
- hearing aid if patient has difficulty functioning, hearing loss >30-35 dB, and good speech discrimination
- ± lip reading, auditory training, auditory aids (doorbell and phone lights)

### Sudden Sensorineural Hearing Loss

**Clinical Features**
- presents as a sudden onset of significant SNHL (usually unilateral) ± tinnitus, aural fullness
- usually idiopathic, rule out other causes
  - autoimmune causes (e.g. ESR, rheumatoid factor, ANA)
  - MRI to rule out tumor and/or CT to rule out ischemic/hemorrhagic stroke if associated with any other focal neurological signs (e.g. vertigo, ataxia, abnormality of CN V or VII, weakness)

**Treatment**
- oral corticosteroids within 3 d of onset: prednisone 1 mg/kg/d for 10-14 d

**Prognosis**
- depends on degree of hearing loss
- 70% resolve within 10-14 d
- 20% experience partial resolution
- 10% experience permanent hearing loss

### Autoimmune Inner Ear Disease

**Etiology**
- idiopathic
- may be associated with systemic autoimmune diseases (e.g. rheumatoid arthritis, SLE), vasculitides (e.g. GPA, polyarteritis nodosa), and allergies

**Epidemiology**
- most common between ages 20-50

**Clinical Features**
- rapidly progressive or fluctuating bilateral SNHL
- ± tinnitus, aural fullness, vestibular symptoms (i.e. ataxia, disequilibrium, vertigo)

**Investigations**
- autoimmune workup: CBC, ESR, ANA, rheumatoid factor
Treatment
- high-dose corticosteroids: treat early for at least 30 d
- consider cytotoxic medication for steroid non-responders

Drug Ototoxicity

Aminoglycosides
- streptomycin and gentamicin (vestibulotoxic), kanamycin, and tobramycin (cochleotoxic)
- toxic to hair cells by any route: oral, IV, and topical (if the TM is perforated)
- destroys sensory hair cells: outer first, inner second (therefore otoacoustic emissions are lost first)
- high frequency hearing loss develops earliest
- ototoxicity occurs days to weeks post-treatment
- must monitor with peak and trough levels when prescribed, especially if patient has neutropenia and/or history of ear or renal problems
- q24h dosing recommended (with amount determined by creatinine clearance)
- aminoglycoside toxicity displays saturable kinetics, therefore, once daily dosing presents less risk than divided daily doses
- duration of treatment is the most important predictor of ototoxicity
- treatment: immediately stop aminoglycosides

Salicylates
- hearing loss with tinnitus, reversible if discontinued

Antimalarials (Quinines)
- hearing loss with tinnitus
- reversible if discontinued but can lead to permanent loss

Others
- many antineoplastic agents are ototoxic (weigh risks vs. benefits)
- loop diuretics

Noise-Induced Sensorineural Hearing Loss

Pathogenesis
- 85-90 dB over months or years or single sound impulses >135 dB can cause cochlear damage
- bilateral SNHL initially and most prominently at 4000 Hz (resonant frequency of the temporal bone), known as “boilermaker’s notch” on audiogram, extends to higher and lower frequencies with time (see Figure 16D, OT10)
- speech reception not altered until hearing loss >30 dB at speech frequency, therefore considerable damage may occur before patient complains of hearing loss
- difficulty with speech discrimination, especially in situations with competing noise

Phases of Hearing Loss
- dependent on: intensity of sound and duration of exposure
- temporary threshold shift
  - when exposed to loud sound, decreased sensitivity or increased threshold for sound
  - may have associated aural fullness and tinnitus
  - with removal of noise, hearing returns to normal
- permanent threshold shift
  - hearing does not return to previous state

Treatment
- hearing aid
- prevention
  - ear protectors: muffs, plugs
  - limit exposure to noise with frequent rest periods
  - regular audiologic follow-up

</tbody>
</table>

- characterized as longitudinal or transverse relative to the long axis of the petrous temporal bone
- temporal bone fractures are rarely purely transverse or longitudinal (often a mixed picture)

Diagnosis
- otoscopy
- do not syringe or manipulate external auditory meatus due to risk of inducing meningitis via TM perforation
- CT head
- audiometry, facial nerve tests (for transverse fractures), Schirmer’s test (of lacrimation), stapedial reflexes if CN VII palsy
- if suspecting CSF leak: look for halo sign, send fluid for β-2 transferrin

Treatment
- ABCs
- medical: expectant, prevent otogenic meningitis
- surgical: explore temporal bone, indications:
  - CN VII palsy (immediate and complete)
  - gunshot wound
  - depressed fracture of external auditory meatus
  - early meningitis (mastoidectomy)
  - bleeding intracranially from sinus
  - CSF otorrhea (may resolve spontaneously)

Complications
- AOM ± labyrinthitis ± mastoiditis
- meningitis/epidural abscess/brain abscess
- post-traumatic cholesteatoma

Facial Nerve (CN VII) Paralysis

Etiology
- supranuclear and nuclear (MS, poliomyelitis, cerebral tumors)
- infranuclear

Treatment
- treat according to etiology plus provide corneal protection with artificial tears, nocturnal lid taping, tarsorrhaphy, gold weighting of upper lid
- facial paralysis that does not resolve with time or with medical treatment will often be referred for possible reanimation techniques to restore function
  - common reanimation techniques include
    - direct facial nerve anastomosis
    - interpositional grafts
    - anastomosis to other motor nerves
    - muscle transpositions

Signs of Basilar Skull Fracture
- Battle’s Sign: ecchymosis of the mastoid process of the temporal bone
- Raccoon Eyes
- CSF Rhinorrhea/Otorrhea
- Cranial Nerve Involvement: facial palsy
  - CN VII, nystagmus → CN VI, facial numbness → CN V

The halo sign: the double ringed appearance of CSF fluid on white filter paper as it separates out from blood

Hemotympanum can be indicative of temporal bone trauma

Allergic Rhinitis (Hay Fever)

Definition
• rhinitis characterized by an IgE-mediated hypersensitivity to foreign allergens
• acute-and-seasonal or chronic-and-perennial
• perennial allergic rhinitis often confused with recurrent colds

Etiology
• when allergens contact the respiratory mucosa, specific IgE antibody is produced in susceptible hosts
• concentration of allergen in the ambient air correlates directly with the rhinitis symptoms

Epidemiology
• age at onset usually <20 yr
• more common in those with a personal or family history of allergies/atopy

Clinical Features
• nasal: obstruction with pruritus, sneezing
• clear rhinorrhea (containing increased eosinophils)
• itching of eyes with tearing
• frontal headache and pressure
• mucosa: swollen, pale, “boggy”
• seasonal (summer, spring, early autumn)
  ▪ pollens from trees
  ▪ lasts several weeks, disappears, and recurs following year at same time
• perennial
  ▪ inhaled: house dust, wool, feathers, foods, tobacco, hair, mold
  ▪ ingested: wheat, eggs, milk, nuts
  ▪ occurs intermittently for years with no pattern or may be constantly present

Complications
• chronic sinusitis/polyps
• serous otitis media

Diagnosis
• history
• direct exam
• allergy testing

Treatment
• education: identification and avoidance of allergen
• nasal irrigation with saline
• antihistamines (e.g. diphenhydramine, fexofenadine)
• oral decongestants (e.g. pseudoephedrine, phenylpropanolamine)
• topical decongestant (may lead to rhinitis medicamentosa)
• other topicals: steroids (fluticasone), disodium cromoglycate, antihistamines, ipratropium bromide
• oral steroids if severe
• desensitization by allergen immunotherapy
**Vasomotor Rhinitis**

- neurovascular disorder of nasal parasympathetic system (vidian nerve) affecting mucosal blood vessels
- nonspecific reflex hypersensitivity of nasal mucosa
- caused by:
  - temperature change
  - alcohol, dust, smoke
  - stress, anxiety, neurosis
  - endocrine: hypothyroidism, pregnancy, menopause
  - parasympathomimetic drugs
  - beware of rhinitis medicamentosa: reactive vasodilation due to prolonged use (>5 d) of nasal drops and sprays

**Clinical Features**

- chronic intermittent nasal obstruction, varies from side to side
- rhinorrhea: thin, watery
- mucosa and turbinates: swollen
- nasal allergy must be ruled out

**Treatment**

- elimination of irritant factors
- parasympathetic blocker (Atrovent® nasal spray)
- steroids (e.g. beclomethasone, fluticasone)
- surgery (often of limited lasting benefit): electrocautery, cryosurgery, laser treatment, or removal of inferior or middle turbinates
- vidian neurectomy (rarely done)
- symptomatic relief with exercise (increased sympathetic tone)

---

**Rhinosinusitis**

**Pathogenesis of Rhinosinusitis**

- ostial obstruction or dysfunctional cilia permit stagnant mucous and, consequently, infection
- all sinuses drain to a common prechamber under the middle meatus called the osteomeatal complex

**Definition**

- inflammation of the mucosal lining of the sinuses and nasal passages

**Classification**

- acute: <4 wk
- subacute: 4-8 wk
- chronic: >8-12 wk

**Table 13. Etiologies of Rhinosinusitis**

Acute Bacterial Rhinosinusitis

Definition
- bacterial infection of the paranasal sinuses and nasal passages lasting >7 d
- clinical diagnosis requiring ≥2 major symptoms, at least one of the symptoms is either nasal obstruction or purulent/discolored nasal discharge

- major symptoms
  - facial pain/pressure/fullness
  - nasal obstruction
  - purulent/discolored nasal discharge
  - hyposmia/anosmia

- minor symptoms
  - headache
  - halitosis
  - fatigue
  - dental pain
  - cough
  - ear pain/fullness

Etiology
- bacteria: S. pneumoniae (35%), H. influenzae (35%), M. catarrhalis, S. aureus, anaerobes (dental)
- children are more prone to a bacterial etiology, but viral is still more common
- maxillary sinus most commonly affected
- must rule out fungal causes (mucormycosis) in immunocompromised hosts (especially if painless, black or pale mucosa on examination)

Clinical Features
- sudden onset of
  - nasal blockage/congestion and/or purulent nasal discharge/posterior nasal drip
  - ± facial pain or pressure, hyposmia, sore throat
- persistent/worsening symptoms >5-7 d or presence of purulence for 3-4 d with high fever
- speculum exam: erythematous mucosa, mucopurulent discharge, pus originating from the middle meatus
- predisposing factors: viral URTI, allergy, dental disease, anatomical defects
- differentiate from acute viral rhinosinusitis (course: <10 d, peaks by 3 d)

Management
- depends on symptom severity (i.e. intensity/duration of symptoms, impact on quality of life)
  - mild-moderate: INCS
  - if no response within 72 h, add antibiotics
  - severe: INCS + antibiotics
  - antibiotics
    - 1st line: amoxicillin x 10 d (TMP-SMX or macrolide if penicillin allergy)
    - if no response to 1st line antibiotics within 72 h, switch to 2nd line
      - 2nd line: fluoroquinolones or amoxicillin-clavulanic acid inhibitors
    - adjuvant therapy (saline irrigation, analgesics, oral/topical decongestant) may provide symptomatic relief
  - CT indicated only if complications are suspected

Chronic Rhinosinusitis

Definition
- inflammation of the mucosa of paranasal sinuses and nasal passages >8-12 wk
- diagnosis requiring ≥2 major symptoms for >8-12 wk and ≥1 objective finding of inflammation of the paranasal sinuses (CT/endoscopy)

Etiology
- unclear etiology but the following may contribute or predispose:
  - inadequate treatment of acute rhinosinusitis
  - bacterial colonization/biofilms
    - S. aureus, enterobacteriaceae, Pseudomonas, S. pneumoniae, H. influenzae, β-hemolytic streptococci
  - fungal infection (e.g. Aspergillus, Zygomycetes, Candida)
  - anatomic abnormality (e.g. lost ostia patency, deviated septum – predisposing factors)
  - allergy/allergic rhinitis
  - ciliary disorder (e.g. cystic fibrosis, Kartagener syndrome)
  - chronic inflammatory disorder (e.g. GPA)
  - untreated dental disease

Acute Rhinosinusitis Complications
Consider hospitalization if any of the following are suspected
- Orbital (Chandler’s classification)
  - Orbital cellulitis
  - Subperiosteal abscess
  - Orbital abscess
  - Cavernous sinus thrombosis
- Intracranial
  - Meningitis
  - Abscess
  - Bony
    - Subperiosteal frontal bone abscess (“Pott’s Puffy tumor”)
  - Osteomyelitis
- Neurologic
  - Superior orbital fissure syndrome (CN III/IV/VI palsy, immobile globe, dilated pupils, ptosis, V1 hypesthesia)
  - Orbital apex syndrome (as above, plus neuritis, papilledema, decreased visual acuity)

FESS = Functional Endoscopic Sinus Surgery
Opening of the entire osteomeatal complex in order to facilitate drainage while sparing the sinus mucosa

Allergic fungal rhinosinusitis is a chronic sinusitis affecting mostly young, immunocompetent, atopic individuals.
Treatment options include FESS ± intranasal topical steroids, antifungals, and immunotherapy
Clinical Features (similar to acute, but less severe)
- chronic nasal obstruction
- purulent anterior/posterior nasal discharge
- facial congestion/fullness
- facial pain/pressure
- hyposmia/anosmia
- halitosis
- chronic cough
- maxillary dental pain

Management
- identify and address contributing or predisposing factors
- obtain CT or perform endoscopy
- if polyps present: INCS, oral steroids ± antibiotics (if signs of infection), refer to otolaryngologist/H&N surgeon
- if polyps absent: INCS, antibiotics, saline irrigation, oral steroids (severe cases)
- antibiotics for 3-6 wk
  - amoxillin-clavulanic acid inhibitors, fluoroquinolone (moxifloxacin), macrolide (clarithromycin), clindamycin, Flagyl® (metronidazole)
- surgery if medical therapy fails or fungal sinusitis: FESS, balloon sinoplasty

Complications
- same as acute sinusitis, mucocele

Epistaxis

Blood Supply to the Nasal Septum (see Figure 4, OT3)
1. Superior posterior septum
   - internal carotid → ophthalmic → anterior/posterior ethmoidal
2. Posterior septum
   - external carotid → internal maxillary → sphenopalatine artery → nasopalatine
3. Lower anterior septum
   - external carotid → facial artery → superior labial artery → nasal branch
   - external carotid → internal maxillary → descending palatine → greater palatine
- these arteries all anastomose to form Kiesselbach’s plexus, located at Little’s area (anterior-inferior portion of the cartilaginous septum)
- bleeding from above middle turbinate is internal carotid, and from below is external carotid

Table 14. Etiology of Epistaxis

</table>

Investigations
- CBC, PT/PTT (if indicated)
- x-ray, CT as needed

Treatment
- locate bleeding and achieve hemostasis
1. ABCs
- lean patient forward to minimize swallowing blood and avoid airway obstruction
- apply constant firm pressure for 20 min on cartilaginous part of nose (not bony pyramid)
- if significant bleeding, assess vitals for signs of hemorrhagic shock ± IV NS, cross-match blood

2. Determine Site of Bleeding
- anterior/posterior hemorrhage defined by location in relationship to bony septum
- visualize nasal cavity with speculum
- use cotton pledget with topical lidocaine ± topical decongestant to help identify area of bleeding (often anterior septum)
- if suspicious bleeding disorder, coagulation workup (platelet number and platelet function assay)

3. Control the Bleeding
- first line topical vasoconstrictors
- if first line fails and bleeding adequately visualized, cauterize with silver nitrate
- do not cauterize both sides of the septum at one time due to risk of septal perforation from loss of septal blood supply
  A. Anterior hemorrhage treatment
   - if fail to achieve hemostasis with cauterization:
     • place anterior pack* with half inch Vaseline®-soaked ribbon gauze strips layered from nasal floor toward nasal roof extending to posterior choanae or lubricated absorbable packing (i.e. Gelfoam wrapped in Surgicel®) for 2-3 d
     • can also attempt packing with Merocel® or nasal tampons of different shapes
     • can also apply Floseal® (hemostatic matrix consisting of topical human thrombin and cross-linked gelatin) if other methods fail
  B. Posterior hemorrhage treatment
   - if unable to visualize bleeding source, then usually posterior source:
     • place posterior pack* using a Foley catheter, gauze pack, or Epistat® balloon
     • subsequently, layer anterior packing bilaterally
     • admit to hospital with packs in for 3-5 d
     • watch for complications: hypoxemia (naso-pulmonic reflex), toxic shock syndrome (Rx: remove packs immediately), pharyngeal fibrosis/stenosis, alar/septal necrosis, aspiration
  C. If anterior/posterior packs fail to control epistaxis
   - ligation or embolization of culprit arterial supply by interventional radiology
   - ± septoplasty
   * antibiotics for any posterior pack or any pack left for >48 h because of risk of toxic shock syndrome

4. Prevention
- prevent drying of nasal mucosa with humidifiers, saline spray, or topical ointments
- avoidance of irritants
- medical management of HTN and coagulopathies

---

**Hoarseness**

**Definitions**
- hoarseness: change in voice quality, ranging from voice harshness to voice weakness; reflects abnormalities anywhere along the vocal tract from oral cavity to lungs
- dysphonia: a general alteration in voice quality
- aphonia: no sound emanates from vocal folds

**Acute Laryngitis**

**Definition**
- <2 wk inflammatory changes in laryngeal mucosa

**Etiology**
- viral: influenza, adenovirus
- bacterial: Group A Streptococcus
- mechanical acute voice strain → submucosal hemorrhage → vocal cord edema → hoarseness
- environmental: toxic fume inhalation

**Clinical Features**
- URTI symptoms, hoarseness, aphonia, cough attacks, ± dyspnea
- true vocal cords erythematous/edematous with vascular injection and normal mobility

**Treatment**
- usually self-limited, resolves within ~1 wk
- voice rest
- humidification
- hydration

**Vocal Cord Paralysis**

**Unilateral:** affected cord lies in the parmedian position, inadequate glottic closure during phonation → weak, breathy voice. Usually medializes with time whereby phonation and aspiration improve. Treatment options include voice therapy, injection laryngoplasty (Radiesse), medialization using silastic block

**Bilateral:** cords rest in midline therefore voice remains good but respiratory function is compromised and may present as stridor. If no respiratory issues, may monitor closely and wait for improvement. If respiratory issues, intubate and will likely require a tracheotomy

---

If hoarseness present for >2 wk in a smoker, laryngoscopy must be done to rule out malignancy
• avoid irritants (e.g. smoking)
• treat with antibiotics if there is evidence of coexistent bacterial pharyngitis

### Chronic Laryngitis

**Definition**
- >2 wk inflammatory changes in laryngeal mucosa

**Etiology**
- repeated attacks of acute laryngitis
- chronic irritants (dust, smoke, chemical fumes)
- chronic voice strain
- chronic rhinosinusitis with postnasal drip
- chronic EtOH use
- esophageal disorders: GERD, Zenker's diverticulum, hiatus hernia
- systemic: allergy, hypothyroidism, Addison's disease

**Clinical Features**
- chronic dysphonia: rule out malignancy
- cough, globus sensation, frequent throat clearing 2º to GERD
- laryngoscopy: cords erythematous, thickened with ulceration/granuloma formation, and normal mobility

**Treatment**
- remove offending irritants
- treat related disorders (e.g. antisecretory therapy for GERD)
- speech therapy with voice rest
- ± antibiotics ± steroids to decrease inflammation
- laryngoscopy to rule out malignancy

### Vocal Cord Polyps

**Definition**
- structural manifestation of vocal cord irritation
- acutely, polyp forms 2º to capillary damage in the subepithelial space during extreme voice exertion

**Etiology**
- most common benign tumor of vocal cords
- voice strain (muscle tension dysphonia)
- laryngeal irritants (GERD, allergies, tobacco)

**Epidemiology**
- 30-50 yr of age
- M>F

**Clinical Features**
- hoarseness, aphony, cough attacks ± dyspnea
- pedicled or sessile polyp on free edge of vocal cord
- typically polyp asymmetrical, soft, and smooth
- more common on the anterior 1/3 of the vocal cord
- intermittent respiratory distress with large polyps

**Treatment**
- avoid irritants
- endoscopic laryngeal microsurgical removal if persistent or if high risk of malignancy

### Vocal Cord Nodules

**Definition**
- vocal cord callus
- i.e. “screamer’s or singer’s nodules”

**Etiology**
- early nodules occur 2º to submucosal hemorrhage
- mature nodules result from hyalinization which occurs with long-term voice abuse
- chronic voice strain
- frequent URTI, smoke, EtOH
Epidemiology
- frequently in singers, children, bartenders, and school teachers
- F>M

Clinical Features
- hoarseness worst at end of day
- on laryngoscopy
  - often bilateral
  - at the junction of the anterior 1/3 and posterior 2/3 of the vocal cords – point of maximal cord vibration
- chronic nodules may become fibrotic, hard, and white

Treatment
- voice rest
- hydration
- speech therapy
- avoid irritants
- surgery rarely indicated for refractory nodules

Benign Laryngeal Papillomas

Etiology
- HPV types 6, 11
- possible hormonal influence, possibly acquired during delivery

Epidemiology
- biphasic distribution: 1) birth to puberty (most common laryngeal tumor) and 2) adulthood

Clinical Features
- hoarseness and airway obstruction
- can seed into tracheobronchial tree
- highly resistant to complete removal
- some juvenile papillomas resolve spontaneously at puberty
- may undergo malignant transformation
- laryngoscopy shows wart-like lesions in supraglottic larynx and trachea

Treatment
- microdebridement or CO₂ laser
- adjuvants under investigation: interferon, cidofovir, acyclovir
- HPV vaccine may prevent/decrease the incidence but more research is needed

Laryngeal Carcinoma
- see Neoplasms of the Head and Neck, OT35

Salivary Glands

Sialadenitis

Definition
- inflammation of salivary glands

Etiology
- viral most common (mumps)
- bacterial causes: S. aureus, S. pneumoniae, H. influenzae
- obstructive vs. non-obstructive
- obstructive infection involves salivary stasis and bacterial retrograde flow

Predisposing Factors
- HIV
- anorexia/bulimia
- Sjögren's syndrome
- Cushing's, hypothyroidism, DM
- hepatic/renal failure
- meds that increase stasis: diuretics, TCAs, β-blockers, anticholinergics, antibiotics
- sialolithiasis (can cause chronic sialadenitis)
Clinical Features
- acute onset of pain and edema of parotid or submandibular gland that may lead to marked swelling
- ± fever
- ± leukocytosis
- ± suppurative drainage from punctum of the gland

Investigations
- U/S imaging to differentiate obstructive vs. non-obstructive sialadenitis

Treatment
- bacterial: treat with cloxacillin ± abscess drainage, sialogogues
- viral: no treatment

Sialolithiasis

Definition
- ductal stone (mainly hydroxyapatite) in adults, sand/sludge in children, leading to chronic sialadenitis
- 80% in submandibular gland, <20% in parotid gland, ~1% in sublingual gland

Risk Factors
- any condition causing duct stenosis or a change in salivary secretions (e.g. dehydration, DM, EtOH, hypercalcemia, psychiatric medication)

Clinical Features
- pain and tenderness over involved gland
- intermittent swelling related to meals
- digital palpation reveals presence of calculus

Investigations
- U/S ± sialogram

Treatment
- may resolve spontaneously
- encourage salivation to clear calculus
- massage, analgesia, antibiotics, sialogogues (e.g. lemon wedges, sour lemon candies), warm compresses
- remove calculi endoscopically, by dilating duct or orifice, or by excision through floor of the mouth
- if calculus is within the gland parenchyma, the whole gland must be excised

Salivary Gland Neoplasms

Etiology
- anatomic distribution
  - parotid gland: 70-85%
  - submandibular gland: 8-15%
  - sublingual gland: 1%
  - minor salivary glands, most concentrated in hard palate: 5-8%
- malignant (see Table 15, OT32 and Table 16, OT36)
- benign
  - benign mixed (pleomorphic adenoma): 80%
  - Warthin's tumor (3-10% bilateral, M>F): 10%
  - cysts, lymph nodes and adenomas: 10%
  - oncocytoma: <1%

Epidemiology
- 3-6% of all head and neck neoplasms in adults
- mean age at presentation: 55-65
  - M=F
Parotid Gland Neoplasms

Clinical Features
- 80% benign (pleomorphic adenoma: most common), 20% malignant (mucoepidermoid: most common)
- if bilateral, suggests benign process (Warthin’s tumor, Sjögren’s, bulimia, mumps) or possible lymphoma
- facial nerve involvement (i.e. facial paralysis): increases risk of malignancy

Investigations
- FNA biopsy
- CT, U/S, or MRI to determine extent of tumor

Treatment
- treatment of choice is surgery for all salivary gland neoplasms – benign and malignant
- pleomorphic adenomas are excised due to risk of malignant transformation (5% risk over prolonged period of time)
- superficial tumor
  - superficial parotidectomy above plane of CN VII ± radiation
  - incisional biopsy contraindicated
- deep lesion
  - near-total parotidectomy sparing as much of CN VII as possible
  - if CN VII involved then it is removed and cable grafted
- complications of parotid surgery
  - hematoma, infection, salivary fistula, temporary facial paresis, Frey’s syndrome (gustatory sweating)

Frey’s syndrome is a post-operative complication characterized by gustatory sweating. It is due to aberrant innervation of cutaneous sweat glands by parasympathetic nerve fibers that are divided during surgery.

Prognosis
- benign: excellent, <5% of pleomorphic adenomas may recur
- malignant: dependent on stage and type of malignancy (see Table 16, OT36)

Neck Masses

Approach to a Neck Mass
- ensure that the neck mass is not a normal neck structure (hyoid, transverse process of C1 vertebra, prominent carotid bulb)
- any neck mass persisting for >2 wk should be investigated for possible neoplastic causes

Table 15. Acquired Causes of Neck Lumps According to Age

<table>
<thead>
<tr>
<th>Age (yr)</th>
<th>Possible Causes of Neck Lump</th>
</tr>
</thead>
<tbody>

<tr>
<td>&gt;40</td>
<td>1. Neoplastic 2. Inflammatory 3. Congenital</td>
</tr>
</tbody>
</table>

Differential Diagnosis
- congenital
  - lateral (branchial cleft cyst, lymphatic/venous/venolymphatic malformation)
  - midline (thyroglossal duct cyst, dermoid cyst, laryngocele)
- infectious/inflammatory
  - reactive lymphadenopathy (2º to tonsillitis, pharyngitis)
  - infectious mononucleosis
  - Kawasaki, Kikuchi, Kimura
  - HIV
  - salivary gland calculi, sialadenitis
  - thyroiditis
- granulomatous disease
  - mycobacterial infections
  - sarcoidosis
- neoplastic
  - lymphoma
  - salivary gland tumors
  - thyroid tumors
  - metastatic malignancy ("unknown primary")

Evaluation

Investigations
- history and physical (including nasopharynx and larynx)
- all other investigations and imaging are dependent upon clinical suspicion following history and physical
- laboratory investigations
  - WBC: infection vs. lymphoma
  - Mantoux TB test
  - thyroid function tests and scan
- imaging
  - neck U/S
  - CT scan
  - angiography: vascularity and blood supply to mass
- biopsy: for histologic examination
  - FNA: least invasive
  - needle biopsy
  - open biopsy: for lymphoma
- identification of possible primary tumor (rule out a metastatic lymph node from an "unknown primary")
  - panendoscopy: nasopharyngoscopy, laryngoscopy, esophagoscopy, bronchoscopy with washings, and biopsy of suspicious lesions
  - biopsy of normal tissue of nasopharynx, tonsils, base of tongue, and hypopharynx
  - primary identified 95% of time → stage and treat
  - primary occult 5% of time: excisional biopsy of node for histologic diagnosis → manage with radiotherapy and/or neck dissection (squamous cell carcinoma)

Congenital Neck Masses

Branchial Cleft Cysts/Fistula

Embryology
- at the 6th wk of development, the 2nd branchial arch grows over the 3rd and 4th arches and fuses with the neighbouring caudal pre-cardial swelling forming the cervical sinus
- 3 types of malformations
  1. branchial fistula: persistent communication between skin and GI tract
  2. branchial sinus: blind-ended tract opening to skin
  3. branchial cyst: persistent cervical sinus with no external opening

Clinical Features
- 2nd branchial cleft malformations most common
  - sinuses and fistulae present in infancy as a small opening anterior to the sternocleidomastoid muscle
  - cysts present as a smooth, painless, slowly enlarging lateral neck mass, often following a URTI
- 1st branchial cleft malformations present as sinus/fistula or cyst in preauricular area or on face over angle of mandible
- 3rd branchial cleft malformations present as recurrent thyroiditis or thyroid abscess and have a tract leading usually to the left pyriform sinus
- there is controversy whether or not 4th branchial cleft anomalies exist, as they may be remnants of the thyrothymic axis

Treatment
- surgical removal of cyst or fistula tract
- if infected: allow infection to settle before removal (antibiotics may be required)
Thyroglossal Duct Cysts

Embryology
- thyroid originates as ventral midline diverticulum at base of tongue caudal to junction of 3rd and 4th branchial arches (foramen cecum) and migrates down to inferior aspect of neck
- thyroglossal duct cysts are vestigial remnants of tract

Clinical Features
- usually presents in childhood or during 20-40s as a midline cyst that enlarges with URTI and elevates with swallowing and tongue protrusion

Treatment
- pre-operative antibiotics to reduce inflammation (infection before surgery is a well described cause of recurrence)
- small potential for neoplastic transformation so complete excision of cyst and tissue around tract up to foramen cecum at base of tongue with removal of central portion of hyoid bone (Sistrunk procedure) recommended
Lymphatic Malformation

Definition
- lymphatic malformation arising from vestigial lymph channels of neck

Clinical Features
- usually present by age 2
- can be macrocystic (composed of large thin-walled cysts, usually below level of mylohyoid muscle) or microcystic (composed of minute cysts, usually above level of mylohyoid muscle)
- usually painless, soft, compressible
- infection causes a sudden increase in size

Treatment
- can regress spontaneously after bacterial infection, therefore do not plan surgical intervention until several months after infection
- macrocystic lesions can be treated by sclerotherapy or surgical excision
- microcystic lesions are difficult to treat, but can be debulked

Neoplasms of the Head and Neck

Pre-Malignant Disease
- leukoplakia
  - hyperkeratosis of oral mucosa
  - risk of malignant transformation 5-20%
- erythroplakia
  - red superficial patches adjacent to normal mucosa
  - commonly associated with epithelial dysplasia
  - associated with carcinoma in situ or invasive tumor in 40% of cases
- dysplasia
  - histopathologic presence of mitoses and prominent nucleoli
  - involvement of entire mucosal thickness = carcinoma in situ
  - associated progression to invasive cancer in 15-30% of cases

Investigations
- initial metastatic screen includes CXR
- scans of liver, brain, and bone only if clinically indicated
- CT scan is superior to MRI for the detection of pathologic nodal disease and bone cortex invasion
- MRI is superior to discriminate tumor from mucus and to detect bone marrow invasion
- ± PET scans

Treatment
- treatment depends on
  - histologic grade of tumor
  - stage
  - physical and psychological health of patient
  - facilities available
  - expertise and experience of the medical and surgical oncology team
- in general
  - 1° surgery for malignant oral cavity tumors with radiotherapy reserved for salvage or poor prognostic indicators
  - 1° radiotherapy for nasopharynx, oropharynx, hypopharynx, larynx malignancies with surgery reserved for salvage
  - palliative chemotherapy for metastatic or incurable disease
  - concomitant chemotherapy increases survival in advanced disease
  - chemotherapy has a role as induction therapy prior to surgery and radiation
  - panendoscopy to detect primary disease when lymph node metastasis is identified
  - anti-EGFR treatment (cetuximab, panitumumab) has a role as concurrent therapy with radiation for SCC of the head and neck (for advanced local and regional disease)

Prognosis
- synchronous tumors occur in 9-15% of patients
- late development of 2nd primary most common cause of post-treatment failure after 36 mo

* B symptoms = fever, night sweats, chills, weight loss >10% in 6 mo  
** CHOP = cyclophosphamide, adriamycin, vincristine, prednisone

## Approach to Thyroid Nodule
- all patients with thyroid nodules require evaluation of serum TSH and ultrasound
- any nodule >5 mm with suspicious sonographic features (particularly microcalcifications) should undergo FNA
- any nodule >1 cm should undergo FNA
- when performing repeat FNA on initially non-diagnostic nodules, U/S-guided FNA should be employed
- nuclear scanning has minimal value in the investigation of the thyroid nodule

* U/S findings: cystic: risk of malignancy <1%; solid: risk of malignancy ~10%; solid with cystic components: risk of malignancy same as if solid

Pediatric Otolaryngology

Acute Otitis Media

Definition
- All of: presence of middle ear effusion (MEE); presence of middle ear inflammation (MEI); acute onset of symptoms of MEE and MEI

Epidemiology
- Most frequent diagnosis in sick children visiting clinicians’ offices and most common reason for antibiotic administration
- Peak incidence between 6-15 mo; ~85% of children have >1 episode by 3 yr old
- Seasonal variability: peaks in winter

Etiology
- Primary defect causing AOM: Eustachian tube dysfunction/obstruction → stasis/colonization by pathogens
- Bacterial: S. pneumoniae, non-typable H. influenzae, M. catarrhalis, Group A Streptococcus, S. aureus
- Viral: RSV, influenza, parainfluenza, adenovirus
- Commonly due to bacterial/viral co-infection

Predisposing Factors
- Eustachian tube dysfunction/obstruction
  - Swelling of tubal mucosa
  - Upper respiratory tract infection (URTI)
  - Allergic rhinitis
  - Chronic rhinosinusitis
  - Obstruction/infiltration of Eustachian tube ostium
  - Tumor: nasopharyngeal carcinoma (adults)
  - Adenoid hypertrophy (not due to obstruction but maintaining a source of infection)
  - Barotrauma (sudden changes in air pressure)
  - Inadequate tensor palatini function: cleft palate (even after repair)
  - Abnormal Eustachian tube
    - Down syndrome (horizontal position of Eustachian tube), Crouzon syndrome, cleft palate, and Apert syndrome
  - Disruption of action of cilia of Eustachian tube: Kartagener’s syndrome
  - Mucus secreting cells
  - Capillary network that provides humoral factors, PMNs, phagocytic cells
- Immunosuppression/deficiency due to chemotherapy, steroids, DM, hypogammaglobulinemia, cystic fibrosis

Risk Factors
- Non-modifiable: young age, family history of OM, prematurity, orofacial abnormalities, immunodeficiencies, Down syndrome, race, and ethnicity
- Modifiable: lack of breastfeeding, day care attendance, household crowding, exposure to cigarette smoke and air pollution, pacifier use

Pathogenesis
- Obstruction of Eustachian tube → air absorbed in middle ear → negative pressure (an irritant to middle ear mucosa) → Edema of mucosa with exudate/effusion → infection of exudate from nasopharyngeal secretions

Clinical Features
- Triad of otalgia, fever (especially in younger children), and conductive hearing loss
- Rarely tinnitus, vertigo, and/or facial nerve paralysis
- Otorrhea if tympanic membrane perforated
- Infants/toddlers
  - Ear-tugging (this alone is not a good indicator of pathology)
  - Hearing loss, balance disturbances (rare)
  - Irritable, poor sleeping
  - Vomiting and diarrhea
  - Anorexia
- Otoscopy of TM
- Hyperemia
- Bulging, pus may be seen behind TM
- Loss of landmarks: handle and long process of malleus not visible

Acute Otitis Media in Children

Clinical Assessment of AOM in Pediatrics
JAMA 2010;304:2161-2169

In assessment of AOM in pediatrics, ear pain is the most useful symptom with a likelihood ratio (LR) between 3.0-7.3. Useful otoscopic signs include erythematous (LR 8.4, 95% CI 7-11), cloudy (LR 34, 95% CI 28-42), bulging (LR 51, 95% CI 36-73), and immobile tympanic membrane (LR 21, 95% CI 16-27) or pneumatic otoscopy.

Main Outcomes: 1) Pain at 24 h, 2-3 d, and 4-7 d; 2) Abnormal tympanometry findings; 3) TM perforation; 4) Contralateral otitis; 5) AOM recurrences; 6) Serious complications from AOM; 7) Adverse effects from antibiotics.

Results: treatment with antibiotics had no significant impact on pain at 24 h. However, pain at 2-3 d and 4-7 d was lower in the antibiotic groups with a NNT of 20. Antibiotics had no significant effect on tympanometry findings, number of AOM recurrences, or severity of complications. Antibiotic treatment led to a significant reduction in TM perforation (NNT 33) and halved contralateral AOM (NNT 11). Adverse events (vomiting, diarrhea, or rash) occurred more often in children taking antibiotics.

Conclusions: The role of antibiotics is largely restricted to pain control at 2-7 d, but most (92%) settle without antibiotics. This can also be achieved by analgesics. However, antibiotic treatment can reduce risk of TM perforation and contralateral AOM episodes. These benefits must be weighed against risks of adverse events from antibiotics.

Antibiotics for Acute Otitis Media in Children
Cochrane LB Syst Rev 2013;1(000):0019

Study: Meta-analysis of Randomized Controlled Trials (RCTs) on children (1-15 mo) with acute otitis media comparing any antibiotic regime to placebo and expectant observation.

Main Outcomes: 1) Pain at 2-3 d; 2) Abnormal tympanometry findings; 3) TM perforation; 4) Contralateral otitis; 5) AOM recurrences; 6) Serious complications from AOM; 7) Adverse effects from antibiotics.

Results: Treatment with antibiotics had no significant impact on pain at 24 h. However, pain at 2-3 d and 4-7 d was lower in the antibiotic groups with a NNT of 20. Antibiotics had no significant effect on tympanometry findings, number of AOM recurrences, or severity of complications. Antibiotic treatment led to a significant reduction in TM perforations (NNT 33) and halved contralateral AOM (NNT 11). Adverse events (vomiting, diarrhea, or rash) occurred more often in children taking antibiotics.

Conclusions: The role of antibiotics is largely restricted to pain control at 2-7 d, but most (92%) settle without antibiotics. This can also be achieved by analgesics. However, antibiotic treatment can reduce risk of TM perforation and contralateral AOM episodes. These benefits must be weighed against risks of adverse events from antibiotics.

Indications for Myringotomy and Tympanostomy Tubes in Recurrent AOM (RAOM) and OME

- Chronic bilateral OME and documented hearing difficulties >3 mo
- Unilateral bilateral OME >3 mo and symptoms likely attributable to OME (e.g. balance problems, poor school performance, ear discomfort, etc.)
- At-risk children (permanent hearing loss, speech/language delay, autism-spectrum disorder, syndromes/trafalocal disturbances, blindness, cleft palate, developmental delays) with unilateral or bilateral OME with type B tympanogram or persistent effusion >3 mo
- RAOM (>3 episodes in 6 mo or >4 in 12 mo) with unilateral or bilateral middle ear effusion

Diagnosis
- **history**
  - acute onset of otalgia or ear tugging in a preverbal child, otorrhea, decreased hearing
  - unexplained irritability, fever, upper respiratory symptoms, poor sleeping, anorexia, N/V, and diarrhea
- **physical**
  - febrile
  - MEE on otoscopy: immobile tympanic membrane, acute otorrhea, loss of bony landmarks, opacification of TM, air-fluid level behind TM
  - MEI on otoscopy: bulging TM with marked discoloration (hemorrhagic, red, gray, or yellow)

Management
- **observation** for 48-72 h without antimicrobials may be appropriate since >80% of AOM in children resolve spontaneously
- **criteria for watchful waiting approach**
  - child is >6 mo old
  - child does not have immunodeficiency, chronic cardiac or pulmonary disease, anatomical abnormalities of the head or neck, a history of complicated otitis media (suppurative complications of chronic perforation) or Down syndrome
  - the illness is not severe: otalgia appears to be mild and fever is <102.2°F in the absence of antipyretics
  - parents are capable of recognizing signs of worsening illness and can readily access medical care if the child does not improve
- antimicrobials are indicated if child does not meet the criteria for watchful waiting or does not improve/worsens during observation
- maintain hydration
- symptomatic relief: acetaminophen, ibuprofen
- referral to otolaryngology for myringotomy and tympanostomy tubes may be warranted for recurrent infections

Treatment
- **antimicrobial agents for AOM**
  - 1st line treatment (no penicillin allergy)
    - amoxicillin: 75 mg/kg/d to 90 mg/kg/d divided 3x/d
  - 2nd line treatment
    - cefprozil: 30 mg/kg/d divided 2x/d
    - cefuroxime axetil: 30 mg/kg/d divided 2x/d
    - ceftriaxone: 50 mg/kg intramuscularly (or intravenously) x 1 dose
    - azithromycin: 10 mg/kg OD x 1 dose, then 5 mg/kg OD x 4 doses
    - clarithromycin: 15 mg/kg/d divided 2x/d
  - if initial therapy fails (i.e. no symptomatic improvement after 2-3 d)
    - amoxicillin-clavulanate: 90 mg/kg/d amoxicillin, 6.4 mg/kg/d clavulanate divided 2x/d for 10 d.
  - if AOM-related symptoms do not resolve with amoxicillin/clavulanate, a course of ceftriaxone 50 mg/kg/d intramuscularly (or intravenously) 1/d x 3 doses could be considered

Complications
- extracranial
  - hearing loss and speech delay (secondary to persistent MEE), TM perforation, extension of suppurative process to adjacent structures (mastoiditis, petrositis, labyrinthitis), cholesteatoma, facial nerve palsy, middle ear atelectasis, ossicular necrosis, vestibular dysfunction, persistent effusion (often leading to hearing loss)
- intracranial
  - meningitis, epidural and brain abscess, subdural empyema, lateral and cavernous sinus thrombosis, carotid artery thrombosis, facial nerve paralysis
- other
  - mastoiditis, labyrinthitis, sigmoid sinus thrombophlebitis

**Otitis Media with Effusion**

Definition
- presence of fluid in the middle ear without signs or symptoms of ear infection

Epidemiology
- most common cause of pediatric hearing loss
- not exclusively a pediatric disease
- follows AOM frequently in children
- middle ear effusions have been shown to persist following an episode of AOM for 1 mo in 40% of children, 2 mo in 20%, and >3 mo in 10%
Risk Factors
- same as AOM

Clinical Features
- conductive hearing loss ± tinnitus
  - confirm with audiogram and tympanogram (flat) (see Figure 16B, OT10 and Figure 17B, OT11)
- fullness – blocked ear
- ± pain, low grade fever
- otoscopy of tympanic membrane:
  - discoloration – amber or dull gray with "glue" ear
  - meniscus fluid level behind TM
  - air bubbles
  - retraction pockets/TM atelectasis
- most reliable finding with pneumotoscopy is immobility

Treatment
- expectant: 90% resolve by 3 mo
- document hearing loss with audiogram
- no clinical evidence that antihistamines, decongestants, or antibiotics clear disease faster
- surgery: myringotomy ± ventilation tubes ± adenoidectomy (if enlarged or on insertion of second set of tubes after first set falls out)
- ventilation tubes to equalize pressure and drain ear

Complications of Otitis Media with Effusion
- hearing loss, speech delay, learning problems in young children
- chronic mastoiditis
- ossicular erosion
- cholesteatoma especially when retraction pockets involve pars flaccida
- retraction of tympanic membrane, atelectasis, ossicular fixation

Adenoid Hypertrophy
- size peaks at age 5 and resolves by age 12
- increase in size with repeated URTI and allergies

Clinical Features
- nasal obstruction
  - adenoid facies (open mouth, high arched palate, narrow midface, malocclusion)
  - history of hypernasal voice and snoring
  - long-term mouth breather; minimal air escape through nose
- choanal obstruction
  - chronic rhinosinusitis/rhinitis
  - obstructive sleep apnea
  - chronic inflammation
  - nasal discharge, post-nasal drip, and cough
  - cervical lymphadenopathy

Diagnosis
- enlarged adenoids on nasopharyngeal exam (usually with flexible nasopharyngoscope)
- enlarged adenoid shadow on lateral soft tissue x-ray

Complications
- Eustachian tube obstruction leading to serous otitis media
- interference with nasal breathing, necessitating mouth-breathing
- malocclusion
- sleep apnea/respiratory disturbance
- orofacial developmental abnormalities

Adenoidectomy

Indications for Adenoidectomy
- chronic upper airway obstruction with sleep disturbance/apnea ± cor pulmonale
- chronic nasopharyngitis resistant to medical treatment
- chronic serous otitis media and chronic suppurative otitis media (with 2nd set of tubes)
- recurrent acute otitis media resistant to antibiotics
- suspicion of nasopharyngeal malignancy
- persistent rhinorrhea secondary to nasal obstruction
Contraindications
- uncontrollable coagulopathy
- recent pharyngeal infection
- conditions that predispose to velopharyngeal insufficiency (cleft palate, impaired palatal function, or enlarged pharynx)

Complications
- bleeding, infection
- velopharyngeal insufficiency (hypernasal voice or nasal regurgitation)
- scarring of Eustachian tube orifice

Sleep-Disordered Breathing in Children

Definition
- spectrum of sleep-related breathing abnormalities ranging from snoring to OSA

Epidemiology
- peak incidence between 2-8 yr when tonsils and adenoids are the largest relative to the pharyngeal airway

Etiology
- due to a combination of anatomic and neuromuscular factors
  - adenotonsillar hypertrophy
  - craniofacial abnormalities
  - neuromuscular hypotonia (i.e. cerebral palsy, Down syndrome)
  - obesity

Clinical Features
- heavy snoring, mouth breathing, pauses or apnea, enuresis, excessive daytime sleepiness, behavioral/learning problems, diagnosis of ADHD, morning headache, failure to thrive

Investigations
- flexible nasopharyngoscopy for assessment of nasopharynx and adenoids
- polysomnography (apnea-hypopnea index >1/h considered abnormal)

Treatment
- surgical: bilateral tonsillectomy and adenoidectomy
- nonsurgical: CPAP, BiPAP, sleep hygiene

Acute Tonsillitis

see Pediatrics, P59

Peritonsillar Abscess (Quinsy)

Definition
- cellulitis of space behind tonsillar capsule extending onto soft palate leading to abscess

Etiology
- bacterial: Group A strep (GAS) (50% of cases), S. pyogenes, S. aureus, H. influenzae, and anaerobes

Epidemiology
- can develop from acute tonsillitis with infection spreading into plane of tonsillar bed
- unilateral
- most common in 15-30 yr age group

Clinical Features
- fever and dehydration
- sore throat, dysphagia, and odynophagia
- extensive peritonsillar swelling but tonsil may appear normal
- edema of soft palate
- uvular deviation
- trismus (due to irritation and reflex spasm of the medial pterygoid)
- dysphonia (edema → failure to elevate palate) 2º to CN X involvement
- unilateral referred otalgia
- cervical lymphadenitis
Complications
- aspiration pneumonia 2º to spontaneous rupture of abscess
- airway obstruction
- lateral dissection into parapharyngeal and/or carotid space
- bacteremia
- retropharyngeal abscess

Treatment
- secure airway
- surgical drainage (incision or needle aspiration) with C&S
- warm saline irrigation
- IV penicillin G x 10 d if cultures positive for GAS
- add PO/IV metronidazole or clindamycin x 10 d if culture positive for Bacteroides
- consider tonsillectomy after second episode

Other Sources of Parapharyngeal Space Infections
- pharyngitis
- acute suppurative parotitis (see Salivary Glands, OT30)
- AOM
- mastoiditis (Bezold’s abscess)
- odontogenic infection

Tonsillectomy

Absolute Indications
- most common indication: sleep-disordered breathing
- 2nd most common indication: recurrent throat infections
- tonsillar hypertrophy causing upper airway obstruction, obstructive sleep apnea, severe dysphagia, or cardiopulmonary complications such as cor pulmonale
- suspicion of malignancy (e.g. lymphoma, squamous cell carcinoma)
- orofacial/dental deformity
- hemorrhagic tonsillitis

Relative Indications (To Reduce Disease Burden)
- recurrent throat infection with a frequency of at least 7 episodes in the past year, at least 5 episodes per year for 2 yr, or at least 3 episodes per year for 3 yr, with documentation in the medical record for each episode of sore throat and 1 or more of the following: temperature >38.3°C, cervical adenopathy, tonsillar exudate, or positive test for Group A β-hemolytic streptococcus (Paradise Criteria)
- chronic tonsillitis with halitosis (bad breath) or sore throat ± tonsilloliths (clusters of calcified material that form in the crevices of the tonsils)
- complications of tonsillitis: quinsy/peritonsillar abscess, parapharyngeal abscess, retropharyngeal abscess
- failure to thrive

Relative Contraindications
- velopharyngeal insufficiency: overt or submucous/covert cleft of palate, impaired palatal function due to neurological or neuro-muscular abnormalities
- hematologic: coagulopathy, anemia
- infectious: active local infection without urgent obstructive symptoms

Complications
- hemorrhage: early – within 24 h; delayed – 7-10 d
- odynophagia and/or otalgia; dehydration 2º to odynophagia
- infection
- atlantoaxial subluxation (Grisel’s syndrome): rare

Airway Problems in Children

DIFFERENTIAL DIAGNOSIS BY AGE GROUP

Neonates (Obligate Nose Breathers)
- extralaryngeal
  - choanal atresia (e.g. CHARGE syndrome)
  - nasopharyngeal dermoid, glioma, encephalocele
  - glossoptosis: Pierre-Robin sequence, Down syndrome, lymphatic malformation, hemangioma
- laryngeal
  - laryngomalacia: most common cause of stridor in children
  - laryngoecele
- vocal cord palsy (due to trauma or Arnold-Chiari malformation)
- glottic web
- subglottic stenosis
- laryngeal cleft
- tracheal
  - tracheoesophageal fistula
  - tracheomalacia
  - vascular rings
- 2-3 Months
  - congenital
    - laryngomalacia
    - vascular: subglottic hemangioma (more common), innominate artery compression, double aortic arch
    - laryngeal papilloma
  - acquired
    - subglottic stenosis: post-intubation
    - tracheal granulation: post-intubation
    - tracheomalacia: post-tracheotomy and TEF repair
- Infants – Sudden Onset
  - foreign body aspiration
  - croup
  - bacterial tracheitis
  - caustic ingestion
  - epiglottitis
- Children and Adults
  - infection
    - Ludwig's angina
    - peritonsillar/parapharyngeal abscess
    - retropharyngeal abscess
  - neoplastic
    - squamous cell carcinoma (SCC) (adults): larynx, hypopharynx
    - retropharyngeal: lymphoma, neuroblastoma
    - nasopharyngeal: carcinoma, rhabdomyosarcoma
  - allergic
    - angioneurotic edema
    - polyps (suspect cystic fibrosis in children)
  - trauma
    - laryngeal fracture, facial fracture
    - burns and lacerations
    - post-intubation
    - caustic ingestion
  - congenital
    - lingual thyroid/tonsil

**Signs of Airway Obstruction**

**Stridor**
- note quality, timing (inspiratory or expiratory)
- body position important
  - lying prone: subglottic hemangioma, double aortic arch
  - lying supine: laryngomalacia, glossoptosis
- site of stenosis
  - vocal cords or above: inspiratory stridor
  - subglottis and extrathoracic trachea: biphasic stridor
  - distal tracheobronchial tree: expiratory stridor

**Respiratory Distress**
- nasal flaring
- supraclavicular and intercostal indrawing
- sternal retractions
- use of accessory muscles of respiration
- tachypnea
- cyanosis
- altered LOC
Feeding Difficulty and Aspiration
- supraglottic lesion
- laryngomalacia
- vocal cord paralysis
- laryngeal cleft → aspiration pneumonia

Acute Laryngotracheobronchitis (Croup)
- inflammation of tissues in subglottic space ± tracheobronchial tree
- swelling of mucosal lining and associated with thick, viscous, mucopurulent exudate which compromises upper airway (subglottic space narrowest portion of upper airway)
- normal function of ciliated mucous membrane impaired

**Etiology**
- viral: parainfluenzae I (most common), II, III, influenza A and B, RSV

**Clinical Features**
- age: 4 mo-5 yr
- preceded by URTI symptoms
- generally occurs at night
- biphasic stridor and croupy cough (loud, sea-lion bark)
- appear less toxic than epiglottitis
- supraglottic area normal
- rule out foreign body and subglottic stenosis
- “steeple-sign” on AP x-ray of neck
- if recurrent croup, think subglottic stenosis

**Treatment**
- racemic epinephrine via MDI q1-2h, prn (only if in respiratory distress)
- systemic corticosteroids (e.g. dexamethasone, prednisone)
- adequate hydration
- close observation for 3-4 h
- intubation if severe
- consider alternate diagnosis if poor response to therapy (e.g. bacterial tracheitis)
- if recurrent episodes of croup-like symptoms, consider bronchoscopy several weeks after acute episode settles to rule out underlying subglottic stenosis

Acute Epiglottitis
- acute inflammation causing swelling of supraglottic structures of the larynx without involvement of vocal cords

**Etiology**
- H. influenzae type b
- relatively uncommon condition due to Hib vaccine

**Clinical Features**
- any age, most commonly 1-4 yr
- rapid onset
- cyanotic/pale, inspiratory stridor, slow breathing, lungs clear with decreased air entry
- prefers sitting up (“tripod” posture), open mouth, drooling, tongue protruding, sore throat, dysphagia

**Investigations and Management**
- investigations and physical exam may lead to complete obstruction, thus preparations for intubation or tracheotomy must be made prior to any manipulation
- stat ENT/anesthesia consult(s)
- WBC (elevated), blood and pharyngeal cultures after intubation
- lateral neck radiograph (only done if patient stable)

**Treatment**
- secure airway
- IV access with hydration
- antibiotics: IV cefuroxime, cefotaxime, or ceftriaxone
- moist air
- extubate when leak around tube occurs and afebrile
- watch for meningitis
Subglottic Stenosis

Congenital
- diameter of subglottis < 4 mm in neonate (due to thickening of soft tissue of subglottic space or maldevelopment of cricoid cartilage)

Acquired
- following prolonged, repeated, or traumatic intubation
  - most commonly due to endotracheal intubation; nasal intubation is less traumatic and preferred in long-term intubation as it puts less pressure on the subglottis (tube sits at different orientation) and there is less movement
  - subglottic stenosis is related to duration of intubation and pressure of the endotracheal tube cuff
  - can also be due to foreign body, infection (e.g., TB, diphtheria, syphilis), or chemical irritation

Clinical Features
- biphasic stridor
- respiratory distress
- recurrent/prolonged croup

Diagnosis
- rigid laryngoscopy and bronchoscopy

Treatment
- if soft stenosis: divide tissue with knife or laser, dilate with balloon ± steroids
- if firm stenosis: laryngotracheoplasty

Laryngomalacia

- short aryepiglottic folds, omega-shaped epiglottis, pendulous mucosa
- caused by indrawing of supraglottis on inspiration leading to laryngopharyngeal reflux of acid

Clinical Features
- high-pitched inspiratory stridor at 1-2 wk
- constant or intermittent and more pronounced supine and following URTI
- usually mild but when severe can be associated with cyanosis or feeding difficulties, leading to failure to thrive

Treatment
- observation is usually sufficient as symptoms spontaneously subside by 12-18 mo in >90% of cases
- if severe, division of the aryepiglottic folds (supraglottoplasty) provides relief

Foreign Body

Ingested
- usually stuck at cricopharyngeus
- coins, toys, batteries (emergency)
- presents with drooling, dysphagia, stridor if very large

Aspirated
- usually stuck at right mainstem bronchus
- peanuts, carrot, apple core, popcorn, balloons
- presentation
  - stridor if lodged in trachea
  - unilateral “asthma” if bronchial, therefore often misdiagnosed as asthma
  - if totally occludes airway: cough, lobar pneumonia, atelectasis, mediastinal shift, pneumothorax, death

Diagnosis and Treatment
- any patient with suspected foreign body should be kept NPO immediately
- inspiration-expiration chest x-ray (if patient is stable)
- bronchoscopy or esophagoscopy with removal
- rapid onset, not necessarily febrile or elevated WBC

Foreign body inhalation is the most common cause of accidental death in children

Laryngomalacia is the most common cause of stridor in infants

Batteries MUST be ruled out as a foreign body (vs. coins) as they are lethal and can erode through the esophagus. Batteries have a halo sign around the rim on AP x-ray and a step deformity on lateral x-ray

Laryngomalacia is the most common cause of stridor in infants
Deep Neck Space Infection

- most commonly arise from an infection of the mandibular teeth, tonsils, parotid gland, deep cervical lymph nodes, middle ear, or the sinuses
- often a rapid onset and may progress to fatal complications

Etiology
- usually mixed aerobes and anaerobes that represent the flora of the oral cavity, upper respiratory tract, and certain parts of the ears and eyes

Clinical Features
- sore throat or pain and trismus
- dysphagia and odynophagia
- stridor and dyspnea
- late findings may include dysphonia and hoarseness
- swelling of the face and neck, erythema
- asymmetry of the oropharynx with purulent oral discharge
- lymphadenopathy

Diagnosis
- lateral cervical view plain radiograph
- CT
- MRI

Treatment
- secure the airway
- surgical drainage
- maximum doses of IV systemic antimicrobials regimens according to the site of infection

Common Medications

Table 21. Antibiotics

<table>
<thead>
<tr>
<th>Generic Name (Brand Name)</th>

**Primary Care**

### Visit Overview

- **schedule:**
  - newborn (within 1 wk post-discharge), 1, 2, 4, 6, 9, 12, 15, 18, 24 mo
  - annually between age 2 to 6; every other year between age 6 to 11
- **content:**
  - history and physical exam including growth, development, and nutrition
  - routine immunizations
  - counseling and anticipatory guidance

IM = intramuscular; PO = per oral; SC = subcutaneous, *starting at 6 mo of age, † 2 dose series (second dose given 6-18 mo after first)
Growth and Development

Growth

- growth is not linear
- tissues grow at different times
  - first two years = CNS; mid-childhood = lymphoid tissue; puberty = gonads
- measurement of growth
  - premature infants (<37 wk) use corrected GA until age 2 yr
  - body proportion = upper/lower segment ratio (use symphysis pubis as midpoint)
    - newborn = 1.7, adult male = 0.9, adult female = 1.0

Vaccine Administration

- injection site
  - infants (<12 mo): anterolateral thigh
  - children: deltoid, subcutaneous tissue of the upper triceps area of the arm (IM injections should be given at 90° angle; SC injections should be given at 45° angle)
- timing of injection
  - varicella and MMR vaccines can be given at either the same visit or separated by >4 wk (MMRV at 4-6 yr)
  - HPV vaccine given in 3 doses to all adolescents aged 11-12 yr old (HPV-2 or HPV-4 for females; only HPV-4 for males) (0, 2, 6 mo)
### Average Growth Parameters

#### Table 3. Parameter of Average Growth at Birth

</tr>
<tr>
<td></td>
<td></td>
<td>0.5 cm/mo at 6-12 mo</td>
<td></td>
</tr>
</tbody>
</table>

**Normal Growth Comments**
- Weight loss (up to 10% of birth weight) in first 7 d of life is normal
- Neonate should regain birth weight by ~10-14 d of age
- Weight loss (up to 10% of birth weight) in first 7 d of life is normal
- Neonate should regain birth weight by ~10-14 d of age
- Measure supine length until 2 yr of age, then measure standing height

### Reflexes

#### Table 4. Reflexes

<table>
<thead>
<tr>
<th>Reflex</th>
<th>Maneuver to Elicit Reflex</th>
<th>Appropriate Reflex Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>Moro</td>
<td>Infant placed semi-upright, head supported by examiner’s hand, sudden withdrawal of supported head with immediate return of support</td>
<td>Abduction and extension of the arms, opening of the hands, followed by flexion and adduction of arms</td>
</tr>
<tr>
<td>Galant</td>
<td>Infant held in ventral suspension and one side of back is stroked along paravertebral line</td>
<td>Pelvis will move in the direction of stimulated side</td>
</tr>
<tr>
<td>Grasp</td>
<td>Placement of examiner’s finger in infant’s palm</td>
<td>Flexion of infant’s fingers</td>
</tr>
<tr>
<td>ATNR</td>
<td>Turn infant’s head to one side</td>
<td>“Fencing” posture (extension of ipsilateral leg and arm and flexion of contralateral arm)</td>
</tr>
<tr>
<td>Placing</td>
<td>Dorsal surface of infant’s foot placed touching edge of table</td>
<td>Flexion followed by extension of ipsilateral limb up onto table (resembles primitive walking)</td>
</tr>
<tr>
<td>Rooting</td>
<td>Tactile stimulus near mouth</td>
<td>Infant pursues stimulus with face</td>
</tr>
<tr>
<td>Parachute</td>
<td>Infant to side while in sitting position</td>
<td>Ipsilateral arm extension, present by 6-8 mo</td>
</tr>
</tbody>
</table>

**Abnormal Reflex Response**
- Absence may suggest CNS abnormality
- Persistence after 4-6 mo may indicate abnormality (e.g. cerebral palsy)
- Asymmetry suggests focal motor lesions (e.g. brachial plexus injury)
- Upgoing plantar reflex (Babinski’s sign) normal in infants up to age 2 yr

### Developmental Milestones

#### Table 5. Developmental Milestones

<table>
<thead>
<tr>
<th>Age*</th>
<th>Gross Motor</th>
<th>Fine Motor</th>
<th>Speech and Language</th>
<th>Adaptive and Social Skills</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 mo</td>
<td>Turns head side to side when supine</td>
<td>Hands fist, thumb in fist</td>
<td>Cries, startles to loud noises</td>
<td>Calms when comforted</td>
</tr>
<tr>
<td></td>
<td>Briefly raises head when prone, holds head erect when upright</td>
<td>Pulls at clothes</td>
<td>Variety of sounds (e.g. coos, gurgles)</td>
<td>Smiles responsively, recognizes and calms down to familiar voice, follows movement with eyes</td>
</tr>
<tr>
<td>4 mo</td>
<td>Lifts head and chest when prone, holds head steady when supported sitting, rolls prone to supine</td>
<td>Briefly holds object when placed in hand, reaches for midline objects</td>
<td>Turns head towards sounds</td>
<td>Laughs responsively, follows moving toy or person with eyes, responds to people with excitement (e.g. leg movement)</td>
</tr>
<tr>
<td>6 mo</td>
<td>Tripod sit, pivots in prone position</td>
<td>Ulnar or raking grasp, transfers objects from hand to hand, brings objects to mouth</td>
<td>Babbles</td>
<td>Stranger anxiety, beginning of object permanence</td>
</tr>
<tr>
<td>9 mo</td>
<td>Sits well without support, crawls, pulls to stand, stands with support</td>
<td>Early pincer grasp with straight wrist</td>
<td>“Mama, dada” -- appropriate, imitates 1 word, responds to “no” regardless of tone</td>
<td>Plays games (e.g. peek-a-boo), reaches to be picked up</td>
</tr>
<tr>
<td>12 mo</td>
<td>Gets into sitting position without help, stands without support, walks while holding on</td>
<td>Neat pincer grasp, releases ball with throw</td>
<td>2 words, follows 1-step command, uses facial expression, sounds, actions to make needs known</td>
<td>Responds to own name, separation anxiety begins</td>
</tr>
</tbody>
</table>

*Use corrected GA until 2 yr

### Scoliosis Screening

Despite mass school screening implemented in parts of the USA and Canada in the 1970s-90s, the Canadian (1994) and American (2004) Task Forces on Preventive Health Care do NOT currently recommend routine screening using the Forward Bend Test (FBT). Cohort studies indicate that the Forward Bend Test has poor sensitivity for identifying pathological curves. Furthermore, there is no evidence to suggest that screening and increased bracing lead to better outcomes.

### Pediatric Developmental Milestones

- 1 yr: single words
- 2 yr: 2-word sentences; understands 2 step commands
- 3 yr: 3-word combinations; rides tricycle
- 4 yr: counts 4 objects
- See the Nipissing District Developmental Screen for a checklist of important 18 mo milestones: http://www.ndds.ca

**ATNR** = asymmetric tonic neck reflex
### Table 5. Developmental Milestones (continued)

<table>
<thead>
<tr>
<th>Age*</th>

<th>Fine Motor</th>
<th>Speech and Language</th>
<th>Adaptive and Social Skills</th>
</tr>
</thead>
<tbody>
<tr>
<td>15 mo</td>
<td>Walks without support, crawls up stairs/steps</td>
<td>Picks up and eats finger foods, scribbles, stacks 2 blocks</td>
<td>Says 4-5 words, points to needs/wants</td>
<td>Looks to see how others react (e.g. after falling)</td>
</tr>
<tr>
<td>18 mo</td>
<td>Runs, walks forward pulling toys or carrying objects</td>
<td>Tower of 3 cubes, scribbling, eats with spoon</td>
<td>10 words, follows simple commands</td>
<td>Shows affection towards others, points to show interest in something</td>
</tr>
<tr>
<td>24 mo</td>
<td>Climbs up 2 feet per step, runs, kicks ball, walks up and down stairs</td>
<td>Tower of 6 cubes, undresses</td>
<td>2-3 word phrases, uses &quot;I, me, you&quot;, 50% intelligible, understands 2-step commands</td>
<td>Parallel play, helps to dress</td>
</tr>
<tr>
<td>3 yr</td>
<td>Tricycle, climbs up 1 foot per step, down 2 feet per step, stands on one foot briefly</td>
<td>Copies a circle, turns pages one at a time, puts on shoes, dress/undress fully except buttons</td>
<td>Combines 3 or more words into sentence, recognizes colors, prepositions, plurals, counts to 10, 75% intelligible</td>
<td>Knows sex and age, shares some of the time, plays make-believe games</td>
</tr>
<tr>
<td>4 yr</td>
<td>Hops on 1 foot, down 1 foot per step</td>
<td>Copies a cross, uses scissors, buttons clothes</td>
<td>Speech 100% intelligible, uses past tense, understands 3-part directions</td>
<td>Cooperative play, fully toilet-trained by day, tries to comfort someone who is upset</td>
</tr>
<tr>
<td>5 yr</td>
<td>Skips, rides bicycle</td>
<td>Copies a triangle and square, prints name, ties shoelaces</td>
<td>Fluent speech, future tense, alphabet, retells sequence of a story</td>
<td>Cooperates with adult requests most of the time, separates easily from caregiver</td>
</tr>
</tbody>
</table>

*Use corrected GA until 2 yr

### Nutrition

#### Dietary Requirements

<table>
<thead>
<tr>
<th>Weight</th>
<th>Needs</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;10 kg</td>
<td>100 kcal/kg/d</td>
</tr>
<tr>
<td>10-20 kg</td>
<td>1,000 cal + 50 kcal/kg/d for each kg &gt;10</td>
</tr>
<tr>
<td>&gt;20 kg</td>
<td>1,500 cal + 20 kcal/kg/d for each kg &gt;20</td>
</tr>
</tbody>
</table>

#### Dietary Recommendations

- **0-6 mo**: breast milk or formula
  - exclusive breast milk during first 6 mo recommended over formula unless contraindicated
  - breastfed infants require supplements: vitamin K (all babies get at birth, breastfed or not), vitamin D (400-800 IU/d), fluoride (after 6 mo if not sufficient in water), iron (6-12 mo, only if not receiving fortified cereals/meat/meat alternatives)
- **>6 mo**: solid food introduction – do not delay beyond 9 mo
  - 2-3 new foods per week with a few days in between each food to allow time for adverse reaction identification
  - suggested order of introduction
    - meat, meat alternatives, and iron-enriched cereal (rice cereal is least allergic)
    - pureed vegetables
    - fruit
- **9-12 mo**: finger foods and switch to homogenized (3%) milk
  - foods to avoid
    - honey until past 12 mo (risk of botulism)
    - added sugar, salt
    - excessive milk (i.e. no more than 16 oz/d after 1 yr)
    - juice (not nutritious, too much sugar)
    - anything that is a choking hazard (chunks, round foods like grapes)

#### Breastfeeding

- **content of breast milk**
  - colostrum (first few days): clear, rich in nutrients (i.e. high protein, low fat), immunoglobulin
  - mature milk: 70:30 whey:casein ratio, fat from dietary butterfat, carbohydrate from lactose
- **advantages**
  - easily digested, low renal solute load
  - immunologic
    - contains IgA, macrophages, active lymphocytes, lysozymes, lactoferrin (which inhibits *E. coli* growth in intestine)
    - lower pH promotes growth of lactobacillus in GI tract
  - parent-child bonding
  - economical, convenient
• contraindicated if mother
  ▪ is receiving chemotherapy or radioactive compounds
  ▪ has HIV/AIDS, active untreated TB, herpes in breast region
  ▪ is using >0.5 g/kg/d of alcohol or illicit drugs
  ▪ is taking medications known to cross to breast milk
  ▪ OCPs are not a contraindication to breastfeeding (estrogen may decrease lactation, but is not dangerous to infant)
  ▪ MotherRisk – valuable research and counseling on reproductive risk or safety of drugs and chemicals

• complications in infant
  ▪ breastfeeding jaundice (first 1-2 wk): due to lack of maternal milk production and subsequent infant dehydration (see jaundice, P72), likely a mechanical problem
  ▪ breast milk jaundice (0.5% of newborns, persists up to 4-6 mo): rare, not fully understood, thought to be due to substances in breast milk that inhibit conjugation of bilirubin or increase enterohepatic circulation of bilirubin, likely a biochemical problem; check bilirubin to rule out conjugated hyperbilirubinemia
  ▪ baby presents healthy and thriving, and jaundice resolves
  ▪ poor weight gain: consider dehydration or FTT
  ▪ oral candidiasis (thrush): check baby’s mouth for white cheesy material that does not scrape off; treat baby with antifungal such as nystatin (Mycostatin®); can occur in breast or bottle-fed infants

Table 6. Common Formulas Compared to Breast Milk

<table>
<thead>
<tr>
<th>Type of Nutrition</th>
<th>Indications</th>
<th>Content (as compared to breast milk)</th>
</tr>
</thead>
</table>
| Cow’s Milk Based (Enfamil®, Similac®) | Prematurity | Transition into breastfeeding
| Fortified Formula | Low birth weight | Lower whey:casein ratio
| Soy Protein (Isomil®, Prosobee®) | Cow milk protein Intolerance/allergy | Corn syrup solids or sucrose in place of lactose
| Partially Hydrolyzed Proteins (Good Start®) | Delayed gastric emptying | Protein is 100% whey with no casein
| Protein Hydrolysate (Nutramigen®, Alimentum®, Pregestimil®, Portagen®) | Malabsorption Food allergy | Protein is 100% casein with no whey
| Amino Acid (Neocate®, PurAminoTM) | Short gut | Free amino acids (no protein)
| Metabolic | Inborn errors of metabolism | Various different compositions for children with galactosemia, propionic academia, etc.

Injury Prevention Counseling

• injuries are the leading cause of death in children >1 yr of age
• main causes: motor vehicle accidents, burns, drowning, falls, choking, infanticide

Table 7. Injury Prevention Counseling

<table>
<thead>
<tr>
<th>0-6 mo</th>
<th>6-12 mo</th>
<th>1-2 yr</th>
<th>2-5 yr</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do not leave alone on bed, on changing table, or in tub Keep crib rails up Check water temperature before bathing Do not hold hot liquid and infant at the same time Check milk temperature before feeding</td>
<td>Install stair barriers Discourage use of walkers Avoid play areas with sharp-edged tables and corners Cover electrical outlets Unplug appliances when not in use Keep small objects, plastic bags, cleaning products, and medications out of reach</td>
<td>Never leave unattended Keep pot handles turned to back of stove Caution with whole grapes, nuts, raw carrots, hotdogs, etc. due to choking hazard No running while eating</td>
<td>Bicycle helmet Never leave unsupervised at home, driveway, or pool Teach bike safety, stranger safety, and street safety Swimming lessons (&gt;4 yr), sunscreen (from 6 mo), fences around pools</td>
</tr>
</tbody>
</table>

Note: This list is not exhaustive. For more details, see Rourke Baby Record (http://www.rourkebabyrecord.ca/pdf/RBR2010Ort_Eng.pdf)
Common Complaints

Breath Holding Spells

- epidemiology: 0.1-5% of healthy children 6 mo–4 yr of age, usually start during first year of life
- etiology: child is provoked (usually by anger, injury, or fear) → holds breath and becomes silent
  → spontaneously resolves or loses consciousness
- types
  - cyanotic (more common), usually associated with anger/frustration
  - pallid, usually associated with pain/surprise
- management
  - usually resolves spontaneously and rarely progresses to seizure
  - help child control response to frustration and avoid drawing attention to spell

Circumcision

- elective procedure
  - recent evidence shows health benefits outweigh risks and justify access to procedure
  - often for religious or culture reasons
- benefits: prevention of phimosis and slightly reduced incidence of UTI, STD, balanitis, cancer of the penis
- complications (<1%): local infection, bleeding, urethral injury
- contraindications: presence of genital abnormalities (e.g. hypospadias) or known bleeding disorder

Crying/Fussing Child

- history
  - description of baseline feeding, sleeping, crying patterns
  - infectious symptoms: fever, tachypnea, rhinorrhea, ill contacts
  - feeding intolerance: gastroesophageal reflux with esophagitis, N/V, diarrhea, constipation
  - trauma
  - recent immunizations (vaccine reaction) or medications (drug reactions), including maternal drugs taken during pregnancy (neonatal withdrawal syndrome) and drugs that may be transferred via breast milk
  - inconsistent history, pattern of numerous emergency department visits, high-risk social situations all raise concern of maltreatment

Table 8. Physical Exam and Differential Diagnosis

</tbody>
</table>
Infantile Colic

- definition: unexplained paroxysms of irritability and crying for >3 h/d, >3 d/wk for >3 wk in an otherwise healthy, well-fed baby (rule of 3s)
- epidemiology: 10% of infants; usual onset 10 d to 3 mo of age with peak at 6-8 wk
- etiology: lag in development of normal peristaltic movement in gastrointestinal tract; other theories suggest a lack of self-soothing mechanisms or extreme of normal
- management
  - parental relief, rest, and reassurance
  - hold baby, pacifier, car ride, music, vacuum, check diaper
  - medications (Ovol® drops, gripe water) have no proven benefit, some evidence for probiotics
  - if breastfeeding, elimination of cow’s milk protein from mother’s diet (effective in very small percentage of cases)
  - try casein hydrolysate formula (Nutramigen®)
  - time – all resolve, most in the first 2-3 mo of life

Dentition and Caries

Dentition
- primary dentition (20 teeth)
  - first tooth at 5-9 mo (lower incisor), then 1/mo
  - 6-8 central teeth by 1 yr
  - assessment by dentist 6 mo after eruption of first tooth and certainly by 1 yr of age (Grade B recommendation)
- secondary dentition (32 teeth)
  - first adult tooth is 1st molar at 6 yr, then lower incisors

Caries
- milk caries: decay of superior front teeth and back molars in first 4 yr of life
- cause: often due to prolonged feeding (e.g. put to bed with bottle, prolonged breastfeeding)
- prevention
  - no bottle at bedtime, clean teeth after last feed
  - minimize juice and sweetened pacifier
  - clean teeth with soft damp cloth or toothbrush and water
  - water fluoridation

Enuresis

Definition
- involuntary urinary incontinence by day and/or night in child >5 yr

General Approach
- should be evaluated if dysuria, change in color, odor, stream, secondary or diurnal, change in gait, stool incontinence

Primary Nocturnal Enuresis
- definition: involuntary loss of urine at night, bladder control has never been attained
- epidemiology: M>F; 10% of 6 yr olds, 3% of 12 yr olds, 1% of 18 yr olds
- etiology: developmental disorder or maturational lag in bladder control while asleep
- management
  - time and reassurance (~20% resolve spontaneously each yr)
  - behavior modification (limiting fluids, voiding prior to sleep), bladder retention exercises, scheduled toileting overnight has limited effectiveness
  - conditioning: “wet” alarm wakes child upon voiding (70% success rate)
  - medications (considered second line therapy, may be used for sleepovers/camp): DDAVP oral tablets (high relapse rate, costly), imipramine (Tofranil®) (rarely used, lethal if overdose, cholinergic side effects)

Secondary Enuresis
- definition: involuntary loss of urine at night, develops after child has sustained period of bladder control (>6 mo)
- etiology: inorganic regression due to stress or anxiety (e.g. birth of sibling, significant loss, family discord), focused on other activities, secondary to organic disease (UTI, DM, DI, neurogenic bladder, CP, seizures, pinworms)
- management: treat underlying cause

Antidiuretic Hormone Regulation in Primary Nocturnal Enuresis
Arch Dis Child 1995;73(6):508-11
Treatment of primary nocturnal enuresis using DDAVP is based upon the hypothesis that ADH secretion is insufficient at night. The known efficacy of the treatment on the one hand, and persisting doubts about its theoretical basis on the other, formed the background of the present study. Ten children (mean age 10.5 yr) with primary nocturnal enuresis were compared with a corresponding control group of eight patients. Diurnal and nocturnal urine production, ADH secretion, and plasma osmolality were determined. No differences between the two groups were found for urine production, ADH levels during day and night, or plasma osmolality. However, in order to regulate plasma osmolality the enuretic children required a markedly greater output of ADH: 2.87 pg/ml/mmol/kg compared with 0.56 in the controls (p < 0.01). The results are consistent with the established fact that ADH secretion is a function of plasma osmolality, and they contradict the hypothesis that urine production is increased at night in enuretics because of lower ADH secretion.
Diurnal Enuresis
- definition: daytime wetting (60-80% also wet at night)
- etiology: micturition deferral (holding urine until last minute) due to psychosocial stressor (e.g. shy), structural anomalies (e.g. ectopic ureteral site, neurogenic bladder), UTI, constipation, CNS disorders, DM
- management: treat underlying cause, behavioral (scheduled toileting, double voiding, good bowel program), pharmacotherapy

Encopresis
- definition: fecal incontinence in a child >4 yr old, at least once per mo for 3 mo
- prevalence: 1-1.5% of school-aged children (rare in adolescence); M:F = 6:1 in school-aged children
- causes: chronic constipation (retentive encopresis), Hirschsprung disease, hypothyroidism, hypercalcemia, spinal cord lesions, anorectal malformations, bowel obstruction

Retentive Encopresis
- definition: child holds bowel movement, develops constipation, leading to fecal impaction and seepage of soft or liquid stool (overflow incontinence)
- etiology
  - physical: painful stooling often secondary to constipation
  - emotional: disturbed parent-child relationship, coercive toilet training, social stressors
- clinical presentation
  - history
    - crosses legs or stands on toes to resist urge to defecate
    - distressed by symptoms, soiling of clothes
    - toilet training coercive or lacking in motivation
    - may show oppositional behavior
    - abdominal pain
  - physical exam
    - digital rectal exam: large fecal mass in rectal vault
    - anal fissures (result from passage of hard stools)
    - palpable stool in LLQ
- management
  - complete clean-out of bowel: PEG 3350 given orally is most effective, enemas and suppositories may be second line therapies, but these are invasive and often less effective
  - maintenance of regular bowel movements (see Pediatric Gastroenterology, Constipation Treatment, P38)
  - assessment and guidance regarding psychosocial stressors
  - behavioral modification
- complications: recurrence, toxic megacolon (requires >3-12 mo to treat), bowel perforation

Toilet Training
- 90% of children attain bladder control before bowel control
- generally, females train earlier than males
- 25% by 2 yr (in North America), 98% by 3 yr have daytime bladder control
- signs of toilet readiness
  - ambulating independently, stable on potty, desire to be independent or to please caregivers (i.e. motivation), sufficient expressive and receptive language skills (2-step command level), can stay dry for several hours [large enough bladder], can recognize need to go, able to remove clothing

Failure to Thrive
- definition
  - weight <3rd percentile, falls across two major percentile curves, or <80% of expected weight for height and age
  - inadequate caloric intake most common factor in poor weight gain
  - may have other nutritional deficiencies (e.g. protein, iron, vitamin D)
  - factors affecting physical growth: genetics, intrauterine factors, internal time clock, nutrition, endocrine hormones, chronic infections/diseases, psychosocial factors
- clinical presentation
  - history
    - nutritional intake
    - current symptoms
    - past illnesses

Energy Requirements
- 0-10 kg: 100 kcal/kg/d
- 10-20 kg: 1,000 kcal + 50 kcal/kg/d for each kg >10
- > 20 kg: 1,500 kcal + 20 kcal/kg/d for each kg >20
- family history: growth, puberty, parental height and weight including mid-parental height
- psychosocial history
- physical exam
  - growth parameters, plotted: height, weight, head circumference, arm span
  - vital signs
  - complete head to toe exam
  - dysmorphic features or evidence of chronic disease
  - upper to lower segment ratio
  - sexual maturity staging
  - signs of maltreatment or neglect
- investigations (as indicated by clinical presentation)
  - CBC, blood smear, electrolytes, T4, TSH
  - bone age x-ray
  - chromosomes/karyotype
  - chronic illness: chest (CXR, sweat Cl-), cardiac (CXR, ECG, Echo), GI (celiac screen, inflammatory markers, malabsorption), renal (urinalysis), liver (enzymes, albumin)

| Decreased Wt       | Decreased Ht, Normal HC               |
|                   | Structural dysphagia                   |
|                   | Endocrine disorder                    |
|                   | Constitutional growth delay (BA < CA)  |
|                   | Familial short stature (BA = CA)       |

| Decreased Wt       | Decreased Ht, Decreased HC            |
|                   | Intrauterine insult                   |
|                   | Genetic abnormality                   |

- Non-Organic FTT (90%)
  - most common cause of FTT
  - results from complex factors in parent-child relationship
    - dietary intake, knowledge about feeding, improper mixing of formula, economic factors
    - feeding environment
    - parent-child interaction, attachment
    - child behaviors, hunger/satiety cues
    - social factors: stress, poverty
    - management
      - most as outpatient using multidisciplinary approach: primary care physician, dietitian, psychologist, social work, Child Protection Services
      - medical: oromotor problems, iron-deficiency anemia, gastroesophageal reflux
      - nutritional: educate about age-appropriate foods, calorie boosting, mealtimes schedules and environment to reach goal of 90-110% IBW, correct nutritional deficiencies, and promote catch-up growth/development
      - behavioral: positive reinforcement, mealtimes environment

- Organic FTT (10%)
  - inadequate intake: vomiting, oromotor dysfunction, anorexia
  - excessive consumption: CHD, CF, hyperthyroidism
  - abnormal utilization: inborn errors of metabolism
  - excessive output: IBD, celiac, malabsorption
  - management: treat specific cause

### Energy Requirements
- see Nutrition, P6

### Obesity
- definition: BMI >95th percentile for age and height
- risk factors: genetic predisposition (e.g. both parents obese ~ 80% chance of obese child)
- etiology: organic causes are rare (<5%), but may include Prader-Willi, Carpenter, Turner, Cushing syndromes, hypothyroidism
- complications: association with HTN, dyslipidemia, slipped capital femoral epiphysis, type 2 DM, asthma, obstructive sleep apnea, gynecomastia, polycystic ovarian disease, early menarche, irregular menses, psychological trauma (e.g. bullying, decreased self-esteem, unhealthy coping mechanisms, depression)
- childhood obesity is not reliable predictor of adult obesity unless >180% of IBW; adolescent obesity good predictor of adult obesity
- management
  - encouragement and reassurance; engagement of entire family

#### Upper to Lower Segment Ratio
- Increased in achondroplasia, short limb syndromes, hypothyroid, storage diseases
- Decreased in Marfan’s, Klinefelter’s, Kallman’s syndromes, and testosterone deficiency
- Calculation: upper segment/lower segment
  - Upper segment: top of head to pubic symphysis
  - Lower segment: pubic symphysis to floor

#### Mid-Parental Height
- Boys: Target height = (father ht + mother ht + 13) / 2
- Girls: Target height = (father ht + mother ht – 13) / 2

Note: height should be taken in cm

#### Clinical Signs of FTT
- SMALL KID
  - Subcutaneous fat loss
  - Muscle atrophy
  - Alopecia
  - Leukopeny
  - Lagging behind normal
  - Kavashorker
  - Infection (recurrent)
  - Dermatitis

**Objective:** To examine the prevalence of obesity and severe obesity over time for 14 yr of the continuous National Health and Nutrition Examination Survey, 1999-2012, and to examine differences in the trends by age, race/ethnicity, and sex.

**Participants:** Representative sample (N = 26,690) of children in the United States, ages 2-19 yr, in repeated cross-sections of the National Health and Nutrition Examination Survey, 1999-2012.

**Main Outcomes:** Prevalence of overweight (body mass index [BMI] ≥ 85th percentile), obesity (BMI ≥ 95th percentile for age and sex), class 2 obesity (BMI ≥ 120% of the 95th percentile or BMI ≥ 35), and class 3 obesity (BMI ≥ 140% of the 95th percentile or BMI ≥ 40).

**Results:** From 2001-2012, 13.3% of children in the United States aged 2-19 yr were obese. Additionally, 5.9% of children met criteria for class 2 obesity and 2.1% met criteria for class 3 obesity. Although these rates were not significantly different from 2009-2010, all classes of obesity have increased over the last 14 yr.

**Conclusions:** Nationally representative data do not show any significant changes in obesity prevalence in the most recently available years, although the prevalence of obesity may be stabilizing.
diet: qualitative changes (do not encourage weight loss, but allow for linear growth to catch up with weight), special diets used by adults and very low calorie diets are not encouraged
behavior modification: increase activity, change eating habits/meal patterns
education: multidisciplinary approach, dietitian, counseling
surgery and pharmacotherapy are not frequently used in children
increase activity, reduce screen time

Poison Prevention

- keep all types of medicines, vitamins, and chemicals locked up in a secure container
- potentially dangerous: medications, illicit drugs, drain cleaners, furniture polish, insecticides, cosmetics, nail polish remover, automotive products
- do not store any chemicals in juice, soft drink, or water bottles
- keep alcoholic beverages out of reach: 3 oz hard liquor can kill a 2 yr old
- always read labels before administering medicine to ensure correct medication drug and dose and/or speak with a pharmacist or healthcare provider

Rashes

Table 10. Common Pediatric Rashes

<table>

Pediatric Exanthems (see Infectious Pediatric Exanthems, P57)

Drug Reactions (see Dermatology, D21)

Acne (see Dermatology, D11)
Sleep Disturbances

Types of Sleep Disturbances

- Insufficient sleep quantity
  - Difficulty falling asleep (e.g., limit setting sleep disorder)
  - Preschool and older children
  - Bedtime resistance
  - Due to caregiver's inability to set consistent bedtime rules and routines
  - Often exacerbated by child's oppositional behaviors

- Poor sleep quality
  - Frequent arousals (e.g., sleep-onset association disorder)
  - Infants and toddlers
  - Child learns to fall asleep only under certain conditions or associations (e.g., with parent, held, rocked or fed, with light on, in front of television), and loses ability to self-soothe
  - During the normal brief arousal periods of sleep (q90-120 min), child cannot fall back asleep because same conditions are not present

- Obstructive sleep apnea
  - Epidemiology: 1-5% of preschool aged children, more common in African American children
  - Definition: Partial or intermittent complete airway obstruction during sleep causing disrupted ventilation and sleep pattern
  - Features: Snoring/gasping/noisy breathing during sleep and irritable/tired/hyperactive during the day
  - Sequelae: Cardiovascular (HTN/LV remodeling due to sympathetic activation), growth, cognitive, and behavioral deficits
  - Risk factors: Adenotonsillar hypertrophy, obesity
  - Management: Watchful waiting, weight reduction, airway pressure devices, or surgery depending on the cause
  - Adenotonsillectomy does not improve executive function or attention but reduces symptoms and improves behavior, quality of life, and polysomnographic findings

- Parasomnias
  - Episodic nocturnal behaviors (e.g., sleepwalking, sleep terrors, nightmares)
  - Often involves cognitive disorientation and autonomic/skeletal muscle disturbance

Management of Sleep Disturbances

- Set strict bedtimes and "wind-down" routines
- Do not send child to bed hungry
- Positive reinforcement for: Limit setting sleep disorder
- Always sleep in own bed, in a dark, quiet, and comfortable room
- Do not use bedroom for timeouts
- Systematic ignoring and gradual extinction for: Sleep-onset association disorder

Nightmares

- Epidemiology: common in boys, 4-7 yr
- Associated with REM sleep (anytime during night)
- Features: Upon awakening, child is alert and clearly recalls frightening dream ± Associated with daytime stress/anxiety
- Management: Reassurance

Night Terrors

- Epidemiology: 15% of children have occasional episodes
- Abrupt sitting up, eyes open, screaming
- Clinical features: Occurs in early hours of sleep, stage 4 of sleep; signs of panic and autonomic arousal, no memory of event, inconsolable, stress/anxiety can aggravate them
- Course: Remits spontaneously at puberty
- Management: Reassurance for parents, ensure child is safe (e.g., if sleepwalks)

Sudden Infant Death Syndrome

Definition

- Sudden and unexpected death of an infant <12 mo of age in which the cause of death cannot be found by history, examination, or a thorough postmortem and death scene investigation

Epidemiology

- 0.5/1,000 (leading cause of death between 1-12 mo of age); M:F = 3:2
- More common in children placed in prone position
- In full term infants, peak incidence is 2-4 mo; 95% of cases occur by 6 mo
- Increase in deaths during peak RSV season
- Most deaths occur between midnight and 8 AM

Daily Sleep Requirement

</table>

Nap Patterns
**Risk Factors**

- prematurity, smoking in household, socially disadvantaged, higher incidence in Aboriginals and African Americans
- risk of SIDS is increased 3-5x in siblings of infants who have died of SIDS
- bedsharing: sleeping on a sofa, sleeping with an infant after consumption of alcohol/street drugs or extreme fatigue, infant sleeping with someone other than primary caregiver

**Prevention**

- "Back to Sleep, Front to Play" (place infant on back when sleeping)
- allow supervised play time daily in prone position ("tummy time")
- alarms, monitors not recommended – increase anxiety, do not prevent life-threatening events
- avoid overheating and overdressing
- appropriate infant bedding (e.g. firm mattress; avoid loose bedding, pillows, stuffed animals, and crib bumper pads)
- no smoking
- pacifiers appear to have a protective effect; do not reinsert if it falls out during sleep

---

**Child Abuse and Neglect**

**Definition**

- an act of commission (physical, sexual, or psychological abuse) or omission (neglect) by a caregiver that harms a child

**Legal Duty to Report**

- upon reasonable grounds to suspect abuse and/or neglect, physicians are required by legislation to contact the Child Protective Services (CPS) to personally disclose all information relevant to the child safety concern
- duty to report overrides patient confidentiality; physician is protected against liability

**Ongoing Duty to Report**

- if there are additional reasonable grounds to suspect abuse and/or neglect, a further report to the CPS must be made

**Risk Factors**

- environmental factors: social isolation, poverty, domestic violence
- caregiver factors: personal history of abuse, psychiatric illness, substance abuse, single parent family, poor social and vocational skills, below average intelligence
- child factors: difficult temperament, disability, special needs (e.g. developmental delay), premature

---

**Physical Abuse**

**History**

- history that is not compatible with physical findings, or history not reproducible
- delay in seeking medical attention that is unexplained by other factors

**Physical Exam**

- physical findings not explained by underlying medical condition
- growth parameters (weight, height, head circumference)
- recurrent or multiple injuries not explained by accidental injury or child’s development level
- patterned skin injuries: belt buckle, hand prints, burns that do not match provided history
- injury location: bruises on areas with abundant soft-tissue cushioning, such as abdomen, buttocks, genitalia, fleshy part of cheek; bruises on ears; posterior rib/metaphyseal/scapular/vertebral/sternal fractures (more suspicious for non-accidental injuries); immersion burns (e.g. hot water)
- altered mental status: head injury, poisoning
- head trauma is the leading cause of death in child maltreatment (e.g. acceleration-deceleration forces [shaking], direct force application [blow or impact])

**Investigations**

- document all injuries on a body diagram: type, location, size, shape, color, pattern
  - photography of skin injuries is ideal (police or hospital photography preferred; do not use physician's personal camera)
- blood tests to rule out medical causes (e.g. thrombocytopenia or coagulopathy)
- screen for abdominal trauma (transaminases and amylase): if increased, abdo CT recommended
- skeletal survey in children <2 yr
  - bone scan can be beneficial for assessing rib fractures (not helpful for skull or metaphyseal region due to active bone growth) – consider bone scan if equivocal findings on initial skeletal survey
  - dilated eye examination by pediatric ophthalmologist to rule out retinal hemorrhage
- be aware of “red herrings” (e.g. Mongolian blue spots vs. bruises)
- neuroimaging: CT and/or MRI

---

**Apparent Life-Threatening Events**

A group of conditions often marked by an episode of apnea, cyanosis, change in tone, or change in mental status occurring in a child, where an observer fears the child may be dying. There is no clear connection between most ALTEs and SIDS. Evaluating for a cause of the ALTE (e.g. infection, cardiac, neurologic) is guided by history, physical exam, and period of observation

**Presentation of Neglect**

- FTT, developmental delay
- Inadequate or dirty clothing, poor hygiene
- Child exhibits poor attachment to parents, no stranger anxiety

---

**If no cruising, no bruising**
Sexual Abuse

Epidemiology
• peak ages at 2-6 yr and 12-16 yr
• most perpetrators are male and known to child
  ▪ in decreasing order: family member, non-relative known to victim, stranger

History
• diagnosis usually depends on child disclosing to someone or forensic interview done by a
  trained individual
• psychosocial: specific or generalized fears, depression, nightmares, social withdrawal, lack of
  trust, low self-esteem, school failure, sexually aggressive behavior, advanced sexual knowledge,
  sexual preoccupation or play

Physical Exam
• recurrent UTIs, pregnancy, STDs, vaginitis, vaginal bleeding, pain, genital injury, enuresis

Investigations
• depend on presentation, age, sex, and pubertal development of child
  ▪ sexual assault examination kit within 24 h if prepubertal, within 72 h if pubertal
  ▪ rule out STD, UTI, pregnancy (consider STD prophylaxis or emergency contraception)
  ▪ rule out other injuries (vaginal/anal/oral penetration, fractures, head trauma)

Neglect

History
• from child and each caregiver separately (if possible)

Physical Exam
• head to toe (do not force), growth parameters, nutrition status
• dental care
• emotional state

Investigations
• blood tests to rule out medical conditions (e.g. thrombocytopenia or coagulopathy)

Management of Physical Abuse, Child Abuse, and Neglect
• report all suspicions to CPS; request emergency visit if imminent risk to child or any siblings in
  the home
• acute medical care: hospitalize for medical evaluation or treatment of injuries if indicated
• arrange consultation to social work and appropriate follow-up
• may need to discharge child directly to CPS or to responsible guardian under CPS supervision

Adolescent Medicine

Adolescent History (HEEADSSS)
• tailor your history according to the clinical context

Home: Who do you live with? What kind of place do you live in?

Education/Employment: What grade are you in? What are your favorite subjects? What was
your average on your last report card?

Eating: Tell me about your meals/snacks in a typical day. Have you ever gone on a diet?
(for Eating Disorders – see Psychiatry, PS26)

Activities: What do you do after school? On the weekends? How much time do you spend on
the computer/watching TV every day? Do you use social media (i.e. Facebook, Twitter, Instagram,
etc.)?

Drugs: Which seems to be more popular at your school, alcohol or drugs? How often do you
drink/smoke marijuana/take other drugs? Do you smoke cigarettes? When you drink, do you usu-
ally get drunk? Have you ever passed out or not been able to remember what happened while you
were drinking? Has anything bad ever happened to you while you were drunk or stoned?
(for Substance Abuse – see Psychiatry, PS18)

Sexuality: Are you romantically interested in anyone? When you think about having sex with
someone, do you think about girls, boys, or both? Have you ever had sex with anyone? Whether
the answer is yes or no, the next question is: What activities would you include in the term ‘having
sex’? What do you do to prevent getting a STD/getting pregnant/getting someone pregnant? Has
anyone ever given you money, drugs, or other stuff in exchange for sex? (for Sexually Transmitted
Diseases – see Gynecology, GY25)
Suicidality/Depression: On a scale of 1 to 10, where 1 is so sad that you might kill yourself and 10 is the happiest you could be, where are you most days? Is there a difference between school days and the weekend? Have you ever thought seriously about suicide? Did you make a plan? (for Depression/Suicide – see Psychiatry, PS7, PS2)

Safety/Violence: Do you ever get into a car with a driver who has been drinking? Do you always wear a seatbelt/bicycle helmet? Are you being bullied at school? Has anyone ever touched you in an unwanted way?

For Normal and Abnormal Pubertal Development, P31

Cardiology

Congenital Heart Disease

PRENATAL CIRCULATION

Embryologic Development
- most critical period of fetal heart development is between 3-8 wk gestation
- single heart tube grows rapidly, forcing it to bend back upon itself and assume the shape of a four chambered heart; insults at this time are most likely to lead to CHD

Before Birth
- fetal lungs are bypassed by flow through fetal shunts
  - shunting deoxygenated blood
    - ductus arteriosus: connection between pulmonary artery and aorta
  - shunting oxygenated blood
    - foramen ovale: connection between right and left atria
    - ductus venosus: connection between umbilical vein and inferior vena cava

At Birth
- with first breath, lungs open up → pulmonary resistance decreases → pulmonic blood flow increases
- separation of low resistance placenta → systemic circulation becomes a high resistance system → ductus venosus closure
- increased pulmonic flow → increased left atrial pressures → foramen ovale closure
- increased oxygen concentration in blood after first breath → decreased prostaglandins → ductus arteriosus closure
- closure of fetal shunts and changes in vascular resistance → infant circulation assumes normal adult flow
Epidemiology
- 8/1,000 live births have CHD, which may present as a heart murmur, heart failure, or cyanosis; VSD is the most common lesion

Investigations
- Echo, ECG, CXR
- pre and postductal oxygen saturations, 4 limb BPs, hyperoxia test

Cyanotic vs. Acyanotic Congenital Heart Disease
- cyanosis: blue mucous membranes, nail beds, and skin secondary to an absolute concentration of deoxygenated hemoglobin of at least 30 g/dL
- acyanotic heart disease (i.e. L to R shunt, obstruction occurring beyond lungs): blood passes through pulmonic circulation → oxygenation takes place → low levels of deoxygenated blood in systemic circulation → no cyanosis
- cyanotic heart disease (i.e. R to L shunt): blood bypasses the lungs → no oxygenation occurs → high levels of deoxygenated hemoglobin enters the systemic circulation → cyanosis

Acyanotic Congenital Heart Disease

1. Left-to-Right Shunt Lesions
- extra blood is displaced through a communication from the left to the right side of the heart → increased pulmonary blood flow → increased pulmonary pressures
- shunt volume is dependent upon three factors: (1) size of defect, (2) pressure gradient between chambers or vessels, and (3) peripheral outflow resistance
- untreated shunts can result in pulmonary vascular disease, left ventricular dilatation and dysfunction, right ventricular HTN and RVH, and ultimately R to L shunts

Atrial Septal Defect
- 3 types: ostium primum (common in DS), ostium secundum (most common type, 50-70%), sinus venosus (defect located at entry of superior vena cava into right atrium)
- epidemiology: 6-8% of congenital heart lesions
- natural history
  ▪ 80-100% spontaneous closure rate if ASD diameter <8 mm
  ▪ if remains patent, CHF and pulmonary HTN can develop in adult life
- clinical presentation
  ▪ history: often asymptomatic in childhood
  ▪ physical exam: grade 2-3/6 pulmonic outflow murmur, widely split and fixed S2
  ▪ children with large ASDs may have signs of heart failure (tachypnea, FTT, hepatomegaly, pulmonary rales/retractions)
- investigations
  ▪ ECG: RAD, mild RVH, RBBB
  ▪ CXR: increased pulmonary vasculature, cardiac enlargement
  ▪ Echo: test of choice
- management: elective surgical or catheter closure between 2-5 yr of age

Ventricular Septal Defect
- most common congenital heart defect (30-50%)
- small VSD (majority)
- clinical presentation
  ▪ history: asymptomatic, normal growth and development
  ▪ physical exam: early systolic to holosystolic murmur, best heard at LLSB, thrill
investigations: ECG and CXR are normal; Echo to confirm diagnosis
management: most close spontaneously
• moderate-to-large VSD
  epidemiology: CHF by 2 mo; late secondary pulmonary HTN if left untreated
  clinical presentation
    • history: delayed growth, decreased exercise tolerance, recurrent URTIs or “asthma” episodes
    • physical exam: holosystolic murmur at LL5B, mid-diastolic rumble at apex, size of VSD is inversely related to intensity of murmur
  investigations
    • ECG: LVH, LAH, RVH
    • CXR: increased pulmonary vasculature, cardiomegaly, CHF
    • Echo: diagnostic
  management: treatment of CHF and surgical closure by 1 yr old

Patent Ductus Arteriosus
• patent vessel between descending aorta and left pulmonary artery (normally, functional closure within first 15 h of life, anatomical closure within first days of life)
• epidemiology
  • 5-10% of all congenital heart defects
  • delayed closure of ductus is common in premature infants (1/3 of infants <1,750 g); this is different from PDA in term infants
• natural history: spontaneous closure common in premature infants, less common in term infants
• clinical presentation
  • history: asymptomatic, or have apneic or bradycardic spells, poor feeding, accessory muscle use, CHF
  • physical exam: tachycardia, bounding pulses, hyperactive precordium, wide pulse pressure, continuous “machinery” murmur best heard at left infraclavicular area
• investigations
  • ECG: may show left atrial enlargement, LVH, RVH
  • CXR: normal to mildly enlarged heart, increased pulmonary vasculature, prominent pulmonary artery
  • Echo: diagnostic
• management
  • indomethacin (Indocid®): antagonizes prostaglandin E2, which maintains ductus arteriosus patency; only effective in premature infants
  • catheter or surgical closure if PDA causes respiratory compromise, FTT, or persists beyond 3rd mo of life

2. OBSTRUCTIVE LESIONS
• present with decreased urine output, pallor, cool extremities and poor pulses, shock or sudden collapse

Coarctation of the Aorta
• definition: narrowing of aorta (almost always at the level of the ductus arteriosus)
• epidemiology: commonly associated with bicuspid aortic valve (50%); Turner syndrome (35%)
• clinical presentation
  • history: often asymptomatic
  • physical exam
    • blood pressure discrepancy between upper and lower extremities (increased suspicion/severity if >20 mmHg difference)
    • diminished or delayed femoral pulses relative to brachial (i.e. brachial-femoral delay)
    • possible systolic murmur with late peak at apex, left axilla, and left back
  if severe, presents with shock in the neonatal period when the ductus arteriosus closes
• investigations: ECG shows RVH early in infancy, LVH later in childhood; Echo or MRI for diagnosis
• prognosis: can be complicated by HTN; if associated with other lesions (e.g. PDA, VSD) can lead to CHF
• management: give prostaglandins to keep ductus arteriosus patent for stabilization and perform surgical correction in neonates; for older infants and children balloon arterioplasty may be an alternative to surgical correction. The American Heart Association and the American College of Cardiology recommend that correction of coarctation should be done as early as possible to reduce long-term morbidity and increase survival

Aortic Stenosis
• 4 types: valvular (75%), subvalvular (20%), supravalvular, and idiopathic hypertrophic subaortic stenosis (5%)
• clinical presentation
  • history: often asymptomatic, but may be associated with CHF, exertional chest pain, syncope, or sudden death
  • physical exam: SEM at RUSB with aortic ejection click at the apex (only for valvular stenosis)
• diagnosis: Echo
• management: valvular stenosis is usually treated with balloon valvuloplasty, patients with subvalvular or supravalvular stenosis require surgical repair, exercise restriction required
Pulmonary Stenosis
- 3 types: valvular (90%), subvalvular, or supravalvular
- definition of critical pulmonary stenosis: inadequate pulmonary blood flow, dependent on ductus for oxygenation, progressive hypoxia and cyanosis
- natural history: may be part of other congenital heart lesions (e.g. Tetralogy of Fallot) or in association with syndromes (e.g. congenital rubella, Noonan syndrome)
- clinical presentation
  - history: spectrum from asymptomatic to CHF
  - physical exam: wide split S2 on expiration, SEM at LSB, pulmonary ejection click (for valvular lesions)
- investigations
  - ECG: RVH
  - CXR: post-stenotic dilation of the main pulmonary artery
  - Echo: diagnostic
- management: surgical repair if critically ill or if symptomatic in older infants/children

Cyanotic Congenital Heart Disease
- systemic venous return re-enters systemic circulation directly
- most prominent feature is cyanosis (O₂ sat <75%)
- hyperoxic test differentiates between cardiac and other causes of cyanosis
  - obtain preductal, right radial ABG in room air, then repeat after the child inspires 100% O₂
  - if PaO₂ improves to greater than 150 mmHg, cyanosis less likely cardiac in origin
- pre-ductal and post-ductal pulse oximetry
  - >5% difference suggests R to L shunt

1. RIGHT-TO-LEFT SHUNT LESIONS

Tetralogy of Fallot
- epidemiology: 10% of all CHD, most common cyanotic heart defect diagnosed beyond infancy with peak incidence at 2-4 mo of age
- pathophysiology
  - embryological defect due to anterior and superior deviation of the outlet septum leading to: VSD, RVOTO (i.e. pulmonary stenosis), over-riding aorta, and RVH
  - infants may initially have a L → R shunt (therefore no cyanosis); however, RVOTO is progressive, leading to increasing R → L shunting with hypoxemia and cyanosis
  - degree of RVOTO determines the direction and degree of shunt and, therefore, the extent of clinical cyanosis and degree of RVH
- clinical presentation
  - history: hypoxic “tet” spells
    - during exertional states (crying, exercise) the increasing pulmonary vascular resistance and decrease in systemic resistance causes an increase in right-to-left shunting
    - clinical features include paroxysms of rapid and deep breathing, irritability and crying, increasing cyanosis, decreased intensity of murmur (decreased flow across RVOTO)
  - if severe, can lead to decreased level of consciousness, seizures, death
  - physical exam
    - single loud S2 due to severe pulmonary stenosis (i.e. RVOTO), SEM at LSB
- investigations
  - ECG: RAD, RVH
  - CXR: boot-shaped heart, decreased pulmonary vasculature, right aortic arch (in 20%)
  - Echo: diagnostic
  - management of spells: O₂, knee-chest position, fluid bolus, morphine sulfate, propranolol
  - treatment: surgical repair at 4-6 mo of age; earlier if marked cyanosis or “tet” spells

2. OTHER CYANOTIC CONGENITAL HEART DISEASES

Transposition of the Great Arteries (TGA)
- epidemiology: 3-5% of all congenital cardiac lesions, most common cyanotic CHD in neonates
- pathophysiology: parallel pulmonary and systemic circulations
  - systemic: body → RA → RV → aorta → body
  - pulmonary: lungs → LA → LV → pulmonary artery → lungs
  - survival is dependent on mixing through PDA, ASD, or VSD
- physical exam
  - neonates: ductus arteriosus closure causes rapidly progressive severe hypoxemia unresponsive to oxygen therapy, acidosis, and death
  - VSD present: cyanosis is not prominent; CHF within first weeks of life
  - VSD absent: no murmur

Causes of Cyanotic Heart Disease – 5T’s
- Truncus arteriosus
- Transposition of the great vessels
- Tricuspid atresia
- Tetralogy of Fallot
- Total anomalous pulmonary venous return

Ebstein’s Anomaly
- Septal and posterior leaflets of tricuspid valve are malformed and displaced into the RV
- Potential for RV dysfunction, tricuspid stenosis, tricuspid regurgitation, or functional pulmonary atresia if RV unable to open pulmonary valves
- Accessory conduction pathways (e.g. WPW) are often present

Etiology
- Unknown, associated with maternal lithium and benzodiazepine use in 1st trimester

Treatment
- Newborns: consider closure of tricuspid valve + aortopulmonary shunt, or transplantation
- Older children: tricuspid valve repair or valve replacement + ASD closure

Transposition of the great arteries

figure 5. tetralogy of fallot

figure 6. transposition of the great arteries
• investigations
  ▪ ECG: RAD, RVH, or may be normal
  ▪ CXR: egg-shaped heart with narrow mediastinum (“egg on a string”)
  ▪ Echo: diagnostic

• management
  ▪ symptomatic neonates: prostaglandin E1 infusion to keep ductus open until balloon atrial septostomy
  ▪ surgical repair: arterial switch performed in the first two weeks in those without a VSD while LV muscle is still strong

**Total Anomalous Pulmonary Venous Return**
• epidemiology: 1-2% of CHD
• pathophysiology
  ▪ all pulmonary veins drain into right-sided circulation (systemic veins, RA)
  ▪ no direct oxygenated pulmonary venous return to left atrium
  ▪ often associated with obstruction at connection sites
  ▪ ASD must be present for oxygenated blood to shunt into the LA and systemic circulation
• management: surgical repair in all cases and required urgently for severe cyanosis

**Truncus Arteriosus**
• pathophysiology
  ▪ single great vessel gives rise to the aorta, pulmonary, and coronary arteries
  ▪ truncal valve overlies a large VSD
  ▪ potential for coronary ischemia with fall in pulmonary vascular resistance
• management: surgical repair within first 6 wk of life

**Hypoplastic Left Heart Syndrome**
• epidemiology: 1-3% of CHD; most common cause of death from CHD in first month of life
• pathophysiology: LV hypoplasia may include atretic or stenotic mitral and/or aortic valve, small ascending aorta, and coarctation of the aorta with resultant systemic hyoperfusion
• systemic circulation is dependent on ductus patency; upon closure of the ductus, infant presents with circulatory shock and metabolic acidosis
• management
  ▪ intubate and correct metabolic acidosis
  ▪ IV infusion of prostaglandin E1 to keep ductus open
  ▪ surgical palliation (overall survival 50% to late childhood) or heart transplant

**Congestive Heart Failure**
• see Cardiology and Cardiac Surgery, C33

**Etiology**
• CHD
• cardiomyopathy (primary or secondary)
• high output circulatory states (e.g. anemia, AVMs, cor pulmonale, hyperthyroidism)
• non-cardiac (e.g. sepsis, renal failure)
• pressure overload (e.g. aortic stenosis/coarctation, pulmonary stenosis, HTN)
• volume overload (e.g. L to R shunt, valve insufficiency)

**History**
• infant: feeding difficulties, early fatigability, diaphoresis while sleeping or eating, respiratory distress, lethargy, FTT
• child: decreased exercise tolerance, fatigue, decreased appetite, respiratory distress, frequent URTIs or “asthma” episodes
• orthopnea, paroxysmal nocturnal dyspnea, pedal/dependent edema are all uncommon in children

**Physical Findings**
• 4 key features: tachycardia, tachypnea, cardiomegaly, hepatomegaly
• FTT
• alterations in peripheral pulses, four limb blood pressures (in some CHDs)
• dysmorphic features associated with congenital syndromes

**Investigations**
• CXR: cardiomegaly, pulmonary venous congestion
• ECG: sinus tachycardia, signs of underlying cause (heart block, atrial enlargement, hypertrophy, ischemia/infarct)
• Echo: structural and functional assessment
• blood work: CBC, electrolytes, BUN, Cr, LFTs
Management
• general: sitting up, O₂, sodium and water restriction, increased caloric intake
• pharmacologic: diuretics, afterload reduction (e.g. ACE inhibitor), β-blockers; digoxin rarely used
• curative: correction of underlying cause

Dysrhythmias

• see Cardiology and Cardiac Surgery, C15
• can be transient or permanent, congenital (structurally normal or abnormal) or acquired (toxin, infection, infarction)

Sinus Arrhythmia
• phasic variations with respiration (present in almost all normal children)

Sinus Tachycardia
• rate of impulses arising from sinus node is elevated (>150 bpm in infants, >100 bpm in older children)
• characterized by: beat-to-beat heart rate variability with changes in activity, P waves present/normal, PR constant, QRS narrow
• etiology: HTN, fever, anxiety, sepsis, anemia/hypoxia, PE, drugs, etc.
• differentiate from SVT (see below) by slowing the sinus rate (vagal massage, β-blockers) to identify sinus P waves

Premature Atrial Contractions
• may be normal variant or can be caused by electrolyte disturbances, hyperthyroidism, cardiac surgery, digitalis toxicity

Premature Ventricular Contractions
• common in adolescents
• benign if single, uniform, disappear with exercise, and no associated structural lesions
• if not benign, may degenerate into more severe dysrhythmias

Supraventricular Tachycardia
• abnormally rapid heart rhythm originating above the ventricles – most frequent sustained dysrhythmia in children
• no beat-to-beat HR variability, >220 bpm (infants) or >180 bpm (children), P waves absent/normal, PR indeterminable, QRS usually narrow
• pre-excitation syndrome (subset of SVT): WPW syndrome, congenital defect (see Cardiology and Cardiac Surgery, C21)

Complete Heart Block
• congenital heart block can be caused by maternal anti-Ro or anti-La (e.g. mother with SLE)
• often diagnosed in utero (may lead to development of fetal hydrops)
• clinical symptoms related to level of block (the lower the block, the slower the heart rate and greater the symptoms of inadequate cardiac output)
• symptomatic patients need a pacemaker

Heart Murmurs

• 50-80% of children have audible heart murmurs at some point in their childhood
• most childhood murmurs are functional (e.g. “innocent”) without associated structural abnormalities and have normal ECG and radiologic findings
• in general, murmurs can become audible or accentuated in high output states (e.g. fever, anemia)

Table 11. Differentiating Heart Murmurs

<table>

Pediatric vs. Adult ECG
Pediatric ECG findings that may be normal:
• HR >100 bpm
• Shorter PR and QT intervals and QRS duration
• Inferior and lateral small Q waves
• RV larger than LV in neonates, so normal to have:
  • RAD
  • Large precordial R waves
  • Upright T waves
  • Inverted T waves in the anterior precordial leads from early infancy to teen years

**Infecive Endocarditis**

- see *Infectious Diseases, ID17*

**Development**

- also known as Early Developmental Impairment

**Approach to Global Developmental Delay**

- Definition
  - performance significantly below average in two or more domains of development
  - when persistent, these become developmental disabilities, which are lifelong impairments

- Epidemiology
  - 5-10% of children have neurodevelopmental delay
  - careful evaluation can reveal a cause in 50-70% of cases

- Etiology
  - CNS abnormalities (meningitis/encephalitis, brain malformation, trauma, etc.)
  - sensory deficits (hearing, vision)
  - environmental (psychosocial neglect, lead exposure, antenatal drug or alcohol exposure, etc.)
  - genetic/chromosomal disorders (DS, Fragile X, etc.)
  - metabolic disorders (inborn errors of metabolism, hypothyroidism, etc.)
  - obstetrical (prematurity, HIE, TORCH infections, etc.)

- Clinical Presentation
  - history
    - intraterine exposures, perinatal events
    - detailed developmental milestones: rate of acquisition, regression of skills
    - associated problems: feeding, seizures, behavior, sleep
    - family history, consanguinity
    - social history
  - physical exam
    - dysmorphic features, hepatosplenomegaly, neurocutaneous markers, growth parameters, detailed neurological examination
  - investigations
    - neurodevelopmental assessment, vision and hearing test, psychosocial evaluation, OT, PT and/or SLP assessments, genetics consultation
    - laboratory testing and imaging (guided by history and physical exam)
    - microarray, chromosomes, FISH, Fragile X testing, neuroimaging, metabolic workup, neuroelectrophysiologic testing

- Management
  - dependent on specific area of delay
  - therapy services (e.g. speech and language therapy for language delay, OT and/or PT for motor delay), early intervention services (e.g. infant development services)
**Intellectual Disability**

**Definition**
- state of functioning that begins in childhood and is characterized by limitations in both intelligence and adaptive skills
- historically defined as an IQ <70

**Epidemiology**
- 1% of general population; M:F = 1.5:1

**Etiology**
- any disorder that interferes with brain development and functioning
- prenatal (majority): TORCH infections, FASD
- genetic/metabolic: DS, Fragile X, PKU, untreated or delayed diagnosis of congenital hypothyroidism, CNS abnormalities, other chromosomal/metabolic disorders

**Risk Factors**
- male, consanguineous parents, family history, older maternal age, decreasing maternal education, certain ethnicities
- prenatal: pre-eclampsia, maternal malnutrition or DM
- perinatal: prematurity, low birth weight, birth trauma/hypoxia
- postnatal: ICH, CNS or other serious infection, hypoxia, environmental toxins, psychosocial deprivation, malnutrition

**Clinical Presentation**
- history
  - well below average general intellectual functioning
  - significant deficits in adaptive functioning in at least two of: communication, self-care, home-living, social skills, self-direction, academic skills, work, leisure, health, safety
- physical exam
- check growth, dysmorphic features, complete physical exam
- investigations
  - standardized psychology assessment (includes IQ test and measure of adaptive functioning)
  - vision, hearing, and neurologic assessment
  - genetic and metabolic testing as indicated

**Management**
- main objective: enhance adaptive functioning level
- requires an interprofessional team with strong case co-ordination
- emphasize community-based treatment and early intervention
- individual/family therapy, behavior management services, therapy services (e.g. OT, SLP), medications for associated conditions
- education: life skills, vocational training, communication skills, family education
- psychosocial support for individual and family; respite care

**Prognosis**
- higher rates of sensory deficits, motor impairment, behavioral/emotional disorders, seizures, psychiatric illness

**Classification of Intellectual Disability**

**DSM-5 Criteria for Intellectual Disability**
- Deficits in intellectual functioning
- Deficits or impairments in adaptive functioning
- These limitations are evident during childhood or adolescence

**Language Delay**

**Definition**
- no universally accepted definition, but often identified around 18 mo of age with enhanced well baby visit
- if formally tested, performance on a standardized assessment of language is at least one standard deviation below mean of age
- can be expressive (ability to produce or use language), receptive (ability to understand language), or both

**Epidemiology**
- ~10-15% of 2 yr children have a language delay, but only 4-5% remain delayed after 3 yr
- ~6-8% of school-aged children have specific language impairment (many of whom were not identified before school entry)
**Etiology**
- cognitive disability
- constitutional language delay
- genetic/metabolic: DS, Fragile X syndrome, Williams syndrome, hypothyroidism, PKU, etc.
- hearing impairment
- mechanical problems: cleft palate, cranial nerve palsy
- medical condition: seizure disorder (includes acquired epileptic aphasia), CP, TORCH infection, iron deficiency, lead poisoning, etc.
- autism spectrum disorder
- psychosocial: neglect or abuse
- selective mutism

**Risk Factors**
- male, positive family history, prematurity, psychosocial (poverty, low parental education, maternal depression)

**Clinical Presentation**
- history
  - concerns about hearing, delay in language development or regression in previously normal language development
  - delayed language milestones on well-child check up; presence of red flags
  - must determine if language delay is expressive, receptive, or mixed
  - children with expressive language delays may have concurrent behavior problems or drooling (because of abnormal oral musculature)
  - risk factors for hearing loss (hereditary, recurrent AOM) and language delay
- physical exam
  - guided by history: look for abnormal growth, dysmorphisms, unusual social interactions (lack of eye contact, not pointing)
  - include full exam of the external/internal ear (e.g. TM scarring), oral pharynx (e.g. cleft palate), and neurologic system (including tone)
- investigations
  - use of language specific screens in primary care setting: The Early Language Milestone, CAT/CLAMS, MCHAT, etc.
  - all children with suspected language delay MUST be referred to an audiologist for a hearing assessment
  - CBC (to rule out anemia), venous blood lead levels, genetic/metabolic workup as indicated

**Management**
- specific to etiology
- often multidisciplinary and requires appropriate referrals: early intervention services, special education services, SLP, OHNS and dental professionals, general support services
- primary care provider can help reinforce family’s understanding of delay and provide follow-up and care coordination
- prevention: parents can read aloud to their child, engage in dialogic reading, avoid baby talk, narrate daily activities, etc.

**Prognosis**
- depends on etiology
- if language delay persists beyond 5 yr old, more likely to have difficulties in adulthood
- persistent language delay is associated with poor academic performance, behavioral problems, social isolation

---

**Fetal Alcohol Spectrum Disorder**

**Definition**
- term describing the range of effects of prenatal exposure to alcohol, including physical, mental, behavioral, and learning disabilities
- no “safe” level of alcohol consumption during pregnancy has been established
- spectrum includes: FAS, partial FAS, ARBD, and ARND

**Epidemiology**
- prevalence of FAS and FASD is 0.1% and 1.0%, respectively
- most common preventable cause of intellectual disability

**Pathogenesis**
- specific mechanism of FASD is unknown, but hypotheses include nutritional deficits, toxic effects of acetaldehyde, alteration of placental transport, abnormal protein synthesis, and altered cerebral neurotransmission
Diagnosis
- often misdiagnosed or missed entirely
- diagnosis of FAS, ARBD, and ARND all require evidence of maternal drinking during pregnancy
- criteria for diagnosis of FAS
  - agrowth deficiency: low birth weight and/or decelerating weight over time not due to nutrition
  - characteristic pattern of facial anomalies: short palpebral fissures, flattened philtrum, thin upper lip, flat midface
  - CNS dysfunction: microcephaly and/or neurobehavioral dysfunction (hyperactivity, fine motor problems, attention deficits, learning disabilities, cognitive disabilities, difficulties in adaptive functioning, etc.)
- criteria for diagnosis of ARBD
  - congenital anomalies, including malformations and dysplasias of the cardiac, skeletal, renal, ocular, and auditory systems
- criteria for diagnosis of ARND
  - CNS dysfunction (similar to FAS)
  - complex pattern of behavioral or cognitive abnormalities inconsistent with developmental level that cannot be explained by familial background or environment alone

Management
- early diagnosis is essential to prevent secondary disabilities
- no cure, but individuals with FASD and their families should be linked to community resources and services to improve outcome

Prognosis
- secondary disabilities include unemployment, mental health problems, difficulties with the law, inappropriate sexual behavior, disrupted school experience, peer problems

Learning Disabilities

Definition
- specific and persistent failure to acquire academic skills despite conventional instruction, adequate intelligence, and sociocultural opportunity
- a significant discrepancy between a child's intellectual ability and their academic performance
- several types: learning disabilities in reading, writing, mathematics

Epidemiology
- prevalence: 2-10%
- high incidence of psychiatric comorbidity: anxiety, dysthymia, conduct disorder, major depressive disorder, oppositional defiant disorder, ADHD

Etiology
- pathogenesis is unknown, likely genetic factors involved
- learning disabilities may be associated with a number of conditions:
  - genetic/metabolic: Turner syndrome, Klinefelter syndrome
  - perinatal: prematurity, low birth weight, birth trauma/hypoxia
  - postnatal: CNS damage, hypoxia, environmental toxins, FAS, psychosocial deprivation (understimulation), malnutrition
- poor visual acuity is NOT a cause

Risk Factors
- positive family history, prematurity, other developmental and mental health conditions, neurologic disorders (e.g. seizure disorders, neurofibromatosis), history of CNS infection/irradiation/traumatic injury

Clinical Presentation
- history and physical exam
  - school difficulties (academic achievement, behavior, attention, social interaction)
  - development of negative self-concept → reluctance to participate even in areas of strength
  - social issues: overt hostility towards parents/teachers; difficulties making friends for several reasons (problems remembering names, difficulties with language to engage in conversations, inability to understand games and complex rules, etc.), bullying, and anxiety
  - look for dysmorphisms, complete physical exam
- investigations
  - standardized tests for IQ
  - individual scores on achievement tests in reading, mathematics, or written expression (WISC III, WRAT) >2 SD below that expected for age, education, and IQ
Management
• provide quality instruction for specific learning disability
• support student by modifying the curriculum and/or providing accommodations (e.g. scribe for writing, extra time for tests, photocopied notes, etc.)
• consider grade retention in certain students
• specialized education placements that can provide educational remediation

Prognosis
• limited information available about persistence of learning disabilities over time
• low self-esteem, poor social skills, 40% school drop-out rate

Motor Delay
• see Cerebral Palsy, P87 and Muscular Dystrophy, P45

Endocrinology

Antidiuretic Hormone

Diabetes Insipidus
• see Endocrinology, E19 and Nephrology, NP11

Syndrome of Inappropriate Antidiuretic Hormone
• see Endocrinology, E19 and Nephrology, NP9

Diabetes Mellitus

DIABETES MELLITUS TYPE 1
• insulin deficiency following destruction of the pancreatic β cells

Epidemiology
• most common form of DM in children, M=F
• variable prevalence internationally, affects ~1.7:1,000 children and adolescents in the US
• can present at any age, but bimodal peaks at 5-7 yr old and at puberty

Etiology
• type 1A: cell-mediated autoimmune destruction of β-cells of the pancreas
• type 1B: rare, non-immune variation; unknown cause
• disease results from some level of genetic predisposition and an environmental trigger
  ▪ human leukocyte antigen locus confers ~50% of genetic susceptibility
  ▪ trigger likely infectious and/or hormonal (as suggested by bimodal peaks in age of onset)

Risk Factors
• positive family history of type 1 DM, personal or family history of other autoimmune diseases

Clinical Presentation
• history
  ▪ initially presents as polyuria, often manifested as nocturia or secondary enuresis
  ▪ polydipsia, weight loss (lack of insulin leading to a catabolic state), and polyphagia
  ▪ DKA on initial presentation (~20%); vomiting, abdominal pain, confusion/lethargy
• physical exam
  ▪ tachypnea, signs of dehydration, ↓ LOC, Kussmaul's respiration, ketone breath
• investigations
  ▪ initial tests: urine dipstick (glucose, ketones), random blood glucose (200 mg/dL)
  ▪ DKA blood work: venous/arterial blood gas, osmolarity, plasma glucose, bicarbonate, HbA1c, serum ketones, BUN, Cr, electrolytes, CBC
  ▪ if etiology is unclear, consider ordering autoimmune antibodies (anti-Gad, anti-islet)

Management
• disclose diagnosis and prompt patient education around survival skills, meal plans, and insulin injections
• refer patient to diabetes team with pediatric expertise for education, ongoing care, and psychosocial support
• management is multidisciplinary and family-centered
• conventional insulin regimen
  ▪ 2/3 of total daily insulin dose in AM (1/3 rapid acting + 2/3 intermediate-acting)
  ▪ 1/3 of total daily insulin dose in PM (1/3 rapid acting + 2/3 intermediate-acting)

Diagnostic Criteria for DM (Types 1 and 2)
One of:
• HbA1c ≥ 6.5% (not validated in children)
• Fasting glucose ≥ 126 mg/dL
• 2 h plasma glucose during OGTT ≥ 200 mg/dL
• Random glucose ≥ 200 mg/dL with classic symptoms of hyperglycemia (polyuria, polydipsia, weight loss)

Blood Glucose Targets by Age

<table>
<thead>
<tr>
<th>Age</th>
<th>Pre-Meal Blood Glucose Target</th>
<th>HbA1c Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;6</td>
<td>100-180 mg/dL</td>
<td>&lt;8.5%</td>
</tr>
<tr>
<td>6-12</td>
<td>90-180 mg/dL</td>
<td>&lt;8%</td>
</tr>
<tr>
<td>13-19</td>
<td>90-150 mg/dL</td>
<td>&lt;7.5%</td>
</tr>
<tr>
<td>&gt;19</td>
<td>As adult</td>
<td>&lt;7%</td>
</tr>
</tbody>
</table>
• intensive insulin regimen (multiple daily injections)
  ▪ studies show increased glycemic control with intensive vs. conventional dosing
  ▪ 1/2 of total daily insulin dose as long-acting insulin (either morning or bedtime)
  ▪ remainder of total daily insulin dose given as short or rapid-acting insulin divided before meals (dosage varies between meals depending on glucose content of meal and exercise/activity pattern)
  ▪ can also use insulin infusion pump
• blood glucose monitoring
  ▪ tight glycemic control decreases rate of long-term complications
  ▪ glycemic targets: age <6 fasting blood glucose (BG)100-180 mg/dL, HbA1c ≤ 8%; age 6-12 fasting BG 90-180 mg/dL, HbA1c ≤ 8%; age 13-19 fasting BG 90-150 mg/dL, HbA1c ≤ 7.5%
• for tighter control, may consider continuous subcutaneous insulin infusion (CSII) pump or MDI (multiple daily injections regimen: basal insulin plus analog for meals)
• young children are more susceptible to hypoglycemia
• if DKA present: ABCs, admit, monitors, correct fluid losses, administer insulin and restore glucose gradually, correct electrolyte disturbances, identify/treat precipitating event, avoid complications (i.e. cerebral edema)
• low threshold to investigate (CT/MRI) and treat DKA, as cerebral edema is a major concern
• screen for micro- and macrovascular complications (regular ophthalmology assessments, blood pressure, microalbuminuria), concurrent autoimmune diseases (thyroiditis, celiac disease, etc.), and mental health issues (depression, eating disorders)

**Prognosis**
• no cure currently
• short-term complications
  ▪ hypoglycemia
    ▪ due to missed/delayed meals, excess insulin or exercise, illness
  ▪ can lead to seizures and/or coma
  ▪ reversed with PO/IV glucose or IM glucagon
  ▪ hyperglycemia
    ▪ due to intercurrent illness, diet-to-insulin mismatch
    ▪ ↑ risk of end-organ damage
  ▪ DKA: due to missed insulin doses, infection; most common cause of death
• long-term complications
  ▪ microvascular: retinopathy, nephropathy, neuropathy
  ▪ macrovascular: metabolic syndrome, CVD, CAD, PVD
  ▪ increased risk of other autoimmune diseases

**DIABETES MELLITUS TYPE 2**
• see Family Medicine, FM22, Endocrinology, E6
• impaired glucose metabolism due to increased peripheral insulin resistance
• rare before 10 yr of age, but more common in older children/adolescents
• prevalence is rising mainly due to the increased incidence of childhood obesity
• risk factors: obesity, positive family history, female gender, certain ethnic groups
• clinical presentation may be similar to that of type 1 DM, though most children are asymptomatic
• may present in DKA or hyperglycemic hyperosmotic nonketotic state
• management
  ▪ criteria to start insulin: distinction between type 1 and type 2 DM unclear, child is ketotic or in ketoacidosis, random blood glucose ≥250 mg/dL, or HbA1c >9%
  ▪ initiate lifestyle modification program, including diet, weight loss, physical activity (moderate-to-vigorous activity for at least 60 min/d; screen time less than 2 h/d)
  ▪ start metformin as 1st line therapy at time of diagnosis
  ▪ glycemic target: HbA1c ≤ 7%
  ▪ if glycemic targets not achieved within 3-6 mo from diagnosis with lifestyle intervention alone, either metformin, glimepiride, or insulin should be initiated
  ▪ monitor HbA1c every 3 mo
  ▪ advise patient to monitor finger-stick blood glucose levels if on medication with risk of hypoglycemia, are changing medication regimen, have not met treatment goals, or have intercurrent illness
• prognosis: includes microvascular and macrovascular complications similar to type 1 DM

**Growth**

**APPROACH TO SHORT STATURE**

**Definition**
• short stature: height <3rd percentile
• poor growth evidenced by growth deceleration (height crosses major percentile lines, growth velocity <25th percentile)
Epidemiology
• ~2.5% of the population by definition

Etiology
• see sidebar

Clinical Presentation
• history and physical exam
  ▪ plot on growth curve (special growth charts available for Turner syndrome, achondroplasia, DS)
  ▪ assess for dysmorphic features, disproportionate short stature
  ▪ risk factors for GH deficiency: previous head trauma, history of intracranial bleed or infection, head surgery or irradiation, positive family history, breech delivery
  ▪ decreased growth velocity may be more worrisome than actual height
• investigations
  ▪ calculate mid-parental height: children are usually in a percentile between their parents’ height
  ▪ AP x-ray of left hand and wrist for bone age
  ▪ remaining investigations guided by history and physical (e.g. TSH, sweat chloride, etc.)

Management
• depends on severity of problem as perceived by parents/child
• no treatment for non-pathological short stature, except for idiopathic short stature
• GH therapy: if administered at an early age, can help patients achieve adult height
• requirements
  ▪ GH shown to be deficient by 2 different stimulation tests
  ▪ growth velocity <3rd percentile or height <3rd percentile
  ▪ bone age x-rays show unfused epiphyses/delayed bone age
• support and management of resultant self-image issues, social anxiety, etc.

TALL STATURE
• height greater than two SD above the mean for a given age, sex, and race

Etiology
• constitutional/familial
• endocrine: Beckwith-Wiedemann syndrome, hyperthyroidism, hypophyseal gigantism, precocious puberty
• genetic: homocystinuria, Klinefelter syndrome, Marfan syndrome, Sotos syndrome
Hypercalcemia/Hypocalcemia/Rickets

- see [Endocrinology, E39, E40, E45]

Hyperthyroidism and Hypothyroidism

- may be congenital or acquired (for acquired causes, see [Endocrinology, E20 and E26])

CONGENITAL HYPERTHYROIDISM

- also known as neonatal Graves' disease

Epidemiology

- ~1:25,000 neonates, M=F

Etiology

- results from transplacental passage of maternal thyroid stimulating antibodies from mother with a history of Graves' disease

Clinical Presentation

- history and physical exam
  - clinical manifestations may be masked if mother on antithyroid treatment
  - may present with tachycardia with CHF, heart murmur, goiter, craniosynostosis, irritability, poor feeding, FTT
- investigations
  - serum levels of TSH and free T4 in all infants with suspected congenital hyperthyroidism, or infants born to mothers with Graves' disease

Management

- methimazole until antibodies cleared
- symptomatic treatment as needed (e.g. β-blockers to control tachycardia)

Prognosis

- if prompt and adequate treatment given, most neonates improve rapidly
- antibodies usually spontaneously cleared by 2-3 mo of life
- fetal or neonatal hyperthyroidism may have adverse effects on CNS development, leading to developmental and behavior problems

CONGENITAL HYPOTHYROIDISM

Epidemiology

- incidence: 1:4,000-1:20,000 newborn births; F:M = 2:1
- one of the most common preventable causes of intellectual disability

Etiology

- may be classified as permanent primary, central, or transient hypothyroidism
- ~85% of primary cases are sporadic (mostly thyroid dysgenesis), remaining 15% are hereditary (mostly inborn errors of thyroid synthesis)
- causes of transient hypothyroidism: maternal antibody-mediated, iodine deficiency (rare in developed countries), prenatal exposure to antithyroid medications

Clinical Presentation

- history and physical exam
  - usually asymptomatic in neonatal period because maternal T4 crosses the placenta
  - prolonged jaundice, constipation, sluggish, hoarse cry, lethargy, poor feeding, macroglossia, coarse facial features, large fontanelles, umbilical hernia
- investigations
  - diagnosis through newborn screening of TSH or free T4; abnormal results should be confirmed with serum levels from venipuncture

Management

- thyroxine replacement
Prognosis
• excellent outcome if treatment started within 1-2 mo of birth
• if treatment started after 3-6 mo of age, may result in permanent developmental delay and/or
  disability (mild to profound)

Sexual Development

AMBIGUOUS GENITALIA

Definition
• newborn or child whose gender is difficult to assign based on the appearance of genitalia
• subtype of DSD: a condition in which development of chromosomal, gonadal, or anatomic sex is
  atypical
• subtypes: 46,XX DSD, 46,XY DSD, ovotesticular DSD (true hermaphrodite)

Epidemiology
• incidence of genital abnormalities at birth is as high as 1:300
• prevalence of complex anomalies with true sexual ambiguity much lower at ~1:5,000

Etiology
• 46,XY DSD
  ▪ inborn error of testosterone biosynthesis or Leydig cell hypoplasia
  ▪ 5-α-reductase deficiency, androgen receptor deficiency, or insensitivity
  ▪ LH/hCG unresponsiveness
• 46,XX DSD
  ▪ virilizing CAH (most common)
  ▪ maternal source: virilizing ovarian or adrenal tumors, untreated maternal CAH, placental
    aromatase deficiency
  ▪ ovotesticular DSD
    ▪ both ovarian follicles and seminiferous tubules in the same patient with a 46,XX karyotype
    ▪ mixed gonadal dysgenesis

Risk Factors
• parental consanguinity, positive family history of ambiguous genitalia, early childhood illness/
  death, or primary amenorrhea, maternal medications during pregnancy (e.g. androgens,
  progesterones, danazol, phenytoin, aminoglutethimide, endocrine disruptors)

Clinical Presentation
• history
  ▪ thorough obstetrical history, including prenatal screens and maternal medications
  ▪ family history: autosomal recessive pattern may suggest CAH, X-linked recessive pattern
    may suggest androgen insensitivity syndrome
• physical exam
  ▪ male pseudohermaphrodite (XY): small phallus, hypospadias, undescended testicles
  ▪ female pseudohermaphrodite (XX): clitoral hypertrophy, labioscrotal fusion
  ▪ look for concurrent midline defects, dysmorphic features, and congenital abnormalities
• investigations
  ▪ karyotype and genetic workup as indicated
  ▪ blood work: electrolytes and renin (evidence of salt-wasting in CAH); 17-OH-progesterone,
    androgens, FSH, and LH
  ▪ imaging: abdominal U/S to look for uterus, testicles, ovaries

Management
• depends on underlying etiology
• avoid announcement of probable sex or use of personal pronouns until all tests are complete
• continuous psychosocial support for parents and child during development
• elective surgical reconstruction of genitalia is sometimes possible

CONGENITAL ADRENAL HYPERPLASIA

Definition
• autosomal recessive disorder characterized by the partial or total defect of various synthetic
  enzymes of the adrenal cortex required for cortisol and aldosterone production
Epidemiology
- occurs in ~1:15,000 live births
- most common cause of ambiguous genitalia

Etiology
- for biosynthetic pathways of adrenal cortex, see Endocrinology E29
- 21-OH responsible for ~95% of CAH cases
- results in ↓ cortisol and aldosterone production with shunting toward ↑ androgens
- cortisol deficiency leads to elevated ACTH, which causes adrenal hyperplasia
- rarer causes include deficiencies in 11-OH, cholesterol desmolase, 17-OH, and 3-HSD

Clinical Presentation
- depends on which enzyme in cortisol synthesis pathway is defective
- presentation of 21-OH deficiency can be divided into
  - classic deficiency with salt wasting: inadequate aldosterone resulting in FTT, hyperkalemia, hyponatremia, hypoglycemia, acidosis
  - classic deficiency without salt wasting: simple virilizing type
  - non-classic: signs/symptoms of androgen excess (e.g. amenorrhea, precocious puberty, etc.)
- 21-OH deficiency screening is part of many newborn screening programs across North America
- high serum levels of 17-OH progesterone in random blood sample diagnostic for 21-OH deficiency

Management
- correct any abnormalities in fluids, electrolytes, or serum glucose
- provide glucocorticoids/mineralocorticoids as necessary, extra glucocorticoids in times of stress
- psychosocial support

Prognosis
- complications if untreated include virilization, acne, salt wasting, hypotension

NORMAL PUBERTAL DEVELOPMENT

Physiology
- puberty occurs with the maturation of the HPG axis
- ↑ pulsatile release of GnRH → ↑ release of LH and FSH → maturation of gonads, release of sex steroids → secondary sexual characteristics
- adrenal production of androgens also required

Females
- onset: age 8-13 yr old (may start as early as 7 yr in girls of African descent)
- usual sequence
  1. thelarche: breast budding
  2. pubarche: axillary hair, body odor, mild acne
  3. growth spurt
  4. menarche: mean age 12.5 yr; indicates that growth spurt is almost complete; menses may be irregular in duration and length of cycle
- early puberty is common and often constitutional, late puberty is rare (rule out organic causes)

Males
- onset: age 9-14 yr old
- usual sequence
  1. testicular enlargement
  2. penile enlargement
  3. pubarche: axillary and facial hair, body odor, mild acne
  4. growth spurt: occurs later in boys
- early puberty is uncommon (rule out organic causes), late puberty is common and often constitutional
- gynecomastia (transient development of breast tissue) is a common self-limited condition seen in 50% of males during puberty (but any discharge from nipple or fixed mass should be investigated)

Tanner Staging
- scale used in pediatrics that defines physical measurements of development based on external primary and secondary sex characteristics
PRECOCIOUS PUBERTY

Definition
- development of secondary sexual characteristics 2-2.5 SD before population mean
- <8 yr old for females, <9 yr old for males

Epidemiology
- F>M = 1/10,000

Etiology
- usually idiopathic in females (90%), more suggestive of pathology in males (50%)
- central (GnRH dependent)
  - hypergonadotropic hypergonadism; hormone levels as in normal puberty
  - premature activation of the HPG axis
  - differential diagnosis: idiopathic or constitutional (most common in females), CNS disturbances (tumors, hamartomas, post-meningitis, increased ICP, radiotherapy), NF, primary severe hypothyroidism
- peripheral (GnRH independent)
  - hypogonadotropic hypergonadism
  - differential diagnosis: adrenal disorders (CAH, adrenal neoplasm), testicular/ovarian tumor, gonadotropin/hCG secreting tumor (hepatoblastoma, intracranial teratoma, germinoma), exogenous steroid administration, McCune-Albright syndrome, aromatase excess syndrome, rarely hypothyroidism (Van Wyk-Grumbach syndrome)

Clinical Presentation
- history
  - symptoms of puberty, family history of precocious puberty, medical illness
- physical exam
  - growth velocity
    - prepubertal: 4-6 cm/yr
    - growth spurt: boys 8-10 cm/yr, girls 6-8 cm/yr
  - complete physical exam, including Tanner staging and neurological assessment
- investigations
  - initial screening tests: bone age, serum hormone levels (estradiol, testosterone, LH, FSH, TSH, free T4, DHEA-S, 17-OH-progesterone)
  - secondary tests: MRI head, pelvic U/S, β-hCG, GnRH, and/or ACTH stimulation test

Figure 8. Tanner staging

FEMALE BREAST
- Stage 1: Papilla elevation only
- Stage 2: Breast and papilla elevated as small mound, enlargement of areola
- Stage 3: Enlargement of breast and areola, no contour separation
- Stage 4: Areola and papilla form secondary mound, no secondary mound
- Stage 5: Mature, nipple projects, no secondary mound

FEMALE GENITAL
- Stage 1: No hair, prepubertal
- Stage 2: Small amount of long, straight or curled, slightly pigmented hair along labia majora
- Stage 3: Darker, coarser, curlier hair distributed sparsely over pubes, reddening of scrotal skin
- Stage 4: Adult-type hair, no extension to medial thighs
- Stage 5: Mature distribution with spread to medial thighs

MALE GENITAL
- Stage 1: No hair, prepubertal
- Stage 2: Small amount of long, straight or curled, slightly pigmented hair along base of penis, Enlargement of testes and scrotum, reddening of scrotal skin
- Stage 3: Darker, coarser, curlier hair distributed sparsely over pubes, further enlargement of testes and scrotum
- Stage 4: Adult-type hair, no extension to medial thighs, Increase in penile circumference and length, development of glands, further enlargement of testes and scrotum, darkening of scrotal skin
- Stage 5: Mature distribution with spread to medial thighs. Adult size

A child with proven central precocious puberty should receive an MRI of the brain
Management
- indications for medical intervention to delay progression of puberty: rapid advancement of puberty, early age, risk of compromise of final adult height, psychological
- central causes: goals are to preserve height and alleviate psychosocial stress; GnRH agonists (e.g. leuprolide) most effective
- peripheral causes: goal is to limit effects of elevated sex steroids; treat underlying cause; medications that decrease the production of a specific sex steroid or block its effects (e.g. ketoconazole, spironolactone, tamoxifen, anastrozole), surgical intervention

DELAYED PUBERTY

Definition
- failure to develop secondary sex characteristics by 2-2.5 SD beyond the population mean
  - for males: lack of testicular enlargement by 14 yr old
  - for females: lack of breast development by 13 yr old OR absence of menarche by 16 yr old or within 5 yr of pubertal onset

Epidemiology
- M>F

Etiology
- usually constitutional delay in males, more suggestive of pathology in females
- central causes
  - constitutional delay in activation of HPG axis (most common)
  - hypogonadotropic hypogonadism
- peripheral causes
  - hypergonadotropic hypogonadism (e.g. primary gonadal failure, gonadal damage, Turner syndrome, hormone deficiency, androgen insensitivity syndrome, etc.)

Clinical Presentation
- history: weight loss, short stature, family history of puberty onset, medical illness, high performance athletes (females)
- physical exam: growth velocity (minimum 4 cm/yr), Tanner staging, neurological exam, complete physical exam
- investigations
  - initial screening tests: bone age, serum hormone levels (estradiol, testosterone, LH, FSH, TSH, free T4, IGF-1), CBC, electrolytes, BUN, Cr, LFTs, liver enzymes, ESR, CRP, urinalysis
  - secondary tests: MRI head, pelvic U/S, karyotype, IBD panel, celiac disease panel, LH levels following GnRH agonist

Management
- identify and treat underlying cause
- hormonal replacement: cyclic estradiol and progesterone for females, testosterone for males

Gastroenterology

Vomiting

History
- characteristic of emesis (e.g. projectile, bilious, bloody)
- pattern of emesis (e.g. association with feeds, cyclic, morning)
- red flags: bilious or bloody emesis, projectile vomit, abdominal distension and tenderness, high fever, signs of dehydration
- note that vomiting without diarrhea is most likely not gastroenteritis

Physical Findings
- vital signs to determine clinical status and hydration state

Investigations
- CBC, electrolytes, BUN, Cr, amylase, lipase, glucose done routinely
- in sick child, add: ESR, venous blood gases, C&S (blood, stool), imaging

</tbody>
</table>

**Management**
- rehydration (see Fluids and Electrolytes, P78)
- treat underlying cause

### Gastroesophageal Reflux

#### Epidemiology
- extremely common in infancy (up to 50%)

#### Clinical Presentation
- vomiting typically soon after feeding, non-bilious, rarely contains blood, small volume (<30 mL)

#### Investigations
- thriving baby requires no investigation
- investigations required if concomitant FTT, feeding aversion, recurrent cough, pneumonia or bronchospasm, GI blood loss or symptoms persist after 18 mo
Management
• conservative: thickened feeds, frequent and smaller feeds
• medical
  ▪ short-term parenteral feeding to enhance weight gain
  ▪ ranitidine, PPI: decreases gastric acidity, decreases esophageal irritation
  ▪ domperidone, metoclopramide: improves gastric emptying and GI motility; safety concerns and limited efficacy, should be reserved for children with gastroparesis contributing to GERD
• surgical: indicated for failure of medical therapy (Nissen fundoplication)

Complications
• esophagitis, strictures, Barrett’s esophagus, FTT, aspiration, oral feeding aversion

Tracheoesophageal Fistula
• see General Surgery, GS64

Pyloric Stenosis
• see General Surgery, GS61

Duodenal Atresia
• see General Surgery, GS63

Malrotation of the Intestine
• see General Surgery, GS62

Diarrhea
• definition of diarrhea varies with diet and age (stool normalcy difficult to define in children)
  • infants → increase in stool frequency to twice as often per day; older children → 3+ loose or watery stools/d
  • duration: acute: <2 wk; chronic: >2 wk

Pathophysiology
• osmotic: due to non-absorbable solutes in GI tract (e.g. lactose intolerance)
• secretory: increased secretion of Cl– ions and water in intestinal lumen (e.g. bacterial toxin)
• malabsorption: decreased GI surface area (e.g. short bowel syndrome)

History
• frequency, duration, quality of diarrhea
• associated symptoms (e.g. fever, abdominal pain, hematochezia, etc.)
• recent antibiotic use or recent travel
• elements of diet

Physical Findings
• vital signs to determine clinical status and hydration state

Investigations
• acute diarrhea
  ▪ stool for C&S, O&P, electron microscopy for viruses, C. difficile toxin, microscopy (leukocytes suggestive of invading pathogen), blood and urine cultures, blood work
• chronic diarrhea
  ▪ serial heights, weights, growth percentiles
  ▪ if child growing well and thriving, workup is limited (stool cultures as above, stool reducing substances)
  ▪ red flags: poor growth, chronic rash, other serious infections, hospitalizations for dehydration
  ▪ require full workup (as per below)
  ▪ stool: consistency, pH, reducing substances, microscopy, occult blood, O&P, C&S, C. difficile toxin, 3 d fecal fat, α-1-antitrypsin clearance, fecal elastase
  ▪ urinalysis, urine culture
  ▪ CBC, differential, ESR/CRP, smear, electrolytes, total protein, albumin, carotene, Ca²⁺, PO₄³⁻, Mg²⁺, Fe, ferritin, folate, fat-soluble vitamins, PTT, INR

Diarrhea Red Flags
Bloody stool, fever, petechiae or purpura, signs of severe dehydration, weight loss/FTT

Diarrhea is defined as an increase in frequency and/or decreased consistency of stools compared to normal

Normal stool volume:
Infants: 5-10 g/kg/d
Children: 200 g/d

Indications for Medical Evaluation of Acute Diarrhea
• Age < 6 mo
• Fever
• Visible blood in stool
• Frequent, substantial volume of diarrhea
• Signs of dehydration
• Change in mental status

MMWR Recomm Rep 2003;52(RR-16):1-16
- sweat chloride, celiac screen, thyroid function tests, urine VMA and HVA, HIV test, lead levels
- CXR, upper GI series and follow-through
- specialized tests: endoscopy, small bowel biopsy

**Gastroenteritis**

**History**
- non-specific: diarrhea, vomiting, fever, anorexia, headache, myalgias, abdominal cramps
- bacterial and parasitic agents more common in older children (2–4 yr)
- recent infectious contacts: symptoms usually begin 24–48 h after exposure

**Physical Exam**
- febrile
- dehydrated: must assess extent (see Dehydration, P78)

**Investigations**
- not usually necessary in young children
- stool analysis: leukocytes/erythrocytes suggests bacterial or parasitic etiology; pH <6 and presence of reducing substances suggests viral etiology

**Complications**
- viral gastroenteritis usually self-limiting (lasts 3–7 d in most cases)
- adverse effects related to hypovolemia, shock, tissue acidosis, and rapid onset and over-correction of electrolyte imbalances
- death in severe dehydration (rare in developed countries)

Toddler’s Diarrhea

Epidemiology
• most common cause of chronic diarrhea during infancy
• onset between 6-36 mo of age, ceases spontaneously between 2-4 yr

Clinical Presentation
• diagnosis of exclusion in thriving child
• 4-6 bowel movements per day
• diet history (e.g. excess juice intake overwhelms small bowel resulting in disaccharide malabsorption)
• stool may contain undigested food particles
• excoriated diaper rash

Management
• reassurance that it is self-limiting
• 4Fs (adequate Fiber, normal Fluid intake, 35-40% Fat, discourage excess Fruit juice)

Lactase Deficiency (Lactose Intolerance)

Clinical Presentation
• chronic, watery diarrhea and abdominal pain, bloating associated with dairy intake
• primary lactose intolerance: crampy abdominal pain with loose stool (older children, usually of East Asian and African descent)
• secondary lactose intolerance: older infant, persistent diarrhea (post viral/bacterial infection, celiac disease, or IBD)

Diagnosis
• trial of lactose-free diet
• watery stool, acid pH, positive reducing sugars
• positive breath hydrogen test if >6 yr

Management
• lactose-free diet, soy formula
• lactase-containing tablets/capsules/drops (e.g. Lacteeze®, Lactaid®)

Irritable Bowel Syndrome

• see Gastroenterology, G23

Celiac Disease

• see Gastroenterology, G18
• in children: presents at any age, usually 6-24 mo with the introduction of gluten in the diet
• FTT with poor appetite, irritability, apathy, rickets, wasted muscles, flat buttocks, rarely distended abdomen
• GI symptoms: anorexia, N/V, edema, anemia, abdominal pain
• non-GI manifestations: iron-deficiency anemia, dermatitis herpetiformis, dental enamel hypoplasia, osteopenia/osteoporosis, short stature, delayed puberty, behavioral changes
• associated with other autoimmune disorders

Milk Protein Allergy

Pathophysiology
• immune-mediated mucosal injury (IgE- and non-IgE-mediated)

Clinical Presentation
• up to 30% of children intolerant to cow’s milk may be intolerant to soy protein as well
• often history of atopy
• can present as
  • proctocolitis: mild diarrhea, small amounts of bloody stools (common presentation in young infant)
  • enterocolitis: vomiting, diarrhea, anemia, hematochezia
  • enteropathy: chronic diarrhea, hypoalbuminemia

A Celiac disease diet must avoid gluten present in "BROW" foods
- Barley
- Rye
- Oats (controversial)
- Wheat

Celiac disease is associated with an increased prevalence of IgA deficiency.
Since tTG is an IgA-detecting test, you must order an accompanying IgA level
Management
- casein hydrolysate formula (dairy-free e.g. Nutramigen®, Pregestimil®) or mother may remove all milk protein from diet and continue breastfeeding (with adequate calcium and vit D intake)
- often outgrow by 1 yr of age

Inflammatory Bowel Disease
- see Gastroenterology, G19

Cystic Fibrosis
- see Respirology, P92

Constipation
- decreased stool frequency (<3 stools/wk) and/or stool fluidity (hard, pellet-like)

FUNCTIONAL CONSTIPATION
- 99% of cases of constipation
- Rome III criteria; ≥2 of the following
  - ≤2 defecations in the toilet/wk
  - ≥1 episode of fecal incontinence/wk
  - history of retentive posturing or excessive volitional stool retention
  - history of painful or hard bowel movements
  - large fecal mass in rectum
  - history of large diameter stools that may obstruct toilet

Pathophysiology
- lack of fiber in diet or change in diet, poor fluid intake, behavioral
  - infants: often occurs when introducing cow's milk after breast milk due to high fat and solute content, lower water content
  - toddlers/older children: can occur during toilet training, or due to pain on defecation, leading to withholding of stool
  - two crucial time periods: toilet training and starting school

Management
- education: explanation of mechanism of functional constipation for parents/older children
- clean out: oral (PEG, mineral oil, or other oral laxatives) or rectal (phosphate soda, saline, or mineral oil enemas), or combination
- maintenance: adequate fluid intake (if <6 mo, 150 mL/kg/d), adequate dietary fiber (fruit, vegetables, whole grains), stool softening (PEG 3350, mineral oil), appropriate toilet training technique (dedicated time for defecation: 3-10 min, 1-2 x/d)
- children should be treated for at least 6 mo, and should not be weaned from maintenance therapy until they are having regular bowel movements without difficulty
- regular follow-up with ongoing support and encouragement is essential

Complications
- pain retention cycle: anal fissures + pain → withhold passing stool → chronic dilatation ± overflow incontinence

HIRCHSPRUNG’S DISEASE (Congenital Aganglionic Megacolon)
- see General Surgery, GS63

OTHER ORGANIC DISORDERS CAUSING CONSTIPATION
- endocrine: hypothyroidism, DM, hypercalcemia
- neurologic: spinal cord abnormalities/truma, NF
- anatomic: bowel obstruction, anus (imperfurate, atresia, stenosis, anteriorly displaced)
- drugs: lead, chemotherapy, opioids
- others
Abdominal Pain

ACUTE ABDOMINAL PAIN

History
- description of pain (location, radiation, duration, constant vs. colicky, relation to meals)
- associated symptoms: N/V, diarrhea, fever

Physical Exam
- abdominal exam, peritoneal signs, bowel sounds, rectal exam, rash

Investigations
- CBC, differential, urinalysis to rule out UTI

Table 16. Differential Diagnosis of Acute Abdominal Pain

APPENDICITIS
- see General Surgery, GS28
- most common cause of acute abdomen after 5 yr of age
- clinical features: low grade fever, abdominal pain, anorexia, N/V (after onset of pain), peritoneal signs (generalized peritonitis is a common presentation in infants/young children)
- treatment: surgical
- complications: perforation (common in young children), abscess

INTUSSUSCEPTION
- telescoping of segment of bowel into distal segment causing ischemia and necrosis

Epidemiology
- 90% idiopathic, children with CF or GJ tube at significantly increased risk; M:F = 3:1
- 50% between 3-12 mo, 75% before 2 yr of age

Pathophysiology
- usual site: ileocecal junction; jejunum in children with GJ tubes
- lead point of telescoping segment may be swollen Peyer's patches, Meckel's diverticulum, polyp, malignancy, HSP, structural abnormalities

Clinical Presentation
- “classic triad” (<25%) patients – abdominal pain, palpable mass, red currant jelly stools
- often preceded by URTI
- sudden onset of recurrent, paroxysmal, severe periumbilical pain with pain-free intervals
- later vomiting (may be bilious) and rectal bleeding (late finding)
- shock and dehydration; lethargy may be only presenting symptom

Diagnosis
- U/S, air enema

Management
- air enema can be therapeutic (reduces intussusception in 75% of cases), reduction under hydrostatic pressure, surgery rarely needed
- recurrence rate 10-15%, need to consider pathologic lead point
**Chronic Abdominal Pain**

**Epidemiology**
- prevalence: 10% of school children (peak at 8-10 yr), F>M

**Etiology**
- organic (<10%)
  - gastrointestinal
    - constipation (cause vs. effect), infectious
    - IBD, esophagitis, peptic ulcer disease, lactose intolerance
    - anatomic anomalies, masses
    - pancreatic, hepatobiliary
  - genitourinary causes: recurrent UTI, nephrolithiasis, chronic PID, Mittelschmerz
  - neoplastic
- functional abdominal pain (90%): can be diagnosed when there are no alarm symptoms or signs, physical exam is normal, and stool sample tests are negative for occult blood; no further testing is required, unless high suspicion for organic cause

**Clinical Presentation**
- clustering episodes of vague, crampy periumbilical/epigastric pain, vivid pain description
- seldom awakens child from sleep, less common on weekends
- aggravated by exercise, alleviated by rest
- psychological factors related to onset and/or maintenance of pain, school avoidance
- psychiatric comorbidity: anxiety, somatoform, mood, learning disorders, sexual abuse, eating disorders, elimination disorders
- diagnosis of exclusion

**Investigations**
- fecal occult blood and others based on clinical suspicion (CBC, ESR, urinalysis, etc.)

**Management**
- continue to attend school
- manage any emotional or family problems, counseling, CBT
- trial of high fiber diet, trial of lactose-free diet
- possible role for amitriptyline
- reassurance

**Prognosis**
- pain resolves in 30-50% of children within 2-6 wk of diagnosis
- 30-50% of children with functional abdominal pain have functional pain as adults (e.g. IBS)

**Abdominal Mass**

<table>

**Upper Gastrointestinal Bleeding**

- see Gastroenterology: G25
Lower Gastrointestinal Bleeding

- see Gastroenterology, G27

Etiology

- acute
  - infectious (bacterial, parasitic)
  - antibiotic-induced (C. difficile)
  - NEC in preterm infants
  - anatomic
  - malrotation/volvulus, intussusception
  - Meckel's diverticulitis
  - anal fissures, hemorrhoids
  - vascular/hematologic
  - HSP
  - HUS
  - coagulopathy

- chronic
  - anal fissures (most common)
  - colitis
  - IBD
  - allergic (milk protein)
  - structural
  - polyps (most are hamartomas)
  - neoplasms (rare)
  - coagulopathy

Physical Exam

- hemodynamic status, evidence of FTT, fever
- anal and rectal exam: tags, fissures, anal fistulas, polyps, foreign body, blood per rectum
- stool appearance
- NG aspirate
- lower GI bleed may present as melena (if it involves the small bowel) or hematochezia

Investigations

- stool cultures (C&S, C. difficile toxin)
- urinalysis and microscopy
- CBC, smear, differential, ESR, CRP, electrolytes, urea, Cr, INR, PTT, albumin, iron studies, amoeba titers
- radiologic investigations (including abdominal x-ray to rule out obstruction)
- Meckel's radionuclide scan

Management

- acute stabilization: ABCs, volume and blood replacement, bowel rest (NPO, NG tube)
- once stable, endoscopy and/or surgery as indicated

Genetics, Dysmorphisms, and Metabolism

Genetics

MECHANISMS OF INHERITANCE

Mendelian Inheritance

- disorders caused by mutation of one or both copies of a gene, inherited in one of two patterns:
  - autosomal: encoded by genes on one of 22 pairs of autosomes (chromosomes 1-22)
  - X-linked: encoded by a gene on the X chromosome

Triplet Repeat Expansions

- disorder in which trinucleotide repeats in certain genes exceed the normal number and result in altered expression of the gene or production of an abnormal protein (e.g. Fragile X syndrome, spinocerebellar ataxias, myotonic dystrophy, Huntington disease)

Imprinting Disorders

- imprinting: epigenetic process that involves methylation or acetylation of DNA, affecting gene expression
- imprinted genes are expressed differently depending on whether they are inherited from the mother or the father (parent-of-origin gene expression)
- occur when imprinted alleles are silenced (e.g. Prader-Willi syndrome, Angelman syndrome, Beckwith-Wiedemann syndrome)

Mitochondrial Inheritance

- disorders caused by mutations of the DNA present in mitochondria
- inheritance pattern: mother passes on the defect to all her children; father does not pass on the defect since embryo only receives mitochondria from the mother (in the egg)
METHODS OF GENETIC TESTING

• microarray analysis
  - a microarray is a collection of DNA probes attached to a solid surface
  - microarray analysis can identify small deletions or duplications of genetic material anywhere in the genome
  - indicated when there is developmental delay + one or more major malformations
• FISH: usually to identify a gain or loss of chromosomal material
• karyotype: microscopic analysis of all 46 chromosomes with a special stain that shows large changes in the number or structure of chromosomes

Genetic Anomalies

Minor and Major Anomalies

• minor anomaly: an unusual anatomic feature that is of no serious medical or cosmetic consequence to the patient
• major anomaly: anomaly that creates significant medical, surgical, or cosmetic problems for the patient

Mechanism for Anomalies

• malformation: results from an intrinsically abnormal developmental process (e.g. polydactyly)
• disruption: results from the extrinsic breakdown of, or interference with, an originally normal developmental process (e.g. amniotic band disruption sequence)
• deformation: alteration of the final form of a structure by mechanical forces (e.g. Potter deformation sequence)
• dysplasia: abnormal development that results in abnormal organization of cells into tissues (e.g. bone dysplasia)

Multiple Anomalies

• association: non-random occurrence of multiple independent anomalies that appear together more than would be predicted by chance but are not believed to have a single etiology (e.g. VACTERL)
• sequence: related anomalies that come from a single initial major anomaly or precipitating factor that changes the development of other surrounding or related tissues or structures (e.g. Potter sequence)
• syndrome: a pattern of anomalies that occur together and are caused by a single known or unknown cause (e.g. Down syndrome)

Approach to the Dysmorphic Child

• genetic disorders are the most common cause of infant death in developed countries

General Approach to the Dysmorphic Child

• Are the anomalies major or minor?
• What is the mechanism underlying the anomaly?
• Do the anomalies fit as part of an association, sequence, or syndrome?

History

• prenatal/obstetrical history (see Obstetrics, OB2) with particular attention to potential teratogenic exposures
• complete 3 generation family pedigree: consanguinity, stillbirths, neonatal deaths, specific illnesses, intellectual disability, multiple miscarriages, ethnicity

VACTERL Association

V  Vertebral dysgenesis
A  Anal atresia (imperforate anus)
± fistula
C  Cardiac anomalies
T-E TracheoEsophageal fistula
± esophageal atresia
R  Renal anomalies
L  Limb anomalies
Physical Exam

Figure 9. Physical exam of the dysmorphic child

Investigations
- screening for TORCH infections
- serial photographs if child is older
- x-rays for bony abnormalities
- cytogenetic studies
  - karyotype if recognized syndrome
  - chromosome microarray analysis (array comparative genomic hybridization) if development delay with one or more congenital anomalies
  - FISH if microdeletion syndrome or trisomy suspected
- biochemistry: specific enzyme assays
- single gene testing

Management
- prenatal counseling and assessing risk of recurrence
- referral for specialized pediatric or genetic care

Genetic Syndromes

</tbody>
</table>

**DUCHENNE MUSCULAR DYSTROPHY**

**Epidemiology**
- 1:4,000 males

**Etiology**
- one type of muscular dystrophy characterized by progressive skeletal and cardiac muscle degeneration
- X-linked recessive: 1/3 spontaneous mutations, 2/3 inherited mutations
- missing structural protein (dystrophin) → muscle fiber fragility → fiber breakdown → necrosis and regeneration

**Clinical Presentation**
- proximal muscle weakness by age 3, positive Gower’s sign, waddling gait, toe walking
- pseudohypertrophy of calf muscles (muscle replaced by fat) and wasting of thigh muscles
- decreased reflexes
- non-progressive delayed motor and cognitive development (dysfunctional dystrophin in brain)
- cardiomyopathy

**Diagnosis**
- molecular genetic studies of dystrophin gene (DMD) (first line)
- family history (pedigree analysis)
- increased CK (50-100x normal) and lactate dehydrogenase
- elevated transaminases
- muscle biopsy, EMG

**Management**
- supportive (e.g. physiotherapy, wheelchairs, braces), prevent obesity
- cardiac health monitoring and early intervention
- bone health monitoring and intervention (vitamin D, bisphosphonates)
- steroids (e.g. prednisone or deflazacort)
- surgical (for scoliosis)
- gene therapy trials underway

**Complications**
- patient usually wheelchair-bound by 12 yr of age
- early flexion contractures, scoliosis, osteopenia of immobility, increased risk of fracture
- death due to pneumonia/respiratory failure or CHF in 2nd-3rd decade

**Metabolic Diseases**
- inherited disorders of metabolism; often autosomal recessive
- infants and older children may present with FTT or developmental delay
- newborn screening includes metabolic disorders
**Table 21. Metabolic Disorders**

<td>Developmental delay, Bone crises (Gaucher), Deafness, blindness</td>
<td>(mucopolysaccharidoses)</td>
</tr>
</tbody>
</table>

**Initial Investigations**

- Important to send lab studies at initial presentation in order to facilitate immediate diagnosis and treatment.
- Check newborn screening results.
- Electrolytes, ABGs (calculate anion gap, rule out acidosis).
- CBC with differential and smear.
- Blood glucose (hypoglycemia seen with organic acidemia, fatty acid oxidation defects, and GSDs).
- Lactate, ammonium (hyperammononemia with urea cycle defects), plasma Ca²⁺ and Mg²⁺.
- Routine urinalysis: ketonuria must be investigated.
- Carnitine levels with acylcarnitine profile.
- Others: urate, urine nitroprusside, plasma amino acid screen, urine organic acids, CSF glycine, free fatty acids (3-β-hydroxybutyrate ratio >4 in fatty acid oxidation defect).
- Storage diseases: urine mucopolysaccharide and oligosaccharide screen.

**PHENYLKETONURIA**

**Epidemiology**

- 1:10,000, autosomal recessive disease.

**Etiology**

- Deficiency of phenylalanine hydroxylase prevents conversion of phenylalanine to tyrosine leading to build up of toxic metabolites.
- Mothers who have PKU may have infants with congenital abnormalities.

**Clinical Presentation**

- Baby is normal at birth, then develops a musty odor, eczema, hypertonia, tremors, and mental retardation.
- Hypopigmentation due to low tyrosine (fair hair, blue eyes).

**Management**

- PKU screening at birth.
- Dietary restriction of phenylalanine starting within the first 10 d of life.
- Duration of dietary restriction controversial – lifelong or until end of puberty; should be resumed during pregnancy to maintain normal phenylalanine levels.
GALACTOSEMIA

Epidemiology
- 1:60,000; autosomal recessive disease

Etiology
- most commonly due to deficiency of galactose-1-phosphate uridyltransferase leading to an inability to process lactose/galactose

Clinical Presentation
- signs of liver and renal failure, jaundice, FTT, and cataracts with ingestion of lactose/galactose

Management
- elimination of galactose from the diet (e.g. dairy, breast milk)
- most infants are fed a soy-based diet

Complications
- increased risk of sepsis, especially E. coli
- if the diagnosis is not made at birth, liver and brain damage may become irreversible

Hematology

Approach to Anemia

Physiologic Anemia
- high Hb (>170 g/L) and reticulocyte count at birth is caused by a hypoxic environment in utero
- after birth, levels start to fall due to shorter fetal RBC lifespan, decreased RBC production (during first 6-8 wk of life, there is virtually no erythropoiesis due to new O2 rich environment), and increasing blood volume secondary to growth
- lowest levels about 100 g/L at 8-12 wk age (earlier and more exaggerated in premature infants); levels rise spontaneously with activation of erythropoiesis
- no treatment usually required

Iron Deficiency Anemia
- most common cause of childhood anemia
- full term infants exhaust iron reserves by 6 mo of age
- premature infants have lower reserves, therefore exhausted by 2-3 mo of age
- common diagnosis between 6 mo–3 yr and 11-17 yr due to periods of rapid growth and increased iron requirements; adolescents also have poor diet and menstrual losses

Etiology
- children at risk (premature, LBW, low SES, First Nations, etc.)
- dietary risk factors: whole cow milk in first year of life
• age >6 mo: <2 servings/d of iron-fortified cereal, red meat, or legumes
• age <12 mo: use of low-iron formula (<10 mg/L), primary diet of cow, goat, or soy milk
• age 1-5 yr: >16-20 oz/d of non-fortified milk
• blood loss
  ▪ iatrogenic: repeated blood sampling (especially in hospitalized neonates)
  ▪ allergic: cow milk protein-induced colitis

Clinical Manifestation
• usually asymptomatic until marked anemia, pallor, fatigue, pica (eating non-food materials),
tachycardia, systolic murmur, angular chelitis, koilonychias

Investigations
• CBC: low Hb, MCV, and MCH, reticulocyte count normal or high (absolute number low)
• Mentzer index (MCV/RBC) can help distinguish iron deficiency anemia from thalassemia
  ▪ ratio <13 suggests thalassemia; ratio >13 suggests iron deficiency
• blood smear: hypochromic, microcytic RBCs, pencil shaped cells, poikilocytosis
• iron studies: low ferritin, other (low iron, high total iron binding capacity, high transferrin, low
  transferrin saturation)
• initial therapy: trial of iron

Prevention
• breastfed term infants: begin iron supplementation (1 mg/kg/d) at 4-6 mo, continuing until able
to eat ≥2 feeds/d of iron-rich foods
• non-breastfed (<50% of diet) term infants: give iron-fortified formula from birth
• premature infants: give iron supplements from 1 mo through to 1 yr of age
• no cow’s milk until 9-12 mo, early introduction of red meat and iron-rich vegetables: total daily
  iron should be 11 mg (age 6-12 mo), 7 mg (age 1-3 yr)
• universal screening of Hb levels recommended at 9 mo

Management
• encourage diverse, balanced diet, limit homogenized milk to 16-20 oz/d
• oral iron therapy: 6 mg/kg/d elemental iron, divided bid to tid, for 3 mo
  ▪ increased reticulocyte count in 2-3 d (peaks day 5-7)
  ▪ increased hemoglobin in 4-30 d
  ▪ repletion of iron stores in 1-3 mo
  ▪ repeat hemoglobin levels after 1 mo of treatment
• poor response to oral iron therapy: non-compliance, medication intolerance, ongoing blood
  loss, IBD, celiac disease, incorrect diagnosis

Complications
• can cause irreversible effects on development if untreated (behavioral and intellectual
deficiencies)
• angular chelitis, glossitis, koilonychia (spoon nails)

Vitamin K Deficiency
• HDNB due to relative deficiencies of vitamin K-dependent coagulation factors
  ▪ generalized bleeding; GI/intracranial hemorrhage
• IM injection at birth, can also be given orally (3 doses: at birth, 2-4 wk, 6-8 wk) but infants at
  higher risk of HDNB
• reason for administration at birth
  ▪ human milk contains small amounts of vitamin K, and infants require ingestion of large
  volumes of human milk to promote GI bacterial colonization
  ▪ until few days after birth, susceptible to vitamin K deficiency

Anemia of Chronic Disease
• see Hematology, H16

Sickle Cell Disease
• see Hematology, H21

Presentation
• newborn screen
• clinical disease presents at 5-6 mo of age after fall in fetal Hb
anemia, fever (medical emergency – infection is leading cause of death in SCD), jaundice, splenomegaly, crisis (dactylitis is often the first presentation)
sickle cell trait: asymptomatic (may have microscopic hematuria and later isothenuria)
vaso-occlusive crisis
due to obstruction of blood vessels by rigid, sickled cells → tissue hypoxia → cell death; presents as fever and pain in any organ; most commonly in long bones of arms and legs, chest, abdomen, CNS (stroke), dactylitis (in young children), priapism
acute chest crisis: fever, chest pain, progressive respiratory distress, increased WBC count, pulmonary infiltrates
aplastic crisis: depression of erythropoiesis (decreased reticulocyte count to <1%, decreased Hb), generally associated with infection (especially parvovirus B19)
acute splenic sequestration: sudden, massive pooling of red cells in spleen, splenomegaly, tender spleen, acute fall in hemoglobin, shock, increased reticulocyte count; splenic dysfunction (functional asplenia) by 5 yr of age secondary to auto-infarction; risk for sepsis from encapsulated organisms
risk of osteomyelitis with Salmonella
Other Manifestations
long-term complications: growth delay, bony abnormalities (e.g. avascular necrosis of femoral head), gallstones, retinopathy, restrictive lung disease (screen with PFTs), cardiomyopathy (screen with Echo), and pulmonary HTN
Management
acute crises
admit for supportive and symptomatic treatment
fluids (1.5x maintenance; 1x maintenance only if in chest crisis), analgesia (opioid, multi-modal), antibiotics (e.g. 3rd generation cephalosporins), incentive spirometry and ambulation to decrease risk of chest crisis
straight transfusions for symptomatic/significant anemia, evolving chest crisis
RBC exchange transfusion for impending stroke, severe chest crisis, persistent priapism
O2, if respiratory distress or chest crisis (with incentive spirometry)
CBC, reticulocyte counts, cultures if febrile, CXR, or LP if indicated
chronic
early aggressive treatment of infections, prophylactic antibiotics (daily oral penicillin)
pneumococcal, meningococcal, hepatitis B, Hib, and influenza vaccines
folate supplementation
hydroxyurea if frequent crises, history of acute chest syndrome (raises HbF level)
transcranial Doppler to assess risk of stroke
chronic transfusion program if history of stroke or abnormal transcranial Doppler
 genetic counseling and education
annual fundoscopic exam (after 10 yr old)
bi-annual screening for pulmonary HTN (after 12 yr old)
bi-annual chemistry and urinanalysis to monitor organ dysfunction
Thalassemia
see Hematology, H19
Hereditary Spherocytosis
see Hematology, H23
Glucose-6-Phosphate Dehydrogenase Deficiency
see Hematology, H23
G6PD deficiency protects against parasitism of RBCs (i.e. malaria)
## Bleeding Disorders

## Immune Thrombocytopenic Purpura

### Epidemiology
- most common cause of thrombocytopenia in childhood
- peak age: 2-6 yr, M=F
- incidence 5:100,000 children per yr

### Etiology
- caused by autoantibodies that bind to platelet membranes → Fc-receptor mediated splenic uptake → destruction of platelets

### Clinical Presentation
- 50% present 1-3 wk after viral illness (URTI, chicken pox)
- sudden onset of petechiae, purpura, epistaxis in an otherwise well child
- clinically significant bleed in only 3% (severe bleed more likely with platelet count <10) with <0.5% risk of intracranial bleed
- no lymphadenopathy, no hepatosplenomegaly
- labs: thrombocytopenia with normal RBC, WBC
- bone marrow aspirate only if atypical presentation (≥1 cell line abnormal, hepatosplenomegaly)
- differential diagnosis: leukemia, drug-induced thrombocytopenia, HIV, infection (viral), autoimmune (SLE, ALPS)

### Management
- observation vs. pharmacologic intervention highly debated; spontaneous recovery in >70% of cases within 3 mo
- treatment with IVIg or prednisone if mucosal or internal bleeding, platelets <10, or at risk of significant bleeding (surgery, dental procedure, concomitant vasculitis or coagulopathy)
- life-threatening bleed: additional platelet transfusion ± emergency spleenectomy
- persistent (>3-12 mo) or chronic (>12 mo): re-evaluate; treat if symptoms persist
- supportive: avoid contact sports and ASA/NSAIDs

## Hemophilia

- see Hematology, H31

## von Willebrand’s Disease

- see Hematology, H30
Oncology

- cancer is the second most common cause of death after injuries in children after 1 yr of age
- cause is rarely known, but increased risk for children with: chromosomal syndromes (e.g. Trisomy 21), prior malignancy, neurocutaneous syndromes, immunodeficiency syndromes, family history, exposure to radiation, chemicals, biologic agents
- leukemias are the most common type of pediatric malignancy (40%), followed by brain tumors (20%), and lymphomas (15%)
- some malignancies are more prevalent in certain age groups:
  - newborns: neuroblastoma, Wilms’ tumor, retinoblastoma
  - infancy and childhood: leukemia, neuroblastoma, Wilms’ tumor, retinoblastoma
  - adolescence: lymphoma, gonadal tumors, bone tumors
- unique treatment considerations in pediatrics because radiation, chemotherapy, and surgery can impact growth and development, endocrine function, and fertility
- good prognosis: treatments have led to remarkable improvements in overall survival and cure rates for many pediatric cancers (>80%)

Lymphadenopathy

Clinical Presentations
- features of malignant lymphadenopathy: firm, discrete, non-tender, enlarging, immobile ± suspicious mass/imaging findings ± constitutional symptoms
- fluctuance, warmth, or tenderness are more suggestive of benign nodes (infection)

Differential Diagnosis
- infection
  - viral: URTI, EBV, CMV, adenovirus, HIV
  - bacterial: *S. aureus*, GAS, anaerobes, *Mycobacterium* (e.g. TB), cat scratch disease (*Bartonella*)
  - other: fungal, protozoan, *Rickettsia*
- autoimmune: rheumatoid arthritis, SLE, serum sickness
- malignancy: lymphoma, leukemia, metastatic solid tumors
- storage diseases: Niemann-Pick, Gaucher’s
- other: sarcoidosis, Kawasaki disease, histiocytoses

Investigations
- generalized lymphadenopathy
  - CBC and differential, blood culture
  - uric acid, LDH
  - ANA, RF, ESR
  - EBV/CMV/HIV serology
  - toxoplasma titer
  - fungal serology
  - CXR
  - TB tests
  - biopsy
- regional lymphadenopathy
  - period of observation if asymptomatic
  - trial of oral antibiotics
  - ultrasound
  - biopsy (especially if persistent >6 wk and/or constitutional symptoms)

Leukemia

- see Hematology, H37, H40, H43, H48

Epidemiology
- mean age of diagnosis 2-5 yr but can occur at any age
- heterogeneous group of diseases
  - ALL (80%)
  - AML (15%)
  - CML (<5%)
- children with DS are 15x more likely to develop leukemia

Clinical Presentation
- infiltration of leukemic cells into bone marrow results in bone pain and bone marrow failure (anemia, neutropenia, thrombocytopenia)
- infiltration into tissues results in lymphadenopathy, hepatosplenomegaly, CNS manifestations, testicular disease
- fever, fatigue, weight loss, bruising, and easy bleeding
• hyperleukocytosis (total WBC >10.0 x 10^9/dL) is a medical emergency
  ▪ presents clinically with respiratory or neurological distress caused by hyperviscosity of blood and leukostasis
  ▪ risk of ICH, pulmonary leukostasis syndrome, tumor lysis syndrome
  ▪ management: fluids, allopurinol/rasburicase, fresh frozen plasma/platelets to correct thrombocytopenia, induction chemotherapy, avoid transfusing RBCs unless symptomatic (and then use very small volumes)

Management
• combination chemotherapy using non-cross resistant chemotherapy agents, allogeneic stem cell transplantation for high-grade or recurrent disease
• supportive care and management of treatment complications
  ▪ febrile neutropenia: see Infectious Diseases, ID46
  ▪ tumor lysis syndrome: see Hematology, H52

Prognosis
• 80-90% 5 yr event-free survival for ALL, 50-60% 5 yr survival for AML
• patients are stratified into standard risk and high risk based on WBC and age; other prognostic factors include presence of CNS/testicular disease, immunophenotype, cytogenetics, and initial response to therapy (most important prognostic variable)

Lymphoma

• see Hematology, H44

Epidemiology
• Hodgkin lymphoma: incidence is bimodal, peaks at ages 15-34 and >50 yr old
• non-Hodgkin lymphoma: incidence peaks at 7-11 yr

Clinical Presentation
• Hodgkin lymphoma
  ▪ most common presentation is persistent, painless, firm, cervical, or supraclavicular lymphadenopathy
  ▪ can present as persistent cough or dyspnea (secondary to mediastinal mass) or less commonly as splenomegaly, axillary, or inguinal lymphadenopathy
  ▪ constitutional symptoms in 30% of children
• non-Hodgkin lymphoma
  ▪ generally categorized into lymphoblastic, large cell, and Burkitt’s/Burkitt’s-like lymphoma
  ▪ rapidly growing tumor with distant metastases (unlike adult non-Hodgkin lymphoma)
  ▪ signs and symptoms related to disease site: most commonly abdomen, chest (mediastinal mass), head and neck region

Management
• Hodgkin lymphoma
  ▪ combination chemotherapy and radiation
  ▪ aimed at limiting cumulative doses of anthracyclines (toxic to heart) and alkylators (risk of second malignancy, infertility) and limiting dose and field of radiation
  ▪ increasing role for use of PET scanning to assess early disease response and plan therapy
• non-Hodgkin lymphoma
  ▪ combination chemotherapy
  ▪ no added benefit of radiation in pediatric protocols

Prognosis
• Hodgkin lymphoma: >90% 5 yr survival
• non-Hodgkin lymphoma: 75-90% 5 yr survival

Brain Tumors

• see Neurosurgery, NS10, NS38

Wilms’ Tumor (Nephroblastoma)

Epidemiology
• usually diagnosed between 2-5 yr M=F
  ▪ most common primary renal neoplasm of childhood
  ▪ 5-10% of cases both kidneys are affected (simultaneously or in sequence)
**Differential Diagnosis**
- hydronephrosis, polycystic kidney disease, renal cell carcinoma, neuroblastoma

**Clinical Presentation**
- 80% present with asymptomatic, unilateral abdominal mass
- may also present with HTN, gross hematuria, abdominal pain, vomiting
- may have pulmonary metastases at time of diagnosis (respiratory symptoms)

**Associated Congenital Abnormalities**
- WAGR syndrome (Wilms' tumor, Aniridia, Genital anomalies, mental Retardation) with 11p13 deletion
- Beckwith-Wiedemann syndrome
  - characterized by enlargement of body organs (especially tongue), hemihypertrophy, renal medullary cysts, and adrenal cytomegaly
  - also at increased risk for developing hepatoblastoma, and less commonly adrenocortical tumors, neuroblastomas, and rhabdomyosarcomas
- Denys-Drash syndrome: characterized by gonadal dysgenesis and nephropathy leading to renal failure

**Management**
- staging ± nephrectomy
- chemotherapy, radiation for higher stages

**Prognosis**
- 90% long-term survival

---

**Neuroblastoma**

**Epidemiology**
- most common cancer occurring in first year of life
- neural crest cell tumor arising from sympathetic tissues (neuroblasts)

**Clinical Presentation**
- can originate from any site in sympathetic nervous system, presenting as mass in neck, chest, or abdomen (most common site is adrenal gland)
- signs and symptoms of disease vary with location of tumor
  - thoracic: dyspnea, Horner's syndrome
  - abdomen: palpable mass
  - spinal cord compression
- metastases are common at presentation (>50% present with advanced stage disease):
  - usually to bone or bone marrow (presents as bone pain, limp)
  - can also present with periorbital ecchymoses, abdominal pain, emesis, fever, weight loss, anorexia, hepatomegaly, "blueberry muffin" skin nodules
- paraneoplastic: HTN, palpitations, sweating (from excessive catecholamines), diarrhea, FTT (from vasoactive intestinal peptide secretion), opsomyoclonus
- diagnostic criteria (either of the following)
  - unequivocal histologic diagnosis from tumor tissue biopsy
  - evidence of metastasis to bone marrow ("rosettes") on aspirate analysis, with concomitant elevation of urine or serum catecholamine metabolite (VMA, HVA) levels

**Management**
- depends on prognostic factors and may include combination of: surgery, radiation, chemotherapy, autologous stem cell transplantation, immunotherapy

**Prognosis**
- prognosis is often poor due to late detection
- good prognostic factors
  - "age and stage" are important determinants of better outcome: 12-18 mo, stage I, II, IV-S disease ("S" designates a "Special" classification only pertaining to infants)
  - primary site: posterior mediastinum and neck
  - low serum ferritin
  - specific histology
  - tumor cell markers: aneuploidy, absent MYCN oncogene amplification

---

**Bone Tumors**
- see Orthopedics, OR43
**Fever**

**Definition**
- fever: no generally accepted definition, a practical definition is >100.4°F/38°C oral or rectal
- fever without a source/focus: acute febrile illness (typically <10 d duration) with no cause of fever even after careful history and physical
- fever of unknown origin: daily or intermittent fevers for at least 2 consecutive weeks of uncertain cause after careful history and physical, and initial laboratory assessment

**Etiology**
- infectious: anatomic approach (CNS, ears, upper and lower respiratory tract, GI, GU, skin, soft tissue, bones and joints, etc.)
- inflammatory: mainly autoimmune (Kawasaki disease, JIA, IBD, SLE, etc.)
- malignancy: childhood cancers (leukemia, lymphoma, neuroblastoma, etc.)
- miscellaneous: dehydration, drugs and toxins, post-immunization, familial dysautonomia, factitious disorder, etc.

**Diagnosis**
- history: duration, height and pattern of fever, associated symptoms, exposures, constitutional symptoms, recent antipyretic use, ethnic or genetic background, day care, sick contacts, travel, tick bites
- physical exam: toxic vs. non-toxic, vitals, growth, complete exam of the skin, HEENT, chest, abdomen, lymph nodes, genitalia
- investigations: guided by history, physical exam, and clinical suspicion

**Evaluation of Neonates and Infants with Fever**
- several protocols exist that attempt to identify neonates and young infants at low risk of serious bacterial infection (e.g. Rochester criteria)
  - such protocols are not as sensitive in the 1-28 d age group; therefore, febrile neonates should be considered high risk regardless of clinical presentation and laboratory findings

**Management**
- admit to hospital if appropriate
- treat the source if known
- replace fluid losses (e.g. from vomiting, diarrhea, etc.); maintenance fluid needs are higher in febrile child
- reassure parents that most fevers are benign and self-limited
- antipyretics (acetaminophen and/or ibuprofen) are not necessary in most cases, but can be given if child is uncomfortable

**Rochester Criteria – Developed to Identify Infants ≤60 d of Age with Fever at Low Risk of Serious Bacterial Infection**

**Figure 11. Approach to the febrile child**

**NOTES**
1. Full Septic Workup (SWU) – blood C&S, CBC and differential, urine R&M, C&S, LP, CXR if respiratory symptoms, stool C&S if GI symptoms
2. Follow-up is crucial – if adequate follow-up is not assured, a more aggressive diagnostic and therapeutic approach may be indicated
3. Low-risk (Rochester) criteria
4. Considerable practice variation exists in terms of empiric antibiotic treatment
5. Important principles – the younger the child, the greater the difficulty to clinically assess the degree of illness
Acute Otitis Media

Definition
All of:
1. presence of middle ear effusion
2. presence of middle ear inflammation
3. acute onset of symptoms of middle ear effusion and inflammation

Epidemiology
- 60-70% of children have at least 1 episode of AOM before 3 yr of age
- 18 mo-6 yr most common age group
- peak incidence January to April
- one third of children have had ≥3 episodes by age 3

Etiology
- S. pneumoniae: 32% of cases (incidence decreasing due to pneumococcus vaccine)
- H. influenzae (non-typeable): 28% of cases
- M. catarrhalis: 14% of cases
- S. aureus and S. pyogenes (all β-lactamase producing)
- anaerobes (newborns)
- Gram-negative enterics (infants)
- viral

Predisposing Factors
- Eustachian tube dysfunction/obstruction
  - swelling of tubal mucosa: URI, allergic rhinitis, chronic rhinosinusitis
  - obstruction/infiltration of Eustachian tube ostium: adenoid hypertrophy (not due to obstruction but by maintaining a source of infection), barotrauma (sudden changes in air pressure)
  - inadequate tensor palati function: cleft palate (even after repair)
  - abnormal Eustachian tube: DS (horizontal position of Eustachian tube), Crouzon syndrome, cleft palate, and Apert syndrome
  - disruption of action of
cilia of Eustachian tube: Kartagener’s syndrome
- mucus secreting cells
- capillary network that provides humoral factors, neutrophils, phagocytic cells
- immunosuppression/deficiency due to chemotherapy, steroids, DM, hypogammaglobulinemia, CF

Risk Factors
- bottle feeding, pacifier use
- second-hand smoke
- crowded living conditions (day care/group child care facilities) or sick contacts
- male
- family history

Pathogenesis
- obstruction of Eustachian tube → air absorbed in middle ear → negative pressure (an irritant to middle ear mucosa) → edema of mucosa with exudate/effusion → infection of exudate from nasopharyngeal secretions

Clinical Features
- triad of otalgia, fever (especially in younger children), and conductive hearing loss
- rarely tinnitus, vertigo, and/or facial nerve paralysis
- otorrhea if tympanic membrane perforated
- infants/toddlers: ear-tugging (this alone is not a good indicator of pathology), hearing loss, balance disturbances (rare), irritable, poor sleeping, vomiting and diarrhea, anorexia
- otoscopy of TM: hyperemia, bulging, pus may be seen behind TM, loss of landmarks (e.g. handle and long process of malleus not visible)

Diagnosis and Management
- Diagnose AOM if:
  - moderate to severe bulging of TM or new onset of otorrhea not due to otitis externa
  - mild bulging of tympanic membrane and recent (<48 h) ear pain or intense erythema of TM
  - do not diagnose AOM if no middle ear effusion (based on pneumatic otoscopy or tympanometry)
- antibiotic treatment hastens resolution: 10 d course
  - 1st line
    - amoxicillin 75-90 mg/kg/d divided into two doses: safe, effective, and inexpensive
    - if penicillin allergic: macrolide (clarithromycin, azithromycin – high resistance), trimethoprim-sulphamethoxazole (Bactrim®)
- antibiotic treatment hastens resolution: 10 d course

Clinical Assessment of AOM in Pediatrics
JAMA 2010;304:2161-2169
In assessment of AOM in pediatrics, ear pain is the most useful symptom with a LR between 3-7.3. (Useful otoscopic signs include erythematous [LR 8.4, 95% CI 7-11], cloudy [LR 34, 95% CI 28-42], bulging [LR 51, 95% CI 38-73], and immobile tympanic membrane on pneumatic otoscopy [LR 31, 95% CI 26-37].)

The Diagnosis and Management of Acute Otitis Media
Pediatrics 2013;131:e664-e699

Strong Recommendations
- Management of AOM should include an assessment of pain, if pain is present, the clinician should recommend treatment to reduce pain.
- Severe AOM in young children:
  - Prescribe antibiotic therapy for AOM (bilateral or unilateral) in children 6 mo and older with severe signs or symptoms (i.e. moderate or severe otalgia or otalgia for at least 48 h or temperature 102.2°F [39°C] or higher).
  - Recommended pneumococcal conjugate vaccine to all children according to vaccination schedule.
- Recommendations
  - Diagnose AOM in children who present with moderate to severe bulging of the TM or new onset of ototrauma not due to acute otitis externa.
  - Diagnose AOM in children who present with mild bulging of the TM and recent (<48 h) onset of ear pain (tugging, tugging, rubbing of the ear in a nonthermal child) or intense erythema of the TM.
  - Non-severe AOM in young children:
    - Prescribe antibiotic therapy for bilateral AOM in children 6 mo through 23 mo of age without severe signs or symptoms (i.e. mild otalgia for less than 48 h and temperature less than 102.2°F [39°C]).
    - Either prescribe antibiotic therapy or offer observation with close follow-up based on joint decision-making with the parent(s)/caregiver(s) for unilateral AOM in children 6-23 mo of age or bilateral or unilateral AOM in children ≥24 mo without severe signs or symptoms; when observation is used, a mechanism must be in place to ensure follow-up and begin antibiotic therapy if the child worsens or fails to improve within 48-72 h of onset of symptoms.
    - Prescribe amoxicillin for AOM when a decision to treat with antibiotics has been made and the child has not received amoxicillin in the past 30 d or the child does not have concurrent otitis externa.
    - Prescribe antibiotics with additional β-lactamase coverage for AOM when a decision to treat with antibiotics has been made and the child has not received amoxicillin in the last 30 d or has concurrent otitis externa or has a history of recurrent AOM unresponsive to amoxicillin.
    - Reassess the patient if the caregiver reports that the child’s symptoms have worsened or failed to respond to the initial antibiotic treatment within 48-72 h and determine whether a change in therapy is needed.
    - Do NOT prescribe prophylactic antibiotics to reduce the frequency of episodes of AOM in children with recurrent AOM.
    - Recommend annual influenza vaccine to all children according to vaccination schedule.
    - Encourage exclusive breastfeeding for at least 6 mo.
    - Encourage avoidance of tobacco smoke exposure.
- Options
  - Offer tympanostomy tubes for recurrent AOM (3 episodes in 6 mo or 4 episodes in 1 yr with 1 episode in the preceding 6 mo).
2nd line
- amoxicillin-clavulanic acid (Augmentin®)
- cephalosporins: cefuroxime axetil (Zinacef®), ceftriaxone (Rocephin®), cefaclor (Ceclor®), cefixime (Suprax®)
- AOM deemed unresponsive if clinical signs/symptoms and otoscopic findings persist beyond 48 h of antibiotic treatment

- symptomatic therapy
  - antipyretics/analgesics (e.g. acetaminophen)
  - decongestants: may relieve nasal congestion but does not treat AOM

- prevention
  - parent education about risk factors
  - antibiotic prophylaxis: amoxicillin or macrolide shown effective at half therapeutic dose
  - pneumococcal and influenza vaccine

- surgery
  - choice of surgical therapy for recurrent AOM depends on whether local factors (Eustachian tube dysfunction) are responsible (use ventilation tubes), or regional disease factors (tonsillitis, adenoid hypertrophy, sinusitis) are responsible

Complications
- extracranial: hearing loss and speech delay (secondary to persistent middle ear effusion), TM perforation, extension of suppurative process to adjacent structures (mastoiditis, petrositis, labyrinthitis), cholesteatoma, facial nerve palsy, middle ear atelectasis, ossicular necrosis, vestibular dysfunction
- intracranial: meningitis, epidural and brain abscess, subdural empyema, lateral and cavernous sinus thrombosis, carotid artery thrombosis

Otitis Media with Effusion

Definition
- presence of fluid in the middle ear without signs or symptoms of ear infection

Epidemiology
- most common cause of pediatric hearing loss
- not exclusively a pediatric disease
- follows AOM frequently in children
- middle ear effusions have been shown to persist following an episode of AOM for 1 mo in 40% of children, 2 mo in 20%, and >3 mo in 10%

Risk Factors
- same as AOM

Clinical Features
- conductive hearing loss ± tinnitus
- fullness – blocked ear
- ± pain, low grade fever
- otoscopy of TM
  - discoloration – amber or dull gray with "glue" ear
  - meniscus fluid level behind TM
  - air bubbles
  - retraction pockets/TM atelectasis
- most reliable finding with pneumatic otoscopy is immobility

Treatment
- expectant: 90% resolve by 3 mo
- document hearing loss with audiogram (see Otolaryngology Figure 16B and Figure 17B, OT10)
- no statistical proof that antihistamines, decongestants, antibiotics clear disease faster
- surgery: myringotomy ± ventilation tubes ± adenoidectomy (if enlarged or on insertion of second set of tubes after first set falls out)
- ventilation tubes to equalize pressure and drain ear

Complications of OME
- hearing loss, speech delay, learning problems in young children
- chronic mastoiditis
- ossicular erosion
- cholesteatoma especially when retraction pockets involve pars flaccida
- retraction of tympanic membrane, atelectasis, ossicular fixation

Gastroenteritis
- see Gastroenterology, P36

HIV Infection
- see Infectious Diseases, ID29

<td>Significant pruritis Enanthem: vesicular lesions which may become pustular or ulcerate</td>
<td>Supportive Avoid salicylates (due to risk of Reye syndrome) Consider antivirals Respiratory and contact isolation, report to Public Health Prevention: varicella vaccine</td>
<td>Skin: bacterial suprainfection, necrotizing fasciitis CNS: acute encephalitis and cerebellar ataxia Systemic: hepatitis, DIC Congenital varicella syndrome if intrapartum infection</td>
</tr>
</tbody>
</table>
Infectious Mononucleosis

Definition
- systemic viral infection caused by EBV with multivisceral involvement; often called “the great imitator”

Epidemiology
- peak incidence between 15-19 yr old
- ~50% of children in developed countries have a primary EBV infection by 5 yr old, but <10% of children develop clinical infection

Etiology
- EBV: a member of herpesviridae
- transmission is mainly through infected saliva (“kissing disease”) and sexual activity (less commonly); incubation period of 1-2 mo

Risk Factors
- infectious contacts, sexually active, multiple sexual partners in the past

History
- prodrome: 2-3 d of malaise, anorexia
- infants and young children: often asymptomatic or mild disease
- older children and adolescents: malaise, fatigue, fever, sore throat, abdominal pain (often LUQ), headache, myalgia

Physical Exam
- classic triad: febrile, generalized non-tender lymphadenopathy, pharyngitis/tonsillitis (exudative)
- ± hepatosplenomegaly
- ± periorbital edema, ± rash (urticarial, maculopapular, or petechial) – more common after inappropriate treatment with β-lactam antibiotics
- any “-itis” (including arthritis, hepatitis, nephritis, myocarditis, meningitis, encephalitis, etc.)

Investigations
- heterophil antibody test (Monospot® test)
  - 85% sensitive in adults and older children, but only 50% sensitive if <4 yr of age
  - false positive results with HIV, SLE, lymphoma, rubella, parvovirus
- EBV titers
- CBC and differential, blood smear: atypical lymphocytes, lymphocytosis, Downey cells ± anemia ± thrombocytopenia
- throat culture to rule out streptococcal pharyngitis

Management
- supportive: adequate rest, hydration, saline gargles, and analgesics for sore throat
- splenic enlargement is often not clinically apparent so all patients should avoid contact sports for 6-8 wk
- if airway obstruction secondary to nodal and/or tonsillar enlargement is present (especially younger children), admit for steroid therapy
- acyclovir does NOT reduce duration of symptoms or result in earlier return to school/work

Prognosis
- most acute symptoms resolve in 1-2 wk, though fatigue may last for months
- short-term complications: splenic rupture, Guillain-Barré syndrome

Infectious Pharyngitis/Tonsillitis

Definition
- inflammation of the pharynx, especially the tonsils if present, causing a sore throat

Etiology
- viral (~80%): adenoviruses, enteroviruses, coxsackie, upper respiratory tract viruses, EBV, CMV
- bacterial (~20%): mainly GAS, M. pneumoniae (older children), N. gonorrhoeae (sexually active), C. diphtheriae (unvaccinated)
- fungal: Candida

Epidemiology
- season: GAS pharyngitis more common in late winter or early spring; viral all year long
- age: GAS pharyngitis peak incidence at 5-12 yr of age and uncommon <3 yr; viral pharyngitis affects all ages
**History**
- **GAS:** sore throat (may be severe), fever, malaise, headache, abdominal pain, N/V, absence of other URTI symptoms
- **viral:** sore throat (often mild), conjunctivitis, cough, rhinorrhea, hoarseness, diarrhea, flu-like symptoms (fever, malaise, myalgias)

**Physical Exam**
- **GAS:** febrile, pharyngeal/tonsillar erythema and exudates, enlarged (>1 cm) and tender anterior cervical lymph nodes, palatal petechiae, strawberry tongue, scarlatiniform rash
- **viral:** afebrile, absent/mild tonsillar exudates, minor and non-tender adenopathy, viral exanthems

**Investigations**
- no single sign or symptom reliably identifies GAS as the causative organism in children with sore throat
- scores are used to predict if throat culture will be positive (e.g. McIsaac Criteria)
  - these score systems have not been found to be sensitive or specific enough to diagnose GAS in children and adolescents with sore throat
- suspected diagnosis of GAS pharyngitis should be confirmed with a rapid streptococcal antigen test and a follow-up throat culture if the rapid test is negative

**Management**
- **antibiotics** (for GAS/S. pyogenes)
  - penicillin V or amoxicillin or erythromycin (if penicillin allergy) x 10 d
  - can prevent rheumatic fever if given within 9 d of symptoms; does NOT alter risk of post-streptococcal GN
- supportive: hydration and acetaminophen for discomfort due to pain and/or fever
- follow-up: if uncomplicated course, no follow-up or post-antibiotic throat cultures needed
- prophylaxis: consider tonsillectomy for proven, recurrent streptococcal tonsillitis

**Complications**
- preventable with antibiotics: AOM, sinusitis, cervical adenitis, mastoiditis, retropharyngeal/peritonsillar abscess, sepsis
- immune-mediated complications: scarlet fever, acute rheumatic fever, post-streptococcal GN, reactive arthritis, pediatric autoimmune neuropsychiatric disorder associated with group A Streptococci (i.e. PANDAS)

**SCARLET FEVER**
- diffuse erythematous eruption
- delayed-type hypersensitivity reaction to pyrogenic exotoxin produced by GAS
- acute onset of fever, sore throat, strawberry tongue
- 24-48 h after pharyngitis, rash begins in the groin, axillae, neck, antecubital fossa; Pastia’s lines may be accentuated in flexural areas
- within 24 h, sandpaper rash becomes generalized with perioral sparing, non-pruritic, non-painful, blanchable
- rash fades after 3-4 d, may be followed by desquamation
- treatment is penicillin, amoxicillin, or erythromycin x 10 d

**RHEUMATIC FEVER**
- inflammatory disease due to antibody cross-reactivity following GAS infection
- affects ~1:10,000 children in developed world; much more prevalent in developing nations; peak incidence at 5-15 yr of age
- mainly a clinical diagnosis based on Jones Criteria (revised):
  - requires 2 major OR 1 major and 2 minor PLUS evidence of preceding strep infection (history of scarlet fever, GAS pharyngitis culture, positive rapid Ag detection test, ASOTs)
  - treatment: penicillin or erythromycin for acute course x 10 d, prednisone if severe carditis
  - secondary prophylaxis with daily penicillin or erythromycin
- complications
  - acute: myocarditis, conduction system aberrations (sinus tachycardia, atrial fibrillation), valvulitis (acute MR), pericarditis
  - chronic: valvular heart disease (mitral and/or aortic insufficiency/stenosis), infectious endocarditis ± thromboembolic phenomenon
  - onset of symptoms usually after 10-20 yr latency from acute carditis of rheumatic fever
POST-STREPTOCOCCAL GLOMERULONEPHRITIS
• most common in children aged 4-8 yr old; M>F
• antigen-antibody mediated complement activation with diffuse, proliferative GN
• occurs 1-3 wk following initial GAS infection (skin or throat)
• clinical presentation varies from asymptomatic, microscopic and macroscopic hematuria (colored urine) to all features of nephritic syndrome (see P81)
• diagnosis is confirmed with elevated serum antibody titers against streptococcal antigens (ASOT, anti-DNAse B), low serum complement (C3)
• management
  ▪ symptomatic: fluid and sodium restrictions; loop diuretics for HTN and edema
  ▪ in severe cases, may require dialysis if renal function significantly impaired
  ▪ treat with penicillin or erythromycin if evidence of persistent GAS infection
• 95% of children recover completely within 1-2 wk; 5-10% have persistent hematuria

Meningitis

Definition
• inflammation of the meninges surrounding the brain and spinal cord

Epidemiology
• peak age: 6-12 mo; 90% of cases occur in children <5 yr old

Etiology
• viral: enteroviruses, HSV
• bacterial: age-related variation in specific pathogens
• fungal and parasitic meningitis also possible
• most often due to hematogenous spread or direct extension from a contiguous site

Risk Factors
• unvaccinated
• immunocompromised: asplenia, DM, HIV, prematurity
• recent or current infections: AOM, sinusitis, orbital cellulitis
• neuroanatomical: congenital defects, dermal sinus, neurosurgery, cochlear implants, recent head trauma
• exposures: day care centers, household contact, recent travel

History
• signs and symptoms variable and dependent on age, duration of illness, and host response to infection
• infants: fever, lethargy, irritability, poor feeding, N/V, diarrhea, respiratory distress, seizures
• children: fever, headache, photophobia, N/V, confusion, back/neck pain/stiffness, lethargy, irritability

Physical Exam
• infants: toxic, hypothermia, bulging anterior fontanelle, respiratory distress, apnea, petechial/purpuric rash, jaundice
• children: toxic, LOC, nuchal rigidity, Kernig’s and Brudzinski’s signs, focal neurologic findings, petechial/purpuric rash

Investigations
• blood work: CBC, electrolytes, Cr, BUN, glucose, C&S
• LP required for definitive diagnosis
  ▪ Gram stain, bacterial C&S, WBC count and differential, RBC count, glucose, protein concentration
  ▪ acid-fast stain if suspect TB
  ▪ PCR for specific bacteria if available (helpful if already treated with antibiotics)
  ▪ urinalysis and urine C&S in infants, Gram stain and culture of petechial/purpuric lesions
  ▪ HSV and enterovirus PCR if suspected

Signs of Meningismus
BONK on the head
Brudzinski’s sign
Opisthotonos*
Nuchal rigidity
Kernig’s sign
*Opisthotonos: rigid spasm of the body, with the back fully arched and the heels and head bent back

Management
- support care
  - preservation of adequate cerebral perfusion by maintaining normal BP and managing ↑ ICP
  - close monitoring of fluids, electrolytes, glucose, acid-base disturbances, coagulopathies
- bacterial meningitis
  - if suspected or cannot be excluded, commence empiric antibiotic therapy while awaiting cultures or if LP contraindicated or delayed
  - adjuvant dexamethasone BEFORE antibiotic for Hib meningitis; consider for those >6 wk with pneumococcal meningitis
  - isolation with appropriate infection control procedures until 24 h after culture-sensitive antibiotic therapy
  - fluid restrict if any concern for SIADH
  - hearing test
  - report to Public Health; prophylactic antibiotics for close contacts of Hib and N. meningitidis meningitis

</tbody>
</table>

- viral meningitis
  - mainly supportive (except for HSV)
  - acyclovir for HSV meningitis
  - report to Public Health
  - prophylaxis: appropriate vaccinations significantly decrease incidence of bacterial meningitis (see Routine Immunization, P3)

Complications
- mortality: neonate 15-20%, children 4-8%; pneumococcus > meningococcus > Hib
- acute: SIADH, subdural effusion/empyema, brain abscess, disseminated infection (osteomyelitis, septic arthritis, abscess), shock/DIC
- chronic: hearing loss, neuromotor/cognitive delay, learning disabilities, neurological deficit, seizure disorder, hydrocephalus

Mumps

Definition
- acute, self-limited viral infection that is most commonly characterized by adenitis and swelling of the parotid glands

Epidemiology
- incidence has declined since introduction of two-dose MMR vaccination schedule
- average of 25 reported cases per yr
- majority of reported cases in children between 5-10 yr of age

Etiology
- mumps virus (RNA virus of the genus Rubulavirus in the Paramyxoviridae family)
- transmission via respiratory droplets, direct contact, fomites
- incubation period: 14-25 d
• infectivity period: 7 d pre-parotitis to 5 d post-parotitis
• upper respiratory tract → lymph nodes → salivary glands, gonads, pancreas, meninges, kidney, heart, thyroid

History
• non-specific prodome of fever, headache, malaise, myalgias (especially neck pain)
• usually followed within 48 h by parotid swelling secondary to parotitis (bilateral, preauricular, ear pushed up and out)
• parotid gland is tender and pain worsened with spicy or sour foods
• one third of infections do not cause clinically apparent salivary gland swelling and may simply present as an URTI

Investigations
• clinical diagnosis, but may be confirmed with IgM positive serology within 4 wk of acute infection
  ▪ may also use PCR or viral cultures from oral secretions, urine, blood, and CSF
  ▪ blood work: CBC (leukopenia with relative lymphocytosis), serum amylase (elevated)

Management
• mainly supportive: analgesics, antipyretics, warm or cold packs to parotid may be soothing
• admit to hospital if serious complications (meningitis, pancreatitis)
• droplet precautions recommended until 5 d after onset of parotid swelling
• prophylaxis: routine vaccination (see Routine Immunization, P3)

Complications
• common: aseptic meningitis, orchitis/oophoritis
• less common: encephalitis, pancreatitis, thyroiditis, myocarditis, arthritis, GN, ocular complications, hearing impairment

Pertussis

Definition
• prolonged respiratory illness characterized by paroxysmal coughing and inspiratory “whoop”

Epidemiology
• ~10 million children <1 yr old affected worldwide, causes up to 400,000 deaths per yr
• greatest incidence among children <1 yr (not fully immunized) and adolescents (waning immunity)

Etiology
• Bordetella pertussis: Gram negative pleomorphic rod
• highly contagious; transmitted via respiratory droplets released during intense coughing
• incubation period: 6-20 d; most contagious during catarrhal phase but may remain contagious for weeks after

History
• prodromal catarrhal stage
  ▪ lasts 1-7 d; URTI symptoms (coryza, mild cough, sneezing) with NO or LOW-GRADE fever
• paroxysmal stage
  ▪ lasts 4-6 wk; characterized by paroxysms of cough (“100 day cough”), sometimes followed by inspiratory whoop (“whooping cough”)
  ▪ infants <6 mo may present with post-tussive apnea, whoop is often absent
  ▪ onset of attacks precipitated by yawning, sneezing, eating, physical exertion
  ▪ ± post-tussive emesis, may become cyanotic before whoop
• convalescent stage
  ▪ lasts 1-2 wk; characterized by occasional paroxysms of cough, but decreased frequency and severity
  ▪ non-infectious but cough may last up to 6 mo

Investigations
• NP specimen using aspirate or NP swab
  ▪ gold standard: culture using special media (Regan-Lowe agar)
  ▪ PCR to detect pertussis antigens
• blood work: CBC (lymphocytosis) and serology (antibodies against B. pertussis)

Management
• admit if paroxysms of cough are associated with cyanosis and/or apnea and give O₂
• supportive care
• antimicrobial therapy indicated if *B. pertussi* isolated, or symptoms present for <21 d
  ▪ use macrolide antibiotics (azithromycin, erythromycin, or clarithromycin)
• droplet isolation until 5 d of treatment and report to Public Health
• prophylaxis
  ▪ macrolide antibiotics for all household contacts
  ▪ prevention with vaccination in infants and children (Pentacel®), and booster in adolescents (Adacel®) (see *Routine Immunization*, P3)

Complications
• pressure-related from paroxysms: subconjunctival hemorrhage, rectal prolapse, hernias, epistaxis
• respiratory: sinusitis, pneumonia, aspiration, atelectasis, pneumomediastinum, pneumothorax, alveolar rupture
• neurological: seizures (~3%), encephalopathy, ICH
• mortality: ~0.3%; highest risk in infants <6 mo old

Pneumonia
• see *Pediatric Respiratory*, P90

Periorbital (Preseptal) and Orbital Cellulitis
• see *Ophthalmology*, OP10

Sexually Transmitted Disease
• see *Family Medicine*, FM45 and *Gynecology*, GY25

Sinusitis
• see *Family Medicine*, FM46
• complication of ≤10% of URTIs in children
• clinical diagnosis
• diagnostic imaging is NOT required to confirm diagnosis in children
  ▪ routine CT not recommended, but consider if suspect complications of sinusitis, persistent/recurrent disease, need for surgery
• antibiotic therapy for all children (although nearly half resolve spontaneously within 4 wk)
• complications: preseptal/orbital (preseptal/orbital cellulitis, orbital abscess, osteomyelitis, etc.), intracranial (meningitis, abscess, etc.), Pott's Puffy tumor

Urinary Tract Infection

Definition
• infection of the urinary bladder (cystitis) and/or kidneys (pyelonephritis)

Epidemiology
• overall prevalence in infants and young children presenting with fever is 7%
• <4-6 wk old: more common in boys
• >1 yr old: females have two- to four-fold higher prevalence

Etiology
• majority (>95%) have a monomicrobial cause (~70% *E. coli*)
• Gram-negative bacilli: *E. coli*, *Klebsiella*, *Proteus*, *Enterobacter*, *Pseudomonas*
• Gram-positive cocci: *S. saprophyticus*, *Enterococcus*

Risk Factors
• non-modifiable: female gender, Caucasian, previous UTIs, family history
• modifiable: urinary tract abnormalities (VUR, neurogenic bladder, obstructive uropathy, posterior urethral valve), dysfunctional voiding, repeated bladder catheterization, uncircumcised males, labial adhesions, sexually active, constipation, toilet training
History
- infants and young child: often just fever or non-specific symptoms (poor feeding, irritability, FTT, jaundice if <28 d old, vomiting)
- older child: fever, urinary symptoms (dysuria, urgency, frequency, incontinence, hematuria), abdominal and/or flank pain

Physical Exam
- infants and young child: toxic vs. non-toxic, febrile, FTT, jaundice; look for external genitalia abnormalities (phimosis, labial adhesions) and lower back signs of occult myelodysplasia (e.g., hair tufts), which may be associated with neurogenic bladder
- older child: febrile, suprapubic and/or CVA tenderness, abdominal mass (enlarged bladder or kidney); may present with short stature, FTT or HTN secondary to renal scarring from previously unrecognized or recurrent UTIs

Investigations
- sterile urine specimen
  - clean catch, catheterization, or suprapubic aspiration
  - urinalysis (leukocyte esterase, nitrites, erythrocytes, hemoglobin), microscopy (bacteria and leukocytes, erythrocytes), C&S
- diagnosis established if urinalysis suggests infection AND if ≥50,000 colony-forming units per mL of a uropathogen cultured

Management
- admit if: <2 mo old, urosepsis, persistent vomiting, inability to tolerate oral medication, moderate-severe dehydration, immunocompromised, complex urologic pathology, inadequate follow-up, failure to respond to outpatient therapy
- supportive care: maintenance of hydration and adequate pain control
- antibiotics
  - base on local antimicrobial susceptibility patterns
  - commence broad empiric therapy until results of urine C&S known, and then tailor as appropriate
  - neonates: IV ampicillin and gentamicin
  - infants and older children: oral cephalexin if outpatient; IV ampicillin and gentamicin if inpatient
  - duration 7-14 d
- imaging
  - renal and bladder U/S for all febrile infants with UTIs looking for anatomical abnormalities, hydronephrosis, abscess
  - VCUG not recommended after 1st febrile UTI unless U/S reveals hydronephrosis, obstructive uropathies or other signs suggestive of high-grade VUR
- follow-up: outpatients to return in 24-48 h if no clinical response and seek prompt medical evaluation for future febrile illnesses
- prophylaxis: generally not recommended unless higher grades of VUR

Complications
- long-term morbidity: focal renal scarring develops in 8% of patients; long-term significance unknown

Neonatology

Gestational Age and Size

Definitions
- classification by GA
  - preterm: <37 wk
  - near-term: 35-37 wk
  - term: 37-42 wk
  - post-term: >42 wk
- classification by birth weight
  - SGA: 2 SD < mean weight for GA or <10th percentile
  - AGA: within 2 SD of mean weight for GA
  - LGA: 2 SD > mean weight for GA or >90th percentile

Prophylaxis After First Febrile Urinary Tract Infection in Children? A Multicenter, Randomized Controlled, Noninferiority Trial

Pediatrics 2008;122:1064-1071

Study: Randomized, controlled, open-label, 2 armed, noninferiority trial.

Patients: 338 patients aged 2 mo-<7 yr who had a first episode of febrile UTI.

Intervention: No prophylaxis vs. prophylaxis.

Outcome: Recurrence rate of febrile UTI and rate of renal scarring.

Results: No significant difference in recurrence rate or in the rate of renal scarring between the prophylaxis and no prophylaxis group.

Dubowitz/Ballard Scores

GA can be determined after birth using Dubowitz/Ballard scores:
- Assessment at delivery of physical maturity (e.g., plantar creases, lanugo, ear maturation) and neuromuscular maturity (e.g., posture, arm recoil) translates into a score from -10 to +50
- Higher score means greater maturity (increased GA)
  - -10 = 20 wk; +50 = 44 wk
  - Ideal = 35-40, which corresponds to GA 38-40 wk
- Only accurate ± 2 wk

### Routine Neonatal Care

1. erythromycin ointment: applied to both eyes for prophylaxis of ophthalmia neonatorum
2. vitamin K IM: prophylaxis against HDNB
3. newborn screening tests
   - metabolic disorders (amino acid disorders, organic acid disorders, fatty acid oxidation defects, biotinidase deficiency, galactosemia)
   - blood disorders (SCD, other hemoglobinopathies)
   - endocrine disorders (CAH, congenital hypothyroidism)
   - others (CF, SCID)
   - congenital hearing loss
4. if mother Rh negative: send cord blood for blood group and direct antiglobulin test
5. if mother hepatitis B surface antigen positive: HBIG and start hepatitis B vaccine series

### Neonatal Resuscitation

- assess Apgar score at 1 and 5 min
- if <7 at 5 min then reassess q5min, until >7
- do not wait to assign Apgar score before initiating resuscitation

| Table 27. Apgar Score |
|-----------------------|---------------------|--------------------------|
| **Sign**              | 0                   | 1                        | 2                        |
| Heart Rate            | Absent              | <100/min                 | >100/min                 |
| Respiratory Effort    | Absent              | Slow, irregular          | Good, crying             |
| Irritability          | No response         | Grimize                  | Cough/cry                |
| Tone                  | Limp                | Some flexion of extremities | Active motion          |
| Color                 | Blue, pale          | Body pink, extremities blue (acrocyanosis) | Completely pink     |
Initial Resuscitation

- anticipation: know maternal history, history of pregnancy, labor, and delivery
- steps to take for all infants (before ABCs)
  - warm (radiant heater, warm towels) and dry the newborn (remove wet towels)
  - position and clear airway (“sniffing” position)
  - stimulate infant: rub lower back gently or flick soles of feet EXCEPT if meconium present (in which case tracheal suction first)
  - assess breathing and heart rate
- Airway
  - if meconium is present and
    - baby is vigorous (strong respiratory effort, good muscle tone, HR >100): no further resuscitative interventions required
    - baby is not vigorous: intubate and suction trachea while monitoring vital signs; if prolonged or unsuccessful intubation, attempt bag mask ventilation
  - if no meconium and suction required, suction mouth first and then nose
- Breathing
  - if HR <100 or apneic, apply PPV
  - PPV at rate of 40-60/min with enough pressure to see visible chest expansion and note increase in HR
  - monitor preductal SpO₂
  - if PPV not effective (no increase in HR, no chest rise, low SpO₂), incorporate corrective actions
- Circulation
  - if HR <60 after 30 s of effective ventilation, start chest compressions (“60 or less, compress”)
  - should provide 100% oxygen as soon as chest compressions are required
  - chest compressions at lower 1/3 of the sternum and 1/3 of the AP depth at a rate of 120 events per min (3 compressions:1 ventilation = 120 compressions/min:40 breaths/min)

Corrective Actions for PPV in Neonatal Resuscitation

MR SOPA
- Mask readjustment
- Reposition airway
- Suction mouth and nose
- Open mouth
- Pressure increase
- Alternative airway

Approach to the Depressed Newborn

- a depressed newborn lacks one or more of the following characteristics of a normal newborn
  - pulse >100 bpm
  - cries when stimulated
  - actively moves all extremities
  - has a good strong cry
- approximately 10% of newborn babies require assistance with breathing after delivery

Diagnosis
- vital signs
- detailed maternal history: include prenatal care, illnesses, use of drugs, labor, previous high risk pregnancies, infections during pregnancy, current infections, duration of ruptured membranes, blood type and Rh status, amniotic fluid status, GA, meconium, Apgar scores
- clinical findings (observe for signs of respiratory distress such as cyanosis, tachypnea, retractions, grunting, temperature instability)
- laboratory results (CBC, ABG, blood type, glucose)
- transillumination of chest to evaluate for pneumothorax
- CXR

Management
- ABCs
- intubation and suction if meconium present
- apply tactile stimulation if no meconium
- provide PPV if apneic or HR <100 bpm
- monitor SpO₂ and HR (if <60 bpm, start chest compressions)
- provide ventilatory support and treat the underlying cause

Common Conditions of Neonates

Apnea

Definition
- “periodic breathing”: normal respiratory pattern seen in newborns in which periods of rapid respiration are alternated with pauses lasting 5-10 s
- “apnea”: absence of respiratory gas flow for >20 s (or less if associated with bradycardia or desaturation) – 3 types
  - central: no chest wall movement, no signs of obstruction
  - obstructive: chest wall movement continues against obstructed upper airway, no airflow
  - mixed: combination of central and obstructive apnea

Differential Diagnosis
- in term infants, apnea requires full workup as it can be associated with sepsis
- other causes
  - CNS
  - apnea of prematurity (<34 wk): combination of CNS immaturity and obstructive apnea; resolves by 36 wk GA; diagnosis of exclusion
  - seizures
  - ICH
  - hypoxic injury
infectious: sepsis, meningitis, NEC
GI: GERD, aspiration with feeding
metabolic: hypoglycemia, hyponatremia, hypocalcemia, inborn error of metabolism
cardiovascular: anemia, hypovolemia, PDA, heart failure
medications: morphine

Management
- O2, ventilatory support, maintain normal blood gases
- tactile stimulation
- correct underlying cause
- medications: methylxanthines (caffeine) stimulate the CNS and diaphragm and are used for apnea of prematurity (not in term infants)

Bleeding Disorders in Neonates

Clinical Presentation
- oozing from the umbilical stump, excessive bleeding from peripheral venipuncture/heel stick sites/IV sites, large caput succedaneum, cephalohematoma (in absence of significant birth trauma), subgaleal hemorrhage and prolonged bleeding following circumcision

Etiology
- 4 major categories
  - increased platelet destruction: maternal ITP or SLE, infection/sepsis, DIC, neonatal alloimmune thrombocytopenia, autoimmune thrombocytopenia
  - decreased platelet production/function: pancytopenia, bone marrow replacement, Fanconi anemia, Trisomy 13 and 18
  - metabolic: congenital thyrotoxicosis, inborn error of metabolism
  - coagulation factor deficiencies (see Hematology, H29): hemophilia A/B, HDNB

NEONATAL ALLOIMMUNE THROMBOCYTOPENIA

Epidemiology
- 1 per 4,000-5,000 live births

Pathophysiology
- platelet equivalent of Rh disease of the newborn
- occurs when mother is negative for HPA and fetus is positive
- development of maternal IgG antibodies against HPA antigens on fetal platelets

Clinical Presentation
- petechiae, purpura, thrombocytopenia in otherwise healthy neonate
- severe disease can lead to intracranial bleeding

Diagnosis
- maternal and paternal platelet typing and identification of platelet alloantibodies

Treatment
- IVIg to mother prenatally starts in second trimester ± steroids ± fetal platelet transfusions
- treat neonate with IVIg
- if transfusion required should be with washed maternal platelets or donor HPA negative platelets

AUTOIMMUNE THROMBOCYTOPENIA

Pathophysiology
- caused by antiplatelet antibodies from maternal ITP or SLE
- passive transfer of antibodies across placenta

Clinical Presentation
- similar presentation to neonatal alloimmune thrombocytopenia, but thrombocytopenia usually less severe

Treatment
- steroids to mother for 10-14 d prior to delivery or IVIg to mother before delivery
- treat neonate with IVIg (usually if platelets <60,000)
- transfusion of infant with maternal/donor platelets only in severe cases, as antibodies will destroy transfused platelets
HEMORRHAGIC DISEASE OF THE NEWBORN

Pathophysiology
- caused by vitamin K deficiency
- factors II, VII, IX, X are vitamin K-dependent, therefore both PT and PTT are abnormal

Etiology and Clinical Presentation
- neonates at risk of vitamin K deficiency if: vitamin K poorly transferred across the placenta; maternal use of antiepileptics; insufficient bacterial colonization of colon at birth to synthesize vitamin K; breastfed (vitamin K intake inadequate in breastfed infants)
- neonate may present with hematomas, ICH (causing apnea or seizures), internal bleeding, hematuria, bruising, prolonged bleeding (often from mucous membranes, umbilicus, circumcision, and venipunctures)

Prevention
- vitamin K IM administration at birth to all newborns

Bronchopulmonary Dysplasia

Definition
- also known as chronic lung disease
- clinically defined as O₂ requirement for >28 d plus persistent need for oxygen and/or ventilatory support at 36 wk corrected GA
- damage to developing lungs with prolonged intubation/ventilation

Investigations
- CXR findings may demonstrate decreased lung volumes, areas of atelectasis, and hyperinflation

Treatment
- no good treatments
- gradual wean from ventilator, optimize nutrition
- dexamethasone may help decrease inflammation and encourage weaning, but use of dexamethasone is associated with increased risk of adverse neurodevelopmental outcomes

Prognosis
- chronic respiratory failure may lead to pulmonary HTN, poor growth, and right-sided heart failure
- patients with bronchopulmonary dysplasia may continue to have significant impairment and deterioration in lung function late into adolescence
- some lung abnormalities may persist into adulthood including airway obstruction, airway hyper-reactivity, and emphysema
- associated with increased risk of adverse neurodevelopmental outcomes

Cyanosis

Figure 12. Approach to neonatal cyanosis
Management
• ABGs
  ▪ elevated CO₂ suggests respiratory cause
  ▪ hyperoxia test (to distinguish between cardiac and respiratory causes of cyanosis): get baseline PaO₂ in room air, then PaO₂ on 100% O₂ for 10-15 min
    • PaO₂ <150 mmHg: suggests cyanotic CHD or possible PPHN (see Pediatric Cardiology, P16)
    • PaO₂ >150 mmHg: suggests cyanosis likely due to respiratory or non-cardiac cause
  ▪ CXR: look for respiratory abnormalities (respiratory tract malformations, evidence of shunting, pulmonary infiltrates) and cardiac abnormalities (cardiomegaly, abnormalities of the great vessels)

Diaphragmatic Hernia
• see General Surgery, GS12

Definition
• developmental defect of the diaphragm with herniation of abdominal organs into thorax
• associated with pulmonary hypoplasia and PPHN

Clinical Presentation
• respiratory distress, cyanosis
• scaphoid abdomen and barrel-shaped chest
• affected side dull to percussion and breath sounds absent, may hear bowel sounds instead
• heart sounds shifted to contralateral side
• asymmetric chest movements, trachea deviated away from affected side
• may present outside of neonatal period
• often associated with other anomalies (cardiovascular, CNS, chromosomal abnormalities)
• CXR: bowel loops in thorax (usually left side), displaced mediastinum

Treatment
• immediate intubation required at birth: DO NOT bag mask ventilate because air will enter stomach and further compress lungs
• place large bore orogastric tube to decompress bowel
• initial stabilization and management of pulmonary hypoplasia and PPHN, hemodynamic support and surgery when stable

Hypoglycemia

Definition
• glucose <40 mg/dL

Etiology
• decreased carbohydrate stores: premature, SGA, RDS, maternal HTN
• endocrine: hormonal deficiencies (GH, cortisol, epinephrine), insulin excess (infant of diabetic mother, Beckwith-Wiedemann syndrome/islet cell hyperplasia), HPA axis suppression (panhypopituitarism)
• inborn errors of metabolism: fatty acid oxidation defects, galactosemia
• miscellaneous: sepsis, hypothermia, polycythemia

Clinical Findings
• signs often non-specific and subtle: lethargy, poor feeding, irritability, tremors, apnea, cyanosis, seizures

Management
• identify and monitor infants at risk (pre-feed blood glucose checks)
• begin oral feeds as soon as possible after birth and ensure regular feeds
• if significant and/or symptomatic hypoglycemia, provide glucose IV and titrate according to blood sugar levels
• if persistent hypoglycemia or no predisposing cause, send “critical blood work” during an episode of hypoglycemia: ABG, ammonia, β-hydroxybutyrate, cortisol, free fatty acids, GH, insulin, lactate, urine dipstick for ketones
**Intraventricular Hemorrhage**

**Definition**
- hemorrhage originating in the periventricular subependymal germinal matrix

**Epidemiology**
- incidence and severity inversely proportional to GA
- 50% of IVH occurs within 8 h of birth; 90% occurs by day 3

**Risk Factors**
- prematurity (<32 wk), BW <1,500 g, need for vigorous resuscitation at birth, pneumothorax, ventilated preterm infants, hemodynamic instability, RDS, coagulopathy

**Clinical Presentation**
- many infants with IVH are asymptomatic
- subtle signs: apnea, bradycardia, changes in tone or activity, altered LOC
- catastrophic presentation: bulging fontanelle, sudden drop in hematocrit, acidosis, seizures, hypotension

**Classification**
- Papile classification
- parenchymal hemorrhage may also occur in the absence of IVH
- routine head U/S screening of all preterm infants <32 wk or <1,500 g gestation throughout NICU stay
- consider MRI at term for extremely LBW infants

**Management of Acute Hemorrhage**
- supportive care to maintain blood volume and acid-base status
- avoid fluctuations in blood pressure and cerebral blood flow
- follow-up with serial imaging

**Prognosis**
- outcome depends on grade of IVH
- short-term sequelae for severe IVH: mortality, extension of bleed, posthemorrhagic hydrocephalus, posthemorrhagic infarction, cyst formation
- possible long-term major neurological sequelae: CP, cognitive deficits, motor deficits, visual and hearing impairment
- Grades I and II hemorrhages have a relatively favorable prognosis
- greatest morbidity and mortality is seen with Grade IV hemorrhage and posthemorrhagic hydrocephalus requiring ventriculoperitoneal shunt placement

**Jaundice**

**Clinical Presentation**
- jaundice is visible at serum bilirubin levels of 5 mg/dL; visual assessment is often misleading
- look at sclera, tip of nose in natural light
- jaundice more severe/prolonged (due to increased retention of bilirubin in the circulation) with: prematurity, acidosis, hypoalbuminemia, dehydration, hemolysis

**Hyperbilirubinemia**

- **Pathologic**
  - Hemolysis
  - Intrinsic Membrane
    - Spherocytosis
    - Elliptocytosis
    - Enzyme: G6PD deficiency
    - PK deficiency
    - Hemoglobin α-thalassemia
  - Extrinsic Immune
    - ABO incompatibility
    - Rh incompatibility
    - Kell, Duffy, etc.
    - Non-immune
    - Splenomegaly
    - Sepsis
    - AV malformation
  - Non-Hemolytic
    - Hematoma (cephalohematoma)
    - Polycythemia
    - Sepsis
    - Hypothyroidism
    - Gilbert syndrome
    - Crigler-Najjar
- **Physiologic**
  - Hepatic
    - Infectious Sepsis
    - Hep B, TORCH
    - Metabolic
    - Galactosemia
    - Tyrosinemia
    - α₁-antitrypsin deficiency
    - Hypothyroidism
    - CF
    - Drugs
    - TPN
    - Idiopathic neonatal hepatitis
- **Always pathologic**
  - Post-Hepatic
    - Biliary atresia
    - Choledochal cyst

**Figure 13. Approach to neonatal hyperbilirubinemia**
PHYSIOLOGIC JAUNDICE

Epidemiology
- term infants: onset 3-4 d of life, resolution by 10 d of life
- premature infants: higher peak and longer duration

Pathophysiology
- increased hematocrit and decreased RBC lifespan
- immature glucuronyl transferase enzyme system (slow conjugation of bilirubin)
- increased enterohepatic circulation

Breastfeeding Jaundice
- common; due to a lack of milk production → dehydration → exaggerated physiologic jaundice

Breast Milk Jaundice
- 1 per 200 breastfed infants
- glucuronyl transferase inhibitor found in breast milk
- onset 7 d of life, peak at 2-3 wk of life, usually resolved by 6 wk

Table 30. Risk Factors for Jaundice

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

PATHOLOGIC JAUNDICE
- all cases of conjugated hyperbilirubinemia; some cases of unconjugated hyperbilirubinemia are pathologic

Investigations
- unconjugated hyperbilirubinemia
  - hemolytic workup: CBC, reticulocyte count, blood group (mother and infant), peripheral blood smear, Coombs test
  - if baby is unwell or has fever: septic workup (CBC and differential, blood and urine cultures ± LP, CXR)
  - other: G6PD screen (especially in males), TSH
- conjugated hyperbilirubinemia must be investigated without delay
  - consider liver enzymes (AST, ALT), coagulation studies (PT, PTT), serum albumin, ammonia, TSH, TORCH screen, septic workup, galactosemia screen (erythrocyte galactose-1-phosphate uridylyltransferase levels), metabolic screen, abdominal U/S, HIDA scan, sweat chloride

TREATMENT OF UNCONJUGATED HYPERBILIRUBINEMIA
- to prevent kernicterus
- breastfeeding does not usually need to be discontinued, ensure adequate feeds and hydration
- lactation consultant support, mother to pump after feeds
- treat underlying causes (e.g. sepsis)
- phototherapy (blue-green wavelength, not UV light)
  - insoluble unconjugated bilirubin is converted to excretable form via photoisomerization
  - serum bilirubin should be monitored during and immediately after therapy (risk of rebound because photoisomerization reversible when phototherapy discontinued)

Jaundice must be investigated if:
- It occurs within 24 h of age
- Conjugated hyperbilirubinemia is present
- Unconjugated bilirubin rises rapidly or is excessive for patient’s age and weight
- Persistent jaundice lasts beyond 1-2 wk of age
contraindicated in conjugated hyperbilirubinemia: results in “bronzed” baby
side effects: skin rash, diarrhea, eye damage (eye shield used routinely for prevention), dehydration
use published guidelines and nomogram for initiation of phototherapy
exchange transfusion
indicators: high bilirubin levels as per published graphs based on age, weeks gestation
most commonly performed for hemolytic disease and G6PD deficiency
use of IV Ig in case of severe hyperbilirubinemia (DAT+) becoming evidence-based practice

KERNICTERUS

Etiology
• unconjugated bilirubin concentrations exceed albumin binding capacity and bilirubin is deposited in the brain resulting in permanent damage (typically basal ganglia or brainstem)
• incidence increases as serum bilirubin levels increase above 19.8 mg/dL.
• can occur at lower levels in presence of sepsis, meningitis, hemolysis, hypoxia, acidosis, hypothermia, hypoglycemia, and prematurity

Clinical Presentation
• up to 15% of infants have no obvious neurologic symptoms
• early stage: lethargy, hypotonia, poor feeding, emesis (bilirubin encephalopathy)
• mid stage: hypertonia, high pitched cry, opisthotonic posturing (back arching), bulging fontanelle, seizures, pulmonary hemorrhage
• late stage (first year and beyond)
  • hypotonia, delayed motor skills, extrapyramidal abnormalities (choreoathetoid CP), gaze palsy, mitral regurgitation, sensorineural hearing loss

Prevention
• exchange transfusion, IV Ig if indicated

BILIARY ATRESIA
• see General Surgery, GS63

Definition
• atresia of the extrahepatic bile ducts which leads to cholestasis and increased conjugated bilirubin after the first week of life
• progressive obliterative cholangiopathy

Epidemiology
• incidence: 1:10,000-15,000 live births
• associated anomalies in 10-35% of cases: situs inversus, congenital heart defects, polysplenia

Clinical Presentation
• dark urine, pale stool, jaundice (persisting for >2 wk), abdominal distension, hepatomegaly

Diagnosis
• conjugated hyperbilirubinemia, abdominal U/S
• HIDA scan (may be bypassed in favor of biopsy if timing of diagnosis is critical)
• liver biopsy

Treatment
• surgical drainage procedure
• hepatopancreaticoenterostomy (Kasai procedure; most successful if <8 wk of age)
• two-thirds will eventually require liver transplantation
• vitamins A, D, E, and K; diet should be enriched with medium-chain triglycerides to ensure adequate fat ingestion

Necrotizing Enterocolitis

Definition
• intestinal inflammation associated with focal or diffuse ulceration and necrosis
• primarily affecting terminal ileum and colon

Epidemiology
• affects 1-5% of preterm newborns admitted to NICU
Pathophysiology
• postulated mechanism of bowel ischemia: mucosal damage and enteral feeding → bacterial growth → bowel necrosis/gangrene/perforation

Risk Factors
• prematurity (immature defenses)
• asphyxia, shock (poor bowel perfusion)
• hyperosmolar feeds
• enteral feeding with formula (breast milk can be protective)
• sepsis

Clinical Presentation
• usually presents at 2-3 wk of age
• distended abdomen
• increased amount of gastric aspirate/vomitus with bile staining
• frank or occult blood in stool
• feeding intolerance
• diminished bowel sounds
• signs of bowel perforation (sepsis, shock, peritonitis, DIC)

Investigations
• AXR: pneumonitis intestinalis (intramural air is a hallmark of NEC), free air, fixed loops, ileus, thickened bowel wall, portal venous gas
• CBC, ABG, lactate, blood culture, electrolytes
• high or low WBC, low platelets, hyponatremia, acidosis, hypoxia, hypercapnea

Treatment
• NPO (7-10 d), vigorous IV fluid resuscitation, decompression with NG tube, supportive therapy
• TPN
• antibiotics (usually ampicillin, gentamicin ± metronidazole if risk of perforation x 7-10 d)
• serial AXRs detect early perforation (40% mortality in perforated NEC)
• peritoneal drain/surgery if perforation
• surgical resection of necrotic bowel and surgery for complications (e.g. perforation, strictures)

Persistent Pulmonary Hypertension of the Newborn

Epidemiology
• incidence 1.9 per 1,000 live births

Clinical Presentation
• usually presents within 12 h of birth with severe hypoxemia/cyanosis; may have only mild respiratory distress

Pathophysiology
• persistence of fetal circulation as a result of persistent elevation of pulmonary vascular resistance
• R → L shunt through PDA, foramen ovale → decreased pulmonary blood flow and hypoxemia → further pulmonary vasoconstriction

Risk Factors
• secondary PPHN: asphyxia, MAS, RDS, sepsis, pneumonia, structural abnormalities (e.g. diaphragmatic hernia, pulmonary hypoplasia)
• primary PPHN occurs in absence of risk factors
• more common in term or post-term infants

Investigations
• measure pre- and post-ductal oxygen levels
• hyperoxia test to exclude CHD
• ECG (RV strain)
• Echo reveals increased pulmonary arterial pressure and a R → L shunt across PDA and patent foramen ovale; also used to rule out other cardiac defects

Treatment
• maintain good oxygenation (SaO2 >95%) in at-risk infants
• O2 given early and tapered slowly, minimize stress and metabolic demands, maintain normal blood gases, circulatory support
• mechanical ventilation, high frequency oscillation in a sedated muscle-relaxed infant
• nitric oxide, surfactant
• extracorporeal membrane oxygenation used in some centers when other therapy fails
Respiratory Distress in the Newborn

Clinical Presentation
- tachypnea: RR >60/min; tachycardia: HR >160/min
- grunting, subcostal/intercostal indrawing, nasal flaring
- duskmness, central cyanosis
- decreased air entry, crackles on auscultation

Differential Diagnosis of Respiratory Distress
- pulmonary: RDS, TTN, MAS, pleural effusion, pneumothorax, congenital lung malformations
- infectious: sepsis, pneumonia
- cardiac: CHD (cyanotic, acyanotic), PPHN
- hematologic: blood loss, polycythemia
- anatomic: TEF, congenital diaphragmatic hernia, mucous or meconium plug, upper airway obstruction (see Otolaryngology, OT44)
- metabolic: hypoglycemia, inborn errors of metabolism
- neurologic: CNS damage (trauma, hemorrhage), drug withdrawal syndromes

Investigations
- CXR, ABG (or venous blood gas from umbilical venous line)
- CBC, blood cultures, blood glucose
- Echo, ECG if indicated

Table 32. Distinguishing Features of RDS, TTN, MAS

PNEUMONIA
- see Pediatric Respirology, P90
- consider in infants with prolonged or premature rupture of membranes, maternal fever, or if mother is GBS positive
- suspect if infant exhibits respiratory distress, temperature instability, or WBC is low, elevated, or left-shifted
- symptoms may be non-specific
- CXR: hazy lung and/or distinct infiltrates (may be difficult to differentiate from RDS)

Retinopathy of Prematurity
- see Ophthalmology, OP41

Sepsis in the Neonate

Signs of Sepsis
- no reliable absolute indicator of occult bacteremia in infants <3 mo, most specific result has been WBC <5
- temperature instability (hypo/hyperthermia)
- respiratory distress, cyanosis, apnea
- tachycardia/bradycardia
- lethargy, irritability
- poor feeding, vomiting, abdominal distension, diarrhea
- hypotonia, seizures, lethargy
- jaundice, hepatomegaly, petechiae, purpura

Chronic Perinatal Infections
CHEAP TORCHES
- Chicken pox/shingles
- Hepatitis B
- Epstein-Barr virus

<td>Lesions 1-2 mm firm white pearly papules on nasal bridge, cheeks, and palate; self-resolving</td>
</tr>
<tr>
<td>Pustular Melanosis</td>
<td>Brown macular base with pustules, seen more commonly in African American infants; may be present at birth</td>
</tr>
<tr>
<td>Nevus Simplex (Salmon Patch)</td>
<td>Transient macular vascular malformation of the eyelids and/or neck (“Angel Kiss” or “Stork Bite”); most lesions disappear by 1 yr of life</td>
</tr>
<tr>
<td>Neonatal Acne</td>
<td>Inflammatory papules and pustules mainly on face; self-resolving</td>
</tr>
</tbody>
</table>

### Fluids and Electrolytes

#### Approach to Infant/Child with Dehydration

**Etiology**
- decreased intake: poor oral intake during acute illness, breastfeeding difficulties, eating disorders
- increased losses: common sites include GI tract (diarrhea, vomiting, bleeding), skin/mucous membranes (fever, burns, hemorrhage, stomatitis), urine (osmotic diuresis [e.g. hyperglycemia, DKA], diuretic therapy, DI, post-obstructive/post ATN recovery diuresis), and respiratory tract (tachypnea, bronchiolitis, pneumonia)

**Management**
- if suspect dehydration based on history (acute illness, decreased number of wet diapers, lethargy, changes in mental status, increased thirst, etc.), you must:

1) **Determine degree of extracellular volume contraction**

<table>
<thead>
<tr>
<th>Mild</th>
<th>Moderate</th>
<th>Severe</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;2 yr</td>
<td>5%*</td>
<td>10%*</td>
</tr>
<tr>
<td>&gt;2 yr</td>
<td>3%*</td>
<td>6%*</td>
</tr>
</tbody>
</table>

- Pulse
- Blood Pressure
- Urine Output
- Oral Mucosa
- Anterior Fontanelle
- Eyes
- Skin Turgor
- Capillary Refill

* Note that percentages refer to percent loss of pre-illness body weight

2) **Determine the likely electrolyte disturbance**
- dependent on etiology of dehydration and type of fluid loss (isotonic vs. hypertonic vs. hypotonic)
Table 36. Electrolyte Content of Various Bodily Fluids

<table>
<thead>
<tr>

</tbody>
</table>

- for moderate and severe dehydration, initial investigations should include urinalysis and blood work examining electrolyte (Na⁺, K⁺, Cl⁻), glucose, and acid-base (blood pH, pCO₂, HCO₃⁻ disturbances), and impaired renal function (creatinine, BUN)

3) Determine if the child requires PO or IV rehydration
- dehydrated child must receive adequate fluid management, including replacement of ongoing losses and maintenance fluids
- initial management using ORT advantages: ↓ cost, no IV needed, incidence of iatrogenic hyper/hyponatremia, parental involvement in therapy
- indications for IV rehydration therapy: severe dehydration requiring close monitoring and frequent assessment of electrolytes, inability to tolerate ORT (e.g. vomiting, alteration in mental status, ileus, monosaccharide malabsorption, etc.), inability to provide ORT, failure of ORT in providing adequate rehydration (e.g. persistent diarrhea or vomiting)

4) Return the child to a normal volume and electrolyte status by replacing current deficits and ongoing losses

5) Provide the appropriate fluid and electrolyte maintenance daily requirements

Table 37. Maintenance Fluid Requirements

<table>
<thead>
<tr>
<th>Body Weight</th>
<th>100:50:20 Rule (24 h maintenance fluids)</th>
<th>4:2:1 Rule (hourly rate of maintenance fluids)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-10 kg</td>
<td>100 cc/kg/d</td>
<td>4 cc/kg/h</td>
</tr>
<tr>
<td>11-20 kg</td>
<td>50 cc/kg/d</td>
<td>2 cc/kg/h</td>
</tr>
<tr>
<td>&gt;20 kg</td>
<td>20 cc/kg/d</td>
<td>1 cc/kg/h</td>
</tr>
</tbody>
</table>

- types of fluids used: NS, RL, half NS (0.45% NaCl), 0.2% NS (for neonates only), D5W, and D10W (for neonates only); add potassium chloride if hypokalemic
- in children, all maintenance fluids should have a dextrose component due to their higher risk of hypoglycemia, especially if they are NPO
- common IV fluid combinations used in pediatrics
  ▪ first month of life: D5W/0.2 NS + KCl 20 mEq/L (only add KCl if voiding well)
  ▪ children: D5W/NS + KCl 20 mEq/L or D5W/0.45 NS + KCl 20 mEq/L
  ▪ NS: as bolus to restore circulation in dehydrated children (remains almost entirely distributed in intravascular space)

Special Consideration – SIADH
Clinical Signs: hyponatremia and excretion of concentrated urine
Renal Failure: certain medications (e.g. morphine), post-operative, pain, N/V, pulmonary disease (e.g. pneumonia), CNS disease (e.g. meningitis)
Caution: acute hyponatremia is associated with rapid administration of hypotonic IV, this can lead to cerebral edema and herniation
6) Continue to monitor fluid and electrolyte status

- accurate monitoring of daily fluid intake (PO and IV) and ongoing losses (urine output, diarrhea, emesis, drains)
- if child receiving >50% of maintenance fluids through IV, serum electrolyte values should be monitored daily and therapy adjusted accordingly
- avoid iatrogenic hyper/hyponatremia, keep the possibility of SIADH in mind

**Nephrology**

### Common Pediatric Renal Diseases

### Hemolytic Uremic Syndrome

#### Definition

- simultaneous occurrence of the triad of 1) non-immune microangiopathic hemolytic anemia, 2) thrombocytopenia, and 3) acute renal injury

#### Epidemiology

- annual incidence of 1-2 per 100,000 in Canada
- most common cause of acute renal failure in children

#### Etiology

- diarrhea positive HUS: 90% of pediatric HUS from *E. coli* O157:H7, shiga toxin, or verotoxin
- diarrhea negative HUS: other bacteria, viruses, familial, drugs, familial/genetic

#### Pathophysiology

- toxin binds, invades, and destroys colonic epithelial cells, causing bloody diarrhea
- toxin enters the systemic circulation, attaches, and injures endothelial cells (especially in kidney), causing a release of endothelial products (e.g. von Willebrand factor, platelet aggregating factor)
- platelet/fibrin thrombi form in multiple organ systems (e.g. kidney, pancreas, brain, etc.) resulting in thrombocytopenia
- RBCs are forced through occluded vessels, resulting in fragmented RBCs (schistocytes) that are removed by the reticuloendothelial system (hemolytic anemia)
**History and Physical Exam**
- history: initial presentation of abdominal pain and diarrhea, followed by bloody diarrhea; within 5-7 d begins to show signs of anemia, thrombocytopenia, and renal insufficiency
- physical exam: pallor, jaundice (hemolysis), edema, petechiae, HTN

**Investigations**
- CBC (anemia, thrombocytopenia), blood smear (schistocytes), electrolytes, renal function, urinalysis (microscopic hematuria), stool cultures, and verotoxin/shigella toxin assay

**Management**
- mainly supportive: nutrition, hydration, ventilation (if necessary), blood transfusion for symptomatic anemia
- monitor electrolytes and renal function: dialysis if electrolyte abnormality (hyperkalemia) cannot be corrected, fluid overload, or uremia
- steroids are not helpful
- antibiotics are contraindicated because death of bacteria leads to increased toxin release and worse clinical course

**Prognosis**
- 5-10% mortality, 10-30% long-term renal damage (HTN, proteinuria, decreased renal function)

---

## Nephritic Syndrome

**Definition**
- acute or chronic syndrome affecting the kidney, characterized by glomerular injury and inflammation, and defined by hematuria (>5 RBCs per high-powered microscope field) and the presence of dysmorphic RBCs and RBC casts on urinalysis
- often accompanied by at least one of proteinuria (<50 mg/kg/d), edema, HTN, azotemia, and oliguria

**Epidemiology**
- highest incidence in children aged 5-15 yr old

**Etiology**
- humoral immune response to a variety of etiologic agents → immunoglobulin deposition → complement activation, leukocyte recruitment, release of growth factors/cytokines → glomerular inflammation and injury → porous podocytes → hematuria + RBC casts ± proteinuria
- HTN secondary to fluid retention and increased renin secretion by ischemic kidneys

**Table 39. Major Causes of Nephritic Syndrome**

<td></td>
<td>Abscess or shunt nephritis</td>
<td>Granulomatosis with polyangiitis</td>
</tr>
<tr>
<td></td>
<td>Cryoglobulinemia</td>
<td>Goodpasture’s syndrome</td>
</tr>
</tbody>
</table>

**Risk Factors**
- see [Major Causes of Nephritic Syndrome](#), above

**History and Physical Exam**
- often asymptomatic; some overlap in clinical findings for nephritic and nephrotic syndrome
- gross hematuria, mild-moderate edema, oliguria, HTN
- signs and symptoms suggestive of underlying systemic causes (e.g. fever, arthralgias, rash, dyspnea, pulmonary hemorrhage)

**Investigations**
- urine
  - dipstick (hematuria, 0 to 2+ proteinuria) and microscopy (>5 RBCs per high-powered microscope field, acanthocytes, RBC casts)
  - first morning urine protein/creatinine ratio (<200 mg/mmol)
• blood work
  ▪ impaired renal function (↑ Cr and BUN) resulting in ↓ pH and electrolyte abnormalities (hyperkalemia, hyperphosphatemia, hypocalcemia)
  ▪ mild anemia on CBC (secondary to hematuria)
  ▪ hypoalbuminemia (secondary to proteinuria)
  ▪ appropriate investigations to determine etiology: C3/C4 levels, serologic testing for recent streptococcal infection (ASOT, anti-hyaluronidase, anti-streptokinase, anti-NAD, anti-DNAse B), ANA, anti-DNA antibodies, ANCA, serum IgA levels, anti-GBM antibodies
  ▪ renal biopsy should be considered only in the presence of acute renal failure, no evidence of streptococcal infection, normal and C3/C4

Management
• treat underlying cause
• symptomatic
  ▪ renal insufficiency: supportive (dialysis if necessary), proper hydration
  ▪ HTN: salt and fluid restriction (but not at expense of renal function), ACE inhibitors or ARBs for chronic persistent HTN (not acute cases because ACE inhibitors or ARBs may decrease GFR further)
  ▪ edema: salt and fluid restriction, possibly diuretics (avoid if significant intravascular depletion)
  ▪ corticosteroids if indicated: IgA nephropathy, lupus nephritis, etc.

Prognosis
• dependent on underlying etiology
• complications include HTN, heart failure, pulmonary edema, chronic kidney injury (requiring renal transplant)

Nephrotic Syndrome

Definition
• clinical syndrome affecting the kidney, characterized by significant proteinuria, peripheral edema, hypoalbuminemia, and hyperlipidemia

Epidemiology
• highest incidence in children 2-6 yr old, M>F

Etiology
• primary (idiopathic): nephrotic syndrome in the absence of systemic disease (most common cause in pediatrics)
  ▪ glomerular inflammation ABSENT on renal biopsy: MCD (85%), focal segmental glomerular sclerosis
  ▪ glomerular inflammation PRESENT on renal biopsy: membranoproliferative GN, IgA nephropathy
• secondary: nephrotic syndrome associated with systemic disease or due to another process causing glomerular injury (<10% in pediatrics)
  ▪ autoimmune: SLE, DM, rheumatoid arthritis
  ▪ genetic: sickle cell disease, Alport syndrome
  ▪ infections: hepatitis B/C, post-streptococcal, infective endocarditis, HUS, HIV
  ▪ malignancies: leukemia, lymphoma
  ▪ medications: captopril, penicillamine, NSAIDs, antiepileptics
  ▪ vasculitides: HSP, granulomatosis with polyangiitis
• congenital: congenital nephropathy of the Finnish type, Denys-Drash syndrome, etc.

Risk Factors
• family history, certain systemic illnesses and medications (as per Etiology)

History and Physical Exam
• non-specific (e.g. irritability, malaise, fatigue, anorexia, diarrhea)
• edema
  ▪ often first sign; detectable when fluid retention exceeds 3-5% of body weight
  ▪ starts periorbital and often pretibial → edematous areas are white, soft, and pitting
  ▪ gravity dependent: periorbital edema ↓ and pretibial edema ↑ over the day
  ▪ anasarca may develop (i.e. marked periorbital and peripheral edema, ascites, pleural effusions, scrotal/labial edema)
• decrease in effective circulating volume (e.g. tachycardia, HTN, oliguria, etc.)
• foamy urine is a possible sign of proteinuria
Investigations

- urine
  - urine dipstick (3 to 4+ proteinuria, microscopic hematuria) and microscopy (oval fat bodies, hyaline casts)
  - first morning urine protein/creatinine ratio (>200 mg/mmol)

- blood work
  - diagnostic: hypoalbuminemia (<25 g/L), hyperlipidemia/hypercholesterolemia (total cholesterol >5 mmol/L)
  - secondary: electrolytes (hypocalcemia, hyperkalemia, hyponatremia), renal function (↑ BUN and Cr), coagulation profile (↑ PTT)
  - appropriate investigations to rule out secondary causes: CBC, blood smear, C3/C4, ANA, hepatitis B/C titers, ASOT, HIV serology, etc.

- consider renal biopsy if: HTN, gross hematuria, ↑ renal function, low serum C3/C4, no response to steroids after 4 wk of therapy, frequent relapses (>2 in 6 mo), presentation before first year of life (high likelihood of congenital nephrotic syndrome), presentation ≥12 yr (rule out more serious renal pathology than MCD)

Management

- MCD: oral prednisone 2 mg/kg/d (or equivalent) for up to 12 wk → varicella status should be known before starting
- consider cytotoxic agents, immunomodulators, or high-dose pulse corticosteroid if steroid resistant
- symptomatic
  - edema: salt and fluid restriction, possibly diuretic (avoid if significant intravascular depletion); furosemide + albumin for anasarca
  - hyperlipidemia: generally resolves with remission; limit dietary fat intake; consider statin therapy if persistently nephrotic
  - hypoalbuminemia: IV albumin and furosemide not routinely given; consider if refractory edema
  - abnormal BP: control BP; fluid resuscitation if severe intravascular depletion; ACEI or ARBs for persistent HTN
- diet: no added salt; monitor caloric intake and supplement with Ca²⁺ and Vit D if on corticosteroids
- daily weights and BP to assess therapeutic progress
- secondary infections: treat with appropriate antimicrobials; antibiotic prophylaxis not recommended; pneumococcal vaccine at diagnosis and varicella vaccine after remission; varicella Ig + acyclovir if exposed while on corticosteroids
- secondary hypercoagulability: mobilize, avoid hemoconcentration due to hypovolemia, prompt sepsis treatment; heparin if thrombi occur

Prognosis

- generally good: 80% of children responsive to corticosteroids
- up to 2/3 experience relapse, often multiple times; sustained remission with normal kidney function usually by adolescence
- complications: ↑ risk of infections (spontaneous peritonitis, cellulitis, sepsis); hypercoagulability due to decreased intravascular volume and antithrombin III depletion (PE, renal vein thrombosis); intravascular volume depletion, leading to hypotension, shock, renal failure; side effects of drugs

Hypertension in Childhood

Definition

- HTN: sBP and/or dBP ≥95th percentile for sex, age, and height on ≥3 occasions
- pre-HTN: sBP and/or dBP ≥90th percentile but <95th percentile OR BP ≥120/80 irrespective of age, gender, and height

Adapted from: Update on the 1987 Task Force Report on High Blood Pressure in Children and Adolescents Working Group Report from the National High Blood Pressure Education Program
Epidemiology
- increasing prevalence of both HTN and pre-HTN over the last 25+ yr
- prevalence: 3-5% for HTN, 7-10% for pre-HTN; M>F

Etiology
- primary HTN
  - diagnosis of exclusion
  - most common in older children (≥10 yr), especially if positive family history, overweight, and only mild HTN
  - responsible for ~90% of cases of HTN in adolescents, rarely in young children
- secondary HTN
  - identifiable cause of HTN (most likely etiology depends on age)
  - responsible for majority of childhood HTN
  - always consider white coat HTN for all ages

Table 41. Etiology of Secondary HTN by Age Group

*Note: may include hyperthyroidism, hyperparathyroidism, Cushing's syndrome, primary hyperaldosteronism/Conn's syndrome, pheochromocytoma

Risk Factors
- primary HTN: male gender, positive family history, metabolic syndrome, obstructive sleep apnea, African American, prematurity/LBW
- secondary HTN: history of renal disease, abdominal trauma, family history of autoimmune diseases, umbilical artery catheterization

History
- often asymptomatic, but can include FTT, fatigue, epistaxis
- symptoms of hypertensive emergency
  - neurologic: headache, seizures, focal complaints, change in mental status, visual disturbances
  - cardiovascular: symptoms of MI or heart failure (chest pain, palpitations, cough, SOB)
- symptoms of secondary HTN: guided by etiology; ask about medications and recreational drugs (current and past)

Physical Exam
- BP measurement (make sure correct cuff size is used), plot on growth chart, BMI
- look for signs of hypertensive emergency (e.g. full neurologic exam, ophthalmoscopy, precordial exam, peripheral pulses, perfusion status)
- look for signs of secondary HTN

Investigations
- laboratory
  - urine dipstick for hematuria and/or proteinuria (renal disease), urine catecholamines (pheochromocytoma, neuroblastoma)
  - blood work: renal function tests (electrolytes, Cr, BUN), consider renin and aldosterone levels (RAS, Conn's syndrome, Wilms' tumor)
  - other specific hormones if indicated on history and physical
- imaging: Echo (coarctation, heart function), abdominal U/S (RAS, abdominal mass), renal radionucleide imaging (renal scarring)
- other: ocular exam

Management
- treat underlying cause
- non-pharmacologic: modify concurrent cardiovascular risk factors (weight reduction, exercise, salt restriction, smoking cessation)
- pharmacologic: gradual lowering of BP using thiazide diuretics; no antihypertensives have been formally studied in children; if hypertensive emergencies use hydralazine, labetalol, sodium nitroprusside

Pediatric BP Calculation
\[ sBP = \text{age} \times 2 + 90 \]
\[ dBP = \frac{2}{3} \times sBP \]
• management of end-organ damage (e.g. retinopathy, LVH)
• consider referral to specialist

Prognosis
• end-organ damage (similar to adults) including LVH, CHF, cerebrovascular insults, renal disease, retinopathy

Neurology

Seizure Disorders

• see Neurology, N16

Differential Diagnosis of Seizures in Children
• benign febrile seizure
• CNS: infection, tumor, HIE, trauma, hemorrhage
• metabolic: hypoglycemia, hypocalcemia, hyponatremia
• idiopathic epilepsy and epileptic syndromes
• others: neurocutaneous syndromes, AVM, drug ingestions/withdrawal
• seizure mimics

Investigations
• lab tests: CBC, electrolytes, calcium, magnesium, glucose
• toxicology screen if indicated
• EEG
• CT/MRI, if indicated (focal neurological deficit or has not returned to baseline several hours after seizure)
• consider LP if first-time non-febrile seizure (not indicated for determining recurrence risk of benign febrile seizures or to determine seizure type or epileptic syndrome)

CHILDHOOD EPILEPTIC SYNDROMES

Infantile Spasms
• brief, repeated symmetric contractions of neck, trunk, extremities (flexion and extension) lasting 10–30 s
• occur in clusters; often associated with developmental delay; onset 4–8 mo
• 20% unknown etiology (usually good response to treatment); 80% due to metabolic or developmental abnormalities, encephalopathies, or are associated with neurocutaneous syndromes (usually poor response to treatment)
• can develop into West syndrome (infantile spasms, psychomotor developmental arrest, and hyperarrhythmia) or Lennox-Gastaut (see below)
• typical EEG: hyperarrhythmia (high voltage slow waves, spikes and polyspikes, background disorganization)
• management: ACTH, vigabatrin, benzodiazepines

Lennox-Gastaut
• characterized by triad of 1) multiple seizure types, 2) diffuse cognitive dysfunction, and 3) slow generalized spike and slow wave EEG
• onset commonly 3–5 yr of age
• seen with underlying encephalopathy and brain malformations
• management: valproic acid, benzodiazepines, and ketogenic diet; however, response often poor

Juvenile Myoclonic Epilepsy (Janz Syndrome)
• myoclonus particularly in morning; frequently presents as generalized tonic-clonic seizures
• adolescent onset (12-16 yr of age); autosomal dominant with variable penetrance
• typical EEG: 3.5-6 Hz irregular spike and wave, increased with photic stimulation
• management: lifelong treatment (valproic acid); excellent prognosis

Childhood Absence Epilepsy
• multiple daily absence seizures lasting <30 s without post-ictal state that may resolve spontaneously or become generalized in adolescence
• peak age of onset 6-7 yr, F>M, strong genetic predisposition
• typical EEG: 3 Hz spike and wave
• management: valproic acid or ethosuximide

Ketogenic Diet and Other Dietary Treatments for Epilepsy

Cochrane DB Syst Rev 2012;3:CD001903

Study: Systematic review of all studies of ketogenic and related diets. Included the review of 4 RCTs, 6 prospective studies, and 5 retrospective studies.

Population: Adults and children with diagnosed epilepsy of any type.

Intervention: Ketogenic diet, control (placebo diet, any treatment with known antiepileptic properties).

Main Outcome Measure: Seizure control at 3, 6, 12 mo.

Results: Studies showed a response rate of at least 30-50% seizure reduction at 3 mo. This response was maintained for up to a year. A range of side effects were reported. The most frequent were gastrointestinal effects (30%).

Conclusion: The ketogenic diet is a valid option for people with medically-intractable epilepsy.
Benign Focal Epilepsy of Childhood with Rolandic/Centrotemporal Spikes
• focal motor seizures involving tongue, mouth, face, upper extremity usually occurring in sleep-wake transition states; remains conscious, but aphasic post-ictally
• onset peaks at 5-10 yr of age; 16% of all non-febrile seizures; remits spontaneously in adolescence without sequelae
• typical EEG: repetitive spikes in centrotemporal area with normal background
• management: frequent seizures controlled by carbamazepine, no medication if infrequent seizures

General Approach to Treatment
• education for patient and parents including education and precautions in daily life (e.g. buddy system, showers instead of baths)
• medication
  - initiate: treatment with drug appropriate to seizure type; often if >2 unprovoked afebrile seizures within 6-12 mo
  - optimize: start with one drug and increase dosage until seizures controlled
  - if no effect, switch over to another before adding a second antiepileptic drug
  - continue antiepileptic drug therapy until patient free of seizures for >2 yr, then wean over 4-6 mo
• ketogenic diet (high fat diet): used in patients who do not respond to polytherapy or who do not wish to take medication (valproic acid contraindicated in conjunction with ketogenic diet because may increase hepatotoxicity)
• legal obligation to report to Ministry of Transportation if patient wishes to drive

Generalized and Partial Seizures
• see Neurology, N16

Febrile Seizures

Epidemiology
• most common cause of seizure in children (3-5% of children)
• M>F; age 6 mo-6 yr

Clinical Presentation
• often with associated illness or fever and family history
• no evidence of CNS infection/inflammation before or after seizure; no history of non-febrile seizures

Table 42. Comparison of Typical and Atypical Febrile Seizures

<table>
<thead>
<tr>
<th>Simple/Typical (70-80%)</th>
<th>Complex/Atypical (20-30%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>All of the following:</td>
<td>At least one of the following:</td>
</tr>
<tr>
<td>• Duration &lt;15 min (95% &lt; 5 min)</td>
<td>• Duration &gt;15 min</td>
</tr>
<tr>
<td>• Generalized tonic-clonic</td>
<td>• Focal onset or focal features during seizure</td>
</tr>
<tr>
<td>• No recurrence in 24 h period</td>
<td>• Recurrent seizures (&gt;1 in 24 h period)</td>
</tr>
<tr>
<td>• No neurological impairment or developmental delay before or after seizure</td>
<td>• Previous neurological impairment or neurological deficit after seizure</td>
</tr>
</tbody>
</table>

Workup
• history: determine focus of fever, description of seizure, medications, trauma history, development, family history
• physical exam: LOC, signs of meningitis, neurological exam, head circumference, focus of infection
• septic workup including LP if suspecting meningitis (strongly consider if child <12 mo; consider if child is 12-18 mo; only if meningial sign present if child >18 mo)
• if typical febrile seizure, investigations only for determining focus of fever
• EEG/CT/MRI brain not warranted unless atypical febrile seizure or abnormal neurologic findings

Management
• counsel and reassure patient and parents
  - febrile seizures do not cause brain damage
  - very small risk of developing epilepsy: 9% in child with multiple risk factors; 2% in child with typical febrile seizures compared to 1% in general population
  - 33% chance of recurrence (mostly within 1 yr of first seizure and in children <1 yr old)
  - antipyretics and fluids for comfort (though neither prevent seizure)
• prophylaxis with antiepileptic drugs not recommended
• if high risk for recurrent or prolonged seizures, have rectal or sublingual lorazepam at home
• treat underlying cause of fever

### Recurrent Headache

- see [Neurology, N43](#)

**Differential Diagnosis**
- primary headache: tension, migraine, cluster
- secondary headache: see [Neurology, N43](#)

**General Assessment**
- if unremarkable history and neurological and general physical exam is negative, most likely diagnosis is migraine or tension headache
- inquire about level of disability, academic performance, after-school activities

### Hypotonia

- decreased resistance to passive movements – “floppy baby”

**Differential Diagnosis**

- central: chromosomal (DS, Prader-Willi, Fragile X syndrome), metabolic (hypoglycemia, kernicterus), perinatal problems (asphyxia, ICH), endocrine (hypothyroidism, hypopituitarism), systemic illness (TORCH infection, sepsis, dehydration), CNS malformations, dysmorphic syndromes
- peripheral: motor neuron (spinal muscular atrophy, polio), peripheral nerve (Charcot-Marie-Tooth syndrome) neuromuscular junction (myasthenia gravis), muscle fiber (mitochondrial myopathy, muscular dystrophy, myotonic dystrophy)

**History and Physical Exam**
- proper assessment of tone requires accurate determination of GA
- differentiate between UMN and LMN lesion: spontaneous posture (spontaneous movement, movement against gravity, frog-leg position); muscle weakness; joint mobility (hyperextensibility); muscle bulk; presence of fasciculations
- postural maneuvers
  - traction response: pull to sit, look for flexion of arms to counteract traction and head lag
  - axillary suspension: suspend infant by holding at axilla and lifting; hypotonic babies will slip through grasp because of low shoulder girdle tone
  - ventral suspension: infant is prone and supported under the abdomen by one hand; infant should be able to hold up extremities; inverted “U” posturing demonstrates hypotonia
- dysmorphic features, cognitive ability, reflexes, strength

**Investigations**
- rule out systemic disorders (e.g. electrolytes, ABG, blood glucose, CK, and serum/urine investigations for multiple etiologies including mitochondrial causes)
- neuroimaging: MRI/MRA when indicated
- EMG, muscle biopsy/NCS
- chromosome analysis, genetic testing, metabolic testing, neuromuscular testing

**Treatment**
- depends on etiology: some treatments available for specific diagnosis
- counsel parents on prognosis and genetic implications
- refer patients for specialized care, refer for rehabilitation, OT, PT, assess feeding ability

### Cerebral Palsy

**Definition**
- a symptom complex, not a disease
- non-progressive central motor impairment syndrome due to insult to or anomaly of the immature CNS
- incidence: 1.5-2.5/1,000 live births (industrialized nations)
- life expectancy is dependent on the degree of mobility and intellectual impairment, not on severity of CNS lesion
Etiology
- Often obscure, no definite etiology identified in 1/3 of cases
- 10% related to intrapartum asphyxia; 10% due to postnatal insult (infections, asphyxia, prematurity with IVH and trauma)
- Association with LBW babies

Clinical Presentation
- General signs: delay in motor milestones, developmental delay, learning disabilities, visual/hearing impairment, seizures, microcephaly, uncoordinated swallow (aspiration)

Table 43. Types of Cerebral Palsy

Investigations
- May include metabolic screen, chromosome studies, serology, neuroimaging, EMG, EEG (if seizures), ophthalmology assessment, audiology assessment

Treatment
- Maximize potential through multidisciplinary services such as primary care physician, OT, PT, SLP, school supports, etc.
- Orthopedic management (e.g. dislocations, contractures, rhizotomy)
- Management of symptoms: spasticity (baclofen, Botox®), constipation (stool softeners)

Neurocutaneous Syndromes
- Characterized by tendency to form tumors of the CNS, PNS, viscera, and skin

NEUROFIBROMATOSIS TYPE I
- Autosomal dominant but 50% are the result of new mutations
- Also known as von Recklinghausen disease
- Incidence 1:3,000, mutation in NF1 gene on 17q11.2 (codes for neurofibromin protein)
- Learning disorders, abnormal speech development, and seizures are common
- Diagnosis of NF-1 requires 2 or more of:
  - ≥6 café-au-lait spots (>5 mm if prepubertal, >1.5 cm if postpubertal)
  - ≥2 neurofibromas of any type or one plexiform neurofibroma
  - ≥2 Lisch nodules (hamartomas of the iris)
  - Optic glioma
  - Freckling in the axillary or inguinal region
  - A distinctive bony lesion (e.g. sphenoid dysplasia, cortical thinning of long bones)
  - A first degree relative with confirmed NF-1

NEUROFIBROMATOSIS TYPE II
- Autosomal dominant
- Incidence 1:33,000
- Characterized by predisposition to form intracranial, spinal tumors
- Diagnosed when either bilateral vestibular schwannomas are found, or a first-degree relative with NF-2 and either a neurofibroma, meningioma, glioma, or schwannoma is found
- Also associated with posterior subcapsular cataracts
- Treatment consists of monitoring for tumor development and surgery
Respirology

Approach to Dyspnea

- determine if patient is sick or not sick; ABCs
- history: onset, previous episodes, precipitating events, associated symptoms, past medical/family history of respiratory disease
- physical exam: vitals, SpO₂, evidence of cyanosis, respiratory, cardiovascular
- investigations: CBC and differential, electrolytes, BUN, Cr, NP swab, ABG, CXR, ECG (based on clinical findings)

**Figure 16. Approach to dyspnea in childhood**

Upper Respiratory Tract Diseases

- see Otolaryngology, OT45
- diseases above the thoracic inlet characterized by inspiratory stridor, hoarseness, and suprasternal retractions
- differential diagnosis of stridor: croup, bacterial tracheitis, epiglottitis, foreign body aspiration, subglottic stenosis (congenital or iatrogenic), laryngomalacia/tracheomalacia (collapse of airway cartilage on inspiration)

**Table 44. Common Upper Respiratory Tract Infections in Children**

Lower Respiratory Tract Diseases

- obstruction of airways below thoracic inlet, produces more expiratory sounds
- classic symptom: wheezing

Differential Diagnosis of Wheezing

- common: asthma (recurrent wheezing episodes, identifiable triggers, typically over 6 yr), bronchiolitis (first episode of wheezing, usually under 1 yr), recurrent aspiration (often neurological impairment), pneumonia (fever, cough, malaise)
- uncommon: foreign body (acute unilateral wheezing and coughing), CF (prolonged wheezing, unresponsive to therapy), bronchopulmonary dysplasia (often develops after prolonged ventilation in the newborn)
- rare: CHF, mediastinal mass, bronchiolitis obliterans, tracheobronchial anomalies

Pneumonia

Etiology

- inflammation of pulmonary tissue, associated with consolidation of alveolar spaces

Clinical Presentation

- incidence is greatest in first year of life with viral causes being most common in children <5 yr
- cough, wheeze, stridor, fever, tachypnea
- CXR: diffuse, streaky infiltrates bilaterally
- bacterial causes may present with cough, fever, chills, dyspnea, more dramatic CXR changes (e.g. lobar consolidation, pleural effusion)

Management

- supportive therapy: hydration, antipyretics, humidified O₂

Bronchiolitis

Definition

- LRTI that has wheezing and signs of respiratory distress

Epidemiology

- the most common LRTI in infants, affects 50% of children in first 2 yr of life; peak incidence at 6 mo, winter or early spring
- increased incidence of asthma in later life

Etiology

- RSV (50%), parainfluenza, influenza, rhinovirus, adenovirus, M. pneumoniae (rare)

Clinical Presentation

- prodrome of URTI with cough and fever
- feeding difficulties, irritability
- wheezing, crackles, respiratory distress, tachypnea, tachycardia, retractions, poor air entry; symptoms often peak at 3-4 d
Investigations
- CXR (only in severe disease, poor response to therapy, chronic episode): air trapping, peribronchial thickening, atelectasis, increased linear markings
- NP swab: direct detection of viral antigen (immunofluorescence)
- WBC can be normal

Treatment
- self-limiting disease with peak symptoms usually lasting 2-3 wk
- mild to moderate distress
  - supportive: PO or IV hydration, antipyretics for fever, regular or humidified high flow O2
  - severe distress
    - as above + intubation and ventilation as needed
    - consider rebetol (Ribavirin®) in high risk groups: bronchopulmonary dysplasia, CHD, congenital lung disease, immunodeficient
- monthly RSV-Ig or palivizumab (monoclonal antibody against the F-glycoprotein of RSV) is protective against severe disease in high risk groups; case fatality rate <1%
- antibiotics have no therapeutic value unless there is secondary bacterial pneumonia
- indications for hospitalization
  - hypoxia: O2 saturation <92% on initial presentation
  - persistent resting tachypnea >60/min and retractions after several salbutamol masks
  - past history of chronic lung disease, hemodynamically significant cardiac disease, neuromuscular problem, immunocompromised
  - young infants <6 mo old (unless extremely mild)
  - significant feeding problems
  - social problem (e.g. inadequate care at home)

Asthma
Definition
- see Respirology. R7
- characterized by recurrent episodes of airway hyperreactivity, bronchospasm, and inflammation; reversible small airway obstruction
- very common, presents most often in early childhood
- associated with other atopic diseases such as allergic rhinitis or atopic dermatitis

Clinical Presentation
- episodic bouts of wheezing, dyspnea, tachypnea, cough (usually at night/early morning, with activity, or cold exposure)
- physical exam may reveal hyper-resonant chest, prolonged expiration, wheeze

Triggers
- URTI (viral or Mycoplasma), weather (cold exposure, humidity changes), allergens (pets), irritants (cigarette smoke), exercise, emotional stress, drugs (ASA, β-blockers)

Classification
- mild: occasional attacks of wheezing or coughing (<2/wk); symptoms respond quickly to inhaled bronchodilator; never needs systemic corticosteroids
- moderate: more frequent episodes with symptoms persisting and chronic cough; decreased exercise tolerance; sometimes needs systemic corticosteroids
- severe: daily and nocturnal symptoms; frequent ED visits and hospitalizations; usually needs systemic corticosteroids

Management
- acute
  - O2 (keep O2 saturation ≥90%) and fluids if dehydrated
  - β2-agonists: salbutamol (Ventolin®) MDI + spacer 4-8 puffs every 20 min for 3 doses, then every 1-4 h as needed; nebulized 0.15 mg/kg (minimum 2.5 mg) every 20 min for 3 doses then 0.15-0.3 mg/kg every 1-4 h as needed or 0.5 mg/kg continuous nebulization
  - ipratropium bromide (Atrovent®) if severe: MDI + spacer, 4-8 puffs every 20 min as needed up to 3 h; nebulized 0.25-0.5 mg every 20 min for 3 doses, then as needed
  - steroids: prednisone (1-2 mg/kg x 5 d) or dexamethasone (0.3 mg/kg/d x 5 d or 0.6 mg/kg/d x 2 d); in severe disease, use IV steroids
  - continue to observe; can discharge patient if asymptomatic for 2-4 h after last dose
- chronic
  - step-wise approach for management for ages 0-11: ≥12 yr follow adult guidelines
  - step 1 for intermittent asthma; steps 2-6 for persistent asthma requiring daily medication (step up or down based on patient's asthma control):
    - step 1: short acting β2-agonists (SABA) PRN

National Heart, Lung, and Blood Institute Guidelines for Well-Controlled Asthma
- Daytime symptoms ≤2 d/wk
- Night time symptoms < 1 night/mo
- Normal physical activity
- Mild and infrequent exacerbations
- No work/school absenteeism
- Need for β-agonist ≤2 doses/wk
- FEV1, or peak expiratory flow >80% of personal best
- FEV1/FVC > 80%
- Exacerbations requiring oral systemic corticosteroids 0-1/yr
• step 2: low-dose inhaled corticosteroids (ICS) preferred; alternative: cromolyn or montelukast (or LTRA, nedocromil, or theophylline for ages 5-11)
• step 3: medium-dose ICS (OR low-dose ICS + long acting β2-agonist (LABA) for ages 5-11)
• step 4: medium-dose ICS + LABA or monteleukast
• step 5: high-dose ICS + LABA or monteleukast
• step 6: high-dose ICS + LABA or monteleukast + oral systemic corticosteroids
• at all steps
  • patient education, environmental control, management of comorbidities
  • quick relief medication: SABA as needed
  • consider injection immunotherapy for steps 2-4

indications for hospitalization

• decision to hospitalize is based on duration of symptoms, severity of symptoms, severity of obstruction, response to ED treatment, course and severity of previous exacerbations, medication use at time of exacerbation, access to medical care/medications, adequacy of home support, and presence of psychiatric illness

• individualized decision to admit to ward: FEV1 or PEF <70%; ongoing mild-moderate symptoms despite ED treatment

• admit to ICU: FEV1 or PEF <40%, PCO₂ ≥ 42 mmHg, physical exam shows severe symptoms, drowsiness, confusion

### Cystic Fibrosis

- see Respirology, R12

**Etiology**

• 1 per 3,000 live births, mostly Caucasians
• autosomal recessive, CFTR gene found on chromosome 7 (ΔF508 mutation in 70%, but >1,600 different mutations identified) resulting in a dysfunctional chloride channel on the apical membrane of cells
• leads to relative dehydration of airway secretions, resulting in impaired mucociliary transport and airway obstruction

**Clinical Presentation**

• neonatal: meconium ileus, prolonged jaundice, antenatal bowel perforation
• infancy: pancreatic insufficiency with steatorrhea and FTT (despite voracious appetite), anemia, hypoproteinemia, hyponatremia
• childhood: heat intolerance, wheezing or chronic cough, recurrent chest infections (S. aureus, P. aeruginosa, H. influenzae), hemoptysis, nasal polyps, distal intestinal obstruction syndrome, rectal prolapse, clubbing of fingers
• older patients: COPD, infertility (males), decreased fertility (female)

**Investigations**

• sweat chloride test x 2 (>60 mEq/L)
  • false positive tests: malnutrition, atopic dermatitis, hypothyroidism, hypoparathyroidism, GSD, adrenal insufficiency, G6PD, Klinefelter syndrome, technical issues, autonomic dysfunction, familial cholestasis syndrome
  • false negative tests: technical problem with test, malnutrition, skin edema, mineralocorticoids

**Management**

• nutritional counseling: high calorie diet, pancreatic enzyme replacements, fat soluble vitamin supplements
• management of chest disease: physiotherapy, postural drainage, exercise, bronchodilators, aerosolized DNAase and inhaled hypertonic saline, antibiotics (e.g. cephalosporin, clavulanic acid, ciprofloxacin, inhaled tobramycin depending on sputum C&S), lung transplantation
• genetic counseling

**Complications**

• respiratory failure, pneumothorax (poor prognostic sign), cor pulmonale (late), pancreatic fibrosis with DM, gallstones, cirrhosis with portal HTN, infertility (male)
• early death (current median survival in the US is 37.4 yr)

</table>

- must rule out infection, malignancy, and acute orthopedic conditions

**History**
- demographics (age, gender)
- pattern of onset and progression of symptoms (including acuity and chronicity)
- morning stiffness, limp/weight-bearing status, night pain
- joint involvement (type, distribution) ± spine (axial) involvement
- extra-articular manifestations and systemic symptoms
- functional status – activities of daily living
- family history (arthritis, IBD, psoriasis, spondyloarthropathies, uveitis, bleeding disorders, sickle cell anemia)
- past medical illness, intercurrent infection, travel, sick contact history, joint injury

**Physical Exam**
- growth parameters
- screening examination (pediatric gait, arms, legs, spine exam)
- joint exam: inspection/palpation (swelling, erythema, warmth, tenderness, deformity), ROM
- adjacent structures (bone, tendon, muscle, skin)
- leg length
- neurologic exam

**Investigations**
- basic: CBC and differential, blood smear, ESR, CRP, x-ray
- as indicated: blood (ANA, RF, culture, viral/bacterial serology, CK, PTT, sickle cell screen, immunoglobulins, complement), urinalysis, synovial fluid (cell count, Gram stain, culture), TB skin test, imaging, bone marrow aspiration, slit lamp exam

Red Flags for Limb Pain
- Fever, pinpoint pain/tenderness, pain out of proportion to degree of inflammation, night pain, weight loss, erythema
**Growing Pains**

**Epidemiology**
- age 2-12 yr, M=F

**Clinical Presentation**
- diagnosis of exclusion
- intermittent, non-articular pain in childhood with *normal physical exam findings*
- pain at night, often limited to the calf, shin, or thigh; typically short-lived and bilateral
- relieved by heat, massage, mild analgesics
- child is well, asymptomatic during the day, no functional limitation
- possible family history of growing pains

**Management**
- lab investigations not necessary if typical presentation; reassurance and supportive management

**Transient Synovitis of the Hip**

- benign, self-limited disorder, usually occurs after URTI, pharyngitis, AOM

**Epidemiology**
- age 3-10 yr, M>F

**Clinical Presentation**
- afebrile or low-grade fever, pain typically occurs in hips, knees (referred from hip); painful limp but full ROM (pain not as pronounced as in joint or bone infections)
- symptoms resolve over 7-10 d

**Investigations**
- WBC within normal limits; ESR and CRP may be mildly elevated
- joint effusions may be seen on imaging
- diagnosis of exclusion (rule out septic arthritis and osteomyelitis)

**Treatment**
- symptomatic and anti-inflammatory medications

**Septic Arthritis and Osteomyelitis**

- MEDICAL EMERGENCY
- see Orthopedics, OR10

**Juvenile Idiopathic Arthritis**

- a heterogenous group of conditions characterized by persistent arthritis in children <16 yr
- diagnosis: arthritis in ≥1 joint(s); duration ≥6 wk; onset age <16 yr old; exclusion of other causes of arthritis; classification defined by features/number of joints affected in the first 6 mo of onset

**Systemic Arthritis (Still’s Disease)**
- onset at any age, M=F
- once or twice daily fever spikes (>101.3°F) ≥2 d/wk; children usually acutely unwell during fever episodes
- extra-articular features: erythematous “salmon-colored” maculopapular rash, lymphadenopathy, hepatosplenomegaly, leukocytosis, thrombocytosis, anemia, serositis
• arthritis may occur weeks to months later
• high ESR, CRP, WBC, platelet count

**Oligoarticular Arthritis (1-4 joints)**
• onset early childhood, F>M
• persistent: affects no more than 4 joints during the disease course
• extended: affects more than 4 joints after the first 6 mo
• typically affects large joints: knees > ankles, elbows, wrists; hip involvement unusual
• ANA positive ~60-80%, RF negative
• screening eye exams for asymptomatic anterior uveitis (occurs in ~30%)
• complications: knee flexion contracture, quadriceps atrophy, leg-length discrepancy, growth disturbances

**Polyarticular Arthritis (5 or more joints)**
• RF negative
  • onset: 2-4 yr and 6-12 yr, F>M
  • symmetrical involvement of large and small joints of hands and feet, TMJ, cervical spine
• RF positive
  • onset: late childhood/early adolescence, F>M
  • similar to the aggressive form of adult rheumatoid arthritis
  • severe, rapidly destructive, symmetrical arthritis of large and small joints
  • may have rheumatoid nodules at pressure points (elbows, knees)
  • unremitting disease, persists into adulthood

**Enthesitis-Related Arthritis**
• onset: late childhood/adolescence, M>F
• arthritis and/or enthesitis (inflammation at the site where tendons or ligaments attach to the bone)
• weight bearing joints, especially hip and intertarsal joints
• risk of developing ankylosing spondylitis in adulthood

**Psoriatic Arthritis**
• onset: 2-4 yr and 9-11 yr, F>M
• arthritis and psoriasis OR arthritis and at least two of
  • dactylitis, nail abnormalities, or family history of psoriasis in a 1st degree relative
  • asymmetric or symmetric small or large joint involvement

**Management**
• goals of therapy: eliminate inflammation, prevent joint damage, promote normal growth and development as well as normal function, minimize medication toxicity
• exercise to maintain ROM and muscle strength
• multidisciplinary approach: OT/PT, social work, orthopedics, ophthalmology, rheumatology
• 1st line drug therapy: NSAIDs, intra-articular corticosteroids
• 2nd line drug therapy: DMARDs (methotrexate, sulfasalazine, leflunamide), corticosteroids (acute management of severe arthritis, systemic symptoms of JIA, topical eye drops for uveitis), biologic agents

**Reactive Arthritis**
• see Rheumatology, RH24
• arthritis (typically the knee) follows bacterial infection, especially with *Salmonella, Shigella, Yersinia, Campylobacter, Chlamydia*, and most commonly *Streptococcus* (post-streptococcal reactive arthritis)
• typically resolves spontaneously
• may progress to chronic illness or Reiter’s syndrome (urethritis, conjunctivitis)

**Lyme Arthritis**
• see Infectious Diseases, ID23
• caused by spirochete *Borrelia burgdorferi*
• incidence highest among 5-10 yr olds
• do not treat children <8 yr old with doxycycline (may cause permanent tooth discoloration)
Systemic Lupus Erythematosus
- see Rheumatology, RH11
- autoimmune illness affecting multiple organ systems
- incidence 1/1,000, more commonly age >10, F:M = 10:1
- childhood-onset SLE vs. adult-onset SLE: children have more active disease, are more likely to have renal disease, and children receive more intensive drug therapy and have a poorer prognosis

Vasculitides

HENOC-H-SCHÖNLEIN PURPURA
- most common vasculitis of childhood, peak incidence 4-10 yr, M:F = 2:1
- vasculitis of small vessels
- often have history of URTI 1-3 wk before onset of symptoms

Clinical Presentation
- clinical triad: 1) palpable purpura, 2) abdominal pain, 3) arthritis
- skin: palpable, non-thrombocytopenic purpura in lower extremities and buttocks, edema, scrotal swelling
- joints: arthritis/arthritis involving large joints associated with painful edema
- GI: abdominal pain, GI bleeding, intussusception
- renal: microscopic hematuria, IgA nephropathy, proteinuria, HTN, renal failure in <5%

Management
- mainly supportive
- anti-inflammatory medications for joint pain, corticosteroids for select patients
- monitor for protein on urinalysis every month for 6 mo, checking for renal disease, which may develop late (immunosuppressive therapy if severe)

Prognosis
- self-limited, resolves within 4 wk
- recurrence in about one-third of patients
- long-term prognosis dependent on severity of nephritis

KAWASAKI DISEASE
- acute vasculitis of unknown etiology (likely triggered by infection)
- medium-sized vasculitis with predilection for coronary arteries
- most common cause of acquired heart disease in children in developed countries
- peak age: 3 mo-5 yr; Asians > Blacks > Caucasians

Diagnostic Criteria
- fever persisting ≥5 d AND ≥4 of the following features
  1. bilateral, non-exudative conjunctival injection
  2. oral mucous membrane changes (fissured lips, strawberry tongue, injected pharynx)
  3. changes of the peripheral extremities
     - acute phase: edema of hands, feet, palms, or soles
     - subacute phase: periungual desquamation
  4. polymorphous rash
  5. cervical lymphadenopathy >1.5 cm in diameter (usually unilateral)
- exclusion of other diseases (e.g. scarlet fever, measles)
- atypical Kawasaki disease: fever persisting ≥5 d and 2-3 of the above criteria
  - further evaluation dictated by CRP, ESR, and supplemental laboratory criteria

Management
- high (anti-inflammatory) dose of ASA while febrile
- low (anti-platelet) dose of ASA in subacute phase until platelets normalize, or longer if coronary artery involvement
- IVlg (2 g/kg) within 10 d of onset reduces risk of coronary aneurysm formation
- baseline 2D-Echo and follow up periodic 2D-Echo (usually at 6 wk)

Complications
- coronary artery vasculitis with aneurysm formation occurs in 20-25% of untreated children, <5% if receive IVlg within 10 d of fever
- 50% of aneurysms regress within 2 yr
- anticoagulation for multiple or large coronary aneurysms
- risk factors for coronary disease: male, age <1 or >9 yr, fever >10 d, Asian or Hispanic ethnicity, thrombocytopenia, hyponatremia

Basic Surgical Techniques

Sutures and Suturing

ANESTHESIA
- debride and irrigate before injecting anesthetic
- toxicity of mixtures (i.e., lidocaine + bupivicaine) is no greater than its individual components

Table 5. Toxic Limit and Duration of Action (1 cc of 1% solution contains 10 mg lidocaine)

<table>
<thead>
<tr>
<th></th>

</thead>
<tbody>
<tr>
<td>Lidocaine (Xylocaine&lt;sup&gt;®&lt;/sup&gt;)</td>
<td>5 mg/kg, lasts 45-60 min</td>
<td>7 mg/kg, lasts 2-6 h</td>
</tr>
<tr>
<td>Bupivicaine (Marcaine&lt;sup&gt;®&lt;/sup&gt;) for longer analgesic effect</td>
<td>2 mg/kg, lasts 2-4 h</td>
<td>3 mg/kg, lasts 3-7 h</td>
</tr>
</tbody>
</table>

IRRIGATION AND DEBRIDEMENT
- irrigate copiously with a physiologic solution such as Ringer’s lactate or normal saline to remove surface clots, foreign material, and bacteria
- debride all obviously devitalized tissue, irregular or ragged wounds must be excised to produce sharp wound edges that will assist healing when approximated

SUTURES
- use of a particular suture material is highly dependent on surgeon preference
- suture material divided into absorbable vs. non absorbable and monofilament vs. braided

Table 6. Suture Materials: Absorbable vs. Non-absorbable and Monofilament vs. Multifilament

<table>
<thead>
<tr>

</tr>
<tr>
<td>Multifilament</td>
<td>AVOID in contaminated wounds (increased likelihood of bacterial trapping)</td>
<td>Vicryl&lt;sup&gt;®&lt;/sup&gt; and Silk</td>
<td>Less memory/stiffness thus easier to work with</td>
</tr>
</tbody>
</table>

Basic Suturing Techniques

Basic Suture Methods
- simple interrupted: can be used in almost all situations
- sub-cuticular: good cosmetic result but weak, used in combination with deep sutures; not used in trauma
- vertical mattress: for areas difficult to evert (e.g., dorsum of the hand)
- horizontal mattress: everting, time saving
- continuous over and over (i.e., “running”, “baseball stitch”): time saving, good for hemostasis

Basic Principles
- minimize tissue trauma: follow curve of needle, insert and exit at 90 degrees to the wound edge, handle wound edges gently (use toothed forceps), use just enough tension to approximate edges (do not strangulate)
- use the finest needle and suture possible
- ensure good cosmesis

Other Skin Closure Materials
- tapes: may be indicated for superficial wounds and those with opposable edges. Tape cannot be used on actively bleeding wounds. When placed across the incision, will prevent surface marks and can be used primarily or after surface sutures have been removed. Tape burns may occur if there is excessive tension or swelling around the incision
- skin adhesives: e.g., 2-octylcyanoacrylate (e.g., Dermabond<sup>®</sup>) works well on small areas without much tension or shearing; may cause irreversible tattooing
- staples: steel-titanium alloys that incite minimal tissue reaction (healing is comparable to wounds closed by suture)
- traumatic tattoos are permanent discolorations resulting from new skin growth over foreign material or dirt left behind in the dermis. Copious irrigation and debridement should be done ASAP
Excision

- plan your incision along relaxed skin tension lines to minimize appearance of scar
- use elliptical incision to prevent "dog ears" (heaped up skin at end of incision) so the length of the ellipse should be 3x the width
- if needed, undermine skin edges to decrease wound tension
- use layered closure including dermal sutures when wound is deeper than superficial (decreases tension)

Skin Biopsy Types and Techniques

SHAVE BIOPSY
- used for superficial lesions where sampling of the full thickness of the dermis is not necessary
- most suitable lesions for shave biopsies are either elevated above the skin or have pathology confined to the epidermis (e.g. seborrheic or actinic keratoses, skin tags, warts, and superficial basal cell or squamous cell carcinomas)
- rapid, requires little training, and does not require sutures for closure
- will leave a circular scar
- can leave an indented scar
- heals by secondary intent
- should not be used for pigmented lesions – an unsuspected melanoma cannot be properly staged if partially removed

INCISIONAL BIOPSY
- can either be a punch biopsy
- or can be an ellipse including the lesion
- gives pathologists a portion of the lesion and the border with normal skin too

PUNCH BIOPSY
- involves the removal of a core-shaped piece of tissue, performed with round, disposable knives ranging in diameter from 2-10 mm
- allows sampling of the deep dermis
- can be used for the diagnosis and treatment of small pigmented lesions and atypical moles
- punch biopsy wounds can be closed with suture or left to heal by secondary intention. Punches greater than 3 mm may produce scarring and are best closed with one or two sutures
- has low incidence of infection, bleeding, nonhealing, significant scarring

EXCISIONAL BIOPSY
- performed for lesions that require complete removal for diagnostic or therapeutic purposes
- performed for lesions that cannot be adequately punch biopsied due to size, depth, or location
- requires the greatest amount of expertise and time
- always requires sutures for closure

TECHNIQUE

General
- all biopsies performed in clinic are done using aseptic technique, but are not sterile
- sterile gloves are indicated for biopsies and excisions in all patients

Preparing the Site
- common skin antiseptics (betadine, chlorhexidine) can be used to prepare the biopsy site
- chlorhexidine is used in concentrations ranging from 0.5-4%. This higher concentration cannot be used on the face as it could get into the eyes or ears and may burn or cause damage; most chlorhexidine preps also contain alcohol which can be flammable, so allow to dry before the biopsy and certainly before using any cautery
- mark the intended lesion and surgical margins with a surgical marker since they may be temporarily obliterated following injection of the anesthetic
- for all biopsies, a sterile drape technique is indicated. A fenestrated surgical drape is placed around the biopsy site after the area is cleansed and anesthetized

Anesthesia
- most commonly used local anesthetic is 1% or 2% lidocaine (with epinephrine)
- small amounts of epinephrine are added to constrict blood vessels, decrease bleeding, prolong anesthesia, and limit lidocaine toxicity. The local with epinephrine can be injected directly into the lesion
- local anesthetics with epinephrine may be used anywhere in the body (including the digits – except if the digits have been significantly injured and could have vascular compromise – e.g. saw injury)
- a field block should be performed for larger lesions by placing a ring of anesthetic around the surgical site, advancing and injecting through a site that has been previously anesthetized
Wounds

Causal Conditions

- laceration: cut or torn tissue
- abrasion: superficial skin layer is removed, variable depth
- contusion: injury caused by forceful blow to the skin and soft tissue; entire outer layer of skin intact yet injured
- avulsion: tissue/limb forcefully separated from surrounding tissue, either partially or fully; “de-gloving”
- puncture wounds: opening relatively small as compared with depth (e.g. needle)
  - includes bite wounds
- crush injuries: caused by compression
- thermal and chemical wounds

Principles of Wound Healing

- wound: disruption of the normal anatomical relationships of tissue as a result of injury

STAGES OF WOUND HEALING

- growth factors released by tissues play an important role
- scar is mature once it has completed the final stage, usually after 1 yr

FACTORS INFLUENCING WOUND HEALING

Local (reversible/controllable)
- mechanical (local trauma, tension)
- blood supply (ischemia/circulation)
- temperature
- technique and suture materials
- retained foreign body
- infection
- hematoma/seroma (↑ infection rate)
- venous HTN
- peripheral vascular disease

General (often irreversible)
- age
- nutrition (protein, vitamin C, O₂)
- smoking
- chronic illness (e.g. DM, cancer, CVD)
- immunosuppression (steroids, chemo, radiation)
- collagen vascular disease
- tissue irradiation

Myofibroblasts are the cells responsible for wound contraction; they do this at a rate of less than 0.75 mm/d

---

**Figure 14. Stages of wound healing**

**PHASE**

1. Inflammatory Phase (Reactive) (Days 1-6)
   - Limits damage, prevents further injury
   - Debris and organisms cleared via inflammatory response:
     - Neutrophils (24-48 h)
     - Macrophages: critical to wound healing by orchestrating growth factors for collagen production (48-96 h)
     - Lymphocytes: role poorly defined (5-7 d)

2. Proliferative Phase (Regenerative) (Day 4 – Week 3)
   - Fibroblasts attracted and activated by macrophage growth factors
   - Reparative process: re-epithelialization, matrix synthesis, angiogenesis (relieves ischemia)
   - Tensile strength begins to increase at 4-5 d

3. Remodeling Phase (Maturation) (Week 3 – 1 year)
   - Increasing collagen organization and stronger crosslinks
   - Type I collagen replaces Type III until normal 4:1 ratio achieved
   - Peak tensile strength at 60 d – 80% of preinjury strength

**PROCESS**

1. Hemostasis – vasoconstriction + platelet plug
2. Chemotaxis – migration of macrophages and PMN

1. Collagen synthesis (mainly type III)
2. Angiogenesis
3. Epithelialization

1. Contraction
2. Scarring
3. Remodeling of scar
**ABNORMAL HEALING**

**Hypertrophic Scar**
- scar remains roughly within boundaries of original injury
- red, raised, widened, frequently pruritic
- usually caused by excess tension on a wound or delayed closure (as in burn wounds)
- common sites: back, shoulder, sternum, angle of mandible
- treatment: pressure garments, silicone gel sheeting, corticosteroid injection, surgical excision if other options fail (however, may still recur), fractional carbon dioxide ablative laser
- typically improves with time

**Keloid Scar**
- scar extends beyond boundaries of original injury
- frequently pruritic, often painful; collagen in whorls rather than bundles
- common sites: sternum, deltoid, earlobe; more common in darker skinned people
- treatment: pressure garments, silicone gel sheeting, corticosteroid injection, radiation therapy ± surgical excision as a last resort
- unlike hypertrophic scar, this is due to a derrangement in normal wound healing caused by over-active fibroblasts due to excessive transforming growth factor-beta expression

**Chronic Wound**
- fails to heal primarily within 4-6 wk
- common chronic wounds include diabetic, pressure and venous stasis ulcers
- treatment: may heal with meticulous wound care; may also require surgical intervention
- Marjolin’s ulcer: squamous cell carcinoma arising in a chronic wound secondary to genetic changes caused by chronic inflammation → consider biopsy of chronic wound

**WOUND CLOSURE**

**Primary (1°) Closure (First Intention)**
- definition: wound closure by direct approximation of edges within hours of wound creation (i.e. with sutures, staples, skin graft, etc.)
- indication: recent (<6 h, longer with facial wounds), clean wounds
- contraindications: animal/human bites (except on face), crush injuries, infection, long time lapse since injury (>6-8 h), retained foreign body

**Secondary (2°) Closure/Spontaneous Healing (Second Intention)**
- definition: wound left open to heal spontaneously (epithelialization 1 mm/d from wound margins in concentric pattern), contraction (myofibroblasts) and granulation – maintained in inflammatory phase until wound closed; requires dressing changes; inferior cosmetic result
- indication: when 1° closure not possible or indicated (see Primary Closure)

**Tertiary (3°) Closure/Delayed Primary Closure (Third Intention)**
- definition: intentionally interrupt healing process (e.g. with packing), then wound can be closed at 4-10 d post-injury after granulation tissue has formed and there is <10^5 bacteria/gram of tissue
- indication: contaminated (high bacterial count), long time lapse since initial injury, severe crush component with significant tissue devitalization, closure of fasciotomy wounds
- prolongation of inflammatory phase decreases bacterial count and lessens chance of infection after closure

**Contaminated and Infected Wounds**

**Definitions**
- contamination: the presence of non-replicating microorganisms within a wound
- colonization: the presence of replicating microorganisms within a wound
- infection: greater than 10^5 microorganisms in a wound without intact epithelium, a wound may also be infected with small amounts of a very virulent organism (e.g. GBS)

**Management of Acute Contaminated Wound (<24 h)**
- cleanse and irrigate open wound with physiologic solution (NS or RL)
- evaluate for injury to underlying structures (vessels, nerve, tendon and bone)
- control active bleeding
- debridement: removal of foreign material, devitalized tissue, old blood
  - surgical debridement: blade and irrigation if indicated
- systemic antibiotics are commonly indicated for obvious infection, wound older than 8 h, severely contaminated, human/animal bites, immunocompromised, involvement of deeper structures (e.g. joints, fractures)
- ± tetanus toxoid 0.5 mL IM ± tetanus immunoglobulin 250 U deep IM (see Table 7 and Table 8)
• ± post-exposure treatment of
  - hepatitis B, HIV, hepatitis C (if titres confirmed at 6 mo)
• re-evaluate in 24-48 h for signs of deep infection
  - open infected portion of wound by removing sutures if evidence of infection (i.e. erythema, warmth, pain, discharge)

</table>

- 0.5 mL of combined tetanus and diphtheria toxoids = acellular pertussis
- ^Tetanus immune globulin, 250 U given at a separate site from Td/Tdap
- ~Yes, if > 10 yr since last booster
- ¶Yes, if immunocompromised
- §Yes, if > 5 yr since last booster

Management of Contaminated Wounds (>24 h, including Ulcers)
• irrigation and debridement
  - traumatic tattooing can occur if foreign materials left in wound
• systemic antibiotics indicated if there is concern of infection (e.g. redness, swelling, pain, clinically unwell)
• topical antimicrobials: beneficial for minor wounds, but no additional benefit for wounds requiring systemic antibiotics. May aid in healing of chronic wounds
• closure: final closure via secondary intention (most common), delayed wound closure (3º closure), skin graft or flap; successful closure depends on bacterial count of ≤10³/cm³ prior to closure and frequent dressing changes

BITES
• see Emergency Medicine, ER46

Dog and Cat Bites
• pathogens: Pasteurella multocida, S. aureus, S. viridans
• investigations: same as for human bites
• treatment: Clavulin® (500 mg PO q8h started immediately – amoxicillin + clavulanic acid)
  - consider rabies prophylaxis if animal has symptoms of rabies or unknown animal
  - ± rabies lq (20 IU/kg around wound, or 1M) and 1 of the 3 types of rabies vaccines (1.0 mL 1M in deltoid, repeat on days 3, 7, 14, 28)
  - aggressive irrigation with debridement
  - healing by secondary intention is mainstay of treatment
  - only consider primary closure for bite wounds on the face; otherwise primary closure is contraindicated
  - contact Public Health if animal status unknown

Human Bites
• pathogens: Staphylococcus > α-hemolytic Streptococcus > Eikenella corrodens > Bacteroides
• mechanism: most commonly over dorsum of MCP from a punch in mouth; “fight-bite”
• serious, as mouth has 10⁹ microorganisms/mL, which get trapped in joint space when fist unclenches and overlying skin forms an air-tight covering ideal for anaerobic growth – can lead to septic arthritis
• investigations
  - radiographs prior to therapy to rule out foreign body (e.g. tooth) or fracture
  - culture for aerobic and anaerobic organisms, Gram stain
• treatment
  ▪ urgent surgical exploration of joint, drainage and debridement of infected tissue
  ▪ wound must be copiously irrigated
  ▪ Clavulin® 500 mg PO q8h, clindamycin 300 mg PO q6h + ciprofloxacin 500 mg PO q12h
    (if allergic to penicillin) + secondary closure
  ▪ splint

Dressings

• dressing selection depends on the wound characteristics
  ▪ as the wound progresses through healing it will require different types of dressings, therefore, routine inspection is recommended
  ▪ principles of dressings
    • moist vs. dry wounds
      – purpose of dressings should be to keep wound appropriately moist (i.e. moistening dry wounds or removing excess exudate/blood from wet wounds)
    • clean vs. infected wounds
      – clean wounds can be dressed with petroleum based gauze, which is non-adhering to epithelializing tissue; requires secondary dressing
      – infected wounds can be dressed with iodine gauze, silver-containing, or antimicrobial dressings
    • wide-based vs. cavitary/tunneling wounds
      – cavitary or tunnelling wounds (i.e. through a fascial layer) can be packed with saline-soaked (non-infected), betadine or chlorpactin-soaked (infected) ribbon gauze, or other easily retrievable one-piece moisture providing dressing

Table adapted from Grabb & Smith’s Plastic Surgery, 6th ed. Chapter 3, Table 3.3

Reconstruction

SKIN GRAFTS

Definition
• skin that is harvested from a donor site and transferred to the recipient site and that does not carry its own blood supply. Survival requires diffusion of nutrients during the first 24-48 h (imbibition) followed by blood vessel connection between the donor site and graft (inosculation). They are classified according to the depth of dermis they contain: full thickness (entire epidermis + dermis) vs. split-thickness (epidermis + partial dermis)

Donor Site Selection
• must consider size, hair pattern, texture, thickness of skin, and color (facial grafts best if taken from "blush zones" above clavicle e.g. pre/post auricular or neck)
• partial thickness grafts usually taken from inconspicuous areas (e.g. buttocks, lateral thighs, etc.)

Partial Thickness Skin Graft Survival
• 3 phases of skin graft “take”
  1. plasmatic imbibition: diffusion of nutrition from recipient site (first 48 h)
  2. inosculation: vessels in graft connect with those in recipient bed (day 2-3)
  3. neovascular ingrowth: graft revascularized (day 3-5)
• requirements for survival
  ▪ bed: well-vascularized (unsuitable: bone, tendon, heavily irradiated, infected wounds, etc.)
  ▪ contact between graft and recipient bed: fully immobile (decreased shearing and hematoma formation)
  ▪ staples, sutures, splinting, and appropriate dressings (pressure) are used to prevent movement of graft and hematoma or seroma formation
  ▪ site: low bacterial count (<10⁷/cm³, to prevent infection
Classification of Skin Grafts

1. by species
   - autograft: from same individual
   - allograft (homograft): from same species, different individual
   - xenograft (heterograft): from different species (e.g. porcine)

2. by thickness

   Table 10. Skin Grafts

<table>
<thead>
<tr>

<td>Primary closure</td>
</tr>
<tr>
<td>Re-harvesting</td>
<td>~10 d (faster on scalp)</td>
<td>N/A</td>
</tr>
<tr>
<td>Graft Take</td>
<td>Easier; shorter nutrient diffusion distance</td>
<td>Lower rate of survival (thicker, slower vascularization)</td>
</tr>
<tr>
<td>Contraction</td>
<td>Less 1st contraction, greater 2nd contraction (less with thicker graft)</td>
<td>Greater 1st contraction, less 2nd contraction</td>
</tr>
<tr>
<td>Aesthetic</td>
<td>Poor</td>
<td>Good</td>
</tr>
<tr>
<td>Comments</td>
<td>Can be meshed for greater area</td>
<td>May use on face and fingers</td>
</tr>
<tr>
<td>Advantages</td>
<td>Takes well in less favorable conditions, can cover a larger area</td>
<td>Resists contraction, texture/pigment more normal</td>
</tr>
<tr>
<td>Disadvantages</td>
<td>Contracts significantly, abnormal pigmentation, high susceptibility to trauma</td>
<td>Requires well vascularized bed</td>
</tr>
<tr>
<td></td>
<td>Requires well vascularized bed</td>
<td>Must remove fat from graft before application</td>
</tr>
<tr>
<td>Uses</td>
<td>Large areas of skin, granulating tissue beds, burns</td>
<td>Face (color match), site where thick skin or decreased contracture is desired (e.g. finger)</td>
</tr>
</tbody>
</table>

- mesh graft
  - advantages
    - prevents accumulation of fluids (e.g. hematoma, seroma)
    - covers a larger area
  - disadvantages
    - poor cosmesis ("reptilian" appearance)
    - has significant contractures
- common reasons for graft loss: hematoma/seroma, infection, mechanical force (e.g. shearing, pressure)

OTHER GRAFTS

FLAPS

- definition: tissue transferred from one site to another with a known blood supply (random, pediced or named); not dependent on neovascularization, unlike a graft
- may consist of: skin, subcutaneous tissue, fascia, muscle, bone, other tissue (e.g. omentum)
- classification: based on blood supply to skin (random, axial) and anatomic location (local, regional, distant)
- indications for flaps
  - reconstruction: replaces tissue loss due to trauma or surgery
  - provides skin and temporary soft tissue coverage through which surgery can be carried out later
  - improves blood supply to poorly vascularized bed (e.g. bone)
- complications: flap loss due to hematoma, seroma, infection, poor flap design, extrinsic compression (dressing too tight) or vascular failure/thrombosis, fat necrosis (in free flaps)
Random Pattern Flaps
- blood supply by dermal and subdermal plexus to skin and subdermal tissue with random vascular supply
- limited length:width ratio to ensure adequate blood supply (typically 2:1)
- flap choice is often a combination of available tissue, location of reconstruction site with respect to donor site, and surgeon preference
- types
  - rotation: cover wounds of various sizes; common use: sacral pressure sores
  - transposition: smaller in size compared to rotation flaps and advancement flaps; commonly used on certain areas of the face using adjacent areas of excess skin laxity
  - Z-plasty: used to reorient a scar, lengthen the line of a scar or to break up a scar
  - advancement flaps (V-Y, Y-V)
    - single/bipedicle V-Y flaps: wounds with lax surrounding tissue; the pedicle is the deep tissue underlying the flap

Axial Pattern Flaps (Arterialized)
- flap contains a well defined artery and vein
- allows greater length:width ratio (5-6:1)
- types
  - peninsular flap: skin and vessel intact in pedicle
  - island flap: vessel intact, pedicle is better defined
  - free flap: vascular supply anastomosed at recipient site by microsurgical techniques
- can be sub-classified according to tissue content of flap:
  - e.g. musculocutaneous/myocutaneous (e.g. transverse rectus abdominal myocutaneous) vs. fasciocutaneous

Free Flaps
- transplanting expendable donor tissue from one part of the body to another by isolating and dividing a dominant artery and veins to a flap and performing a microscopic anastomosis between these and the vessels in the recipient wound
- survival rates >95%
- types: muscle and skin (common), bone, jejunum, omentum
  - e.g. radial forearm, scapular, latissimus dorsi

# Soft Tissue Infections

## Table 13. Classification of Soft Tissue Infections by Depth

<table>
<thead>
<tr>
<th>Soft Tissue Infection</th>
<th>Depth</th>
</tr>
</thead>
<tbody>
<tr>
<td>Erysipelas</td>
<td>Superficial with subcutaneous tissue involvement</td>
</tr>
<tr>
<td>Cellulitis</td>
<td>Full thickness with subcutaneous tissue involvement</td>
</tr>
<tr>
<td>Fasciitis</td>
<td>Fascia</td>
</tr>
<tr>
<td>Myositis</td>
<td>Muscle</td>
</tr>
</tbody>
</table>

## Erysipelas

**Definition**
- acute skin infection that is more superficial than cellulitis

**Etiology**
- typically caused by Group A β-hemolytic *Streptococcus*

**Clinical Features**
- intense erythema, induration, and **sharply demarcated borders** (differentiates it from other skin infections)

**Treatment**
- penicillin or first generation cephalosporin (e.g. cefazolin or cephalexin)

## Cellulitis

**Definition**
- non-suppurative infection of skin and subcutaneous tissues

**Etiology**
- skin flora most common organisms: *S. aureus*, β-hemolytic *Streptococcus*
- immunocompromised: Gram-negative rods and fungi

**Clinical Features**
- source of infection
  - trauma, recent surgery
  - foreign bodies (IV, orthopaedic pins)
  - systemic symptoms (fever, chills, malaise)
- pain, tenderness, edema, erythema with poorly defined margins, regional lymphadenopathy
- can lead to ascending lymphangitis (visible red streaking in skin proximal to area of cellulitis)

**Investigations**
- CBC, blood cultures
- culture and Gram stain wound/aspirate from wound if open wound
- plain radiographs if suspect foreign body or abscess or to rule out gas (if worried about a deeper infection, e.g. fasciitis) or rule out bone invasion (osteomyelitis)

**Treatment**
- antibiotics: first line – cephalaxin 500 mg PO q6h or cloxacillin 500 mg PO q6h x 7 d; if complicated (e.g. lymphangitis, DM) consider IV cefazolin 1-2 g q8h penicillin
- outline area of erythema to monitor success of treatment
- immobilize and splint (hands)

## Necrotizing Fasciitis

**Definition**
- rapidly spreading, very painful infection of the deep fascia with necrosis of tissues
- some bacteria create gas that can be felt as crepitus and be seen on x-rays
- infection spreads rapidly along deep fascial plane and is **limb and life threatening**

**Etiology**
- Type I: polymicrobial (less aggressive)
- Type II: monomicrobial, usually β-hemolytic *Streptococcus*
Clinical Features

- pain out of proportion to clinical findings and beyond border of erythema, edema, tenderness, ± crepitus (subcutaneous gas from anaerobes) ± fever
- infection spreads very rapidly
- hypotension and hyperglycemia are common findings
- patients may look deceptively well at first, but may rapidly become very sick/toxic
- late findings
  - skin turns dusky blue and black (secondary to thrombosis and necrosis)
  - induration, formation of bullae
  - cutaneous gangrene, subcutaneous emphysema

Investigations

- a clinical diagnosis
- CT scan only if suspect it is not necrotizing fasciitis (looking for abscess, gas collection, myonecrosis and possible source of infection)
- severely elevated CK: usually means myonecrosis (late sign)
- hemostat easily passed along fascial plane; fascial biopsy to rule out in equivocal situations

Treatment

- vigorous resuscitation (ABCs)
- urgent surgical debridement: remove all necrotic tissue, copious irrigation
- IV antibiotics: as appropriate for clinical scenario; consider penicillin 4 million IU IV q4h and clindamycin 900 mg IV q6h until final cultures available; clindamycin targets the toxin produced
- possible role for IVIg (especially in Group A strep, adjuvant treatment on a case by case basis)
- urgent consultation with infectious disease specialist is recommended

Ulcers

Lower Limb Ulcers

Traumatic Ulcers (Acute)

- failure of lesions to heal, usually due to compromised blood supply and unstable scar
- usually over bony prominence ± edema ± pigmentation changes ± pain
- treatment: debridement of ulcer and compromised tissue, left to heal via secondary intention with dressings, may need reconstruction with local or distant flap in select cases, vascular status of limb must be assessed clinically and via vascular studies (i.e. sonographically)

Non-Traumatic Ulcers (Chronic)

Table 14. Venous vs. Arterial vs. Diabetic Ulcers

</tbody>
</table>

**Pressure Ulcers**

**Common Sites**
- over bony prominences; 95% on lower body

**Stages of Development**
1. hyperemia: disappears 1 h after pressure removed
2. ischemia: follows 2-6 h of pressure
3. necrosis: follows >6 h of pressure
4. ulcer: necrotic area breaks down – N.B. skin is like tip of an iceberg

**Classification (National Pressure Ulcer Advisory Panel 2007)**
- Stage I: nonblanchable erythema present >1 h after pressure relief, skin intact
- Stage II: partial-thickness skin loss
- Stage III: full-thickness skin loss into subcutaneous tissue, but not through fascia
- Stage IV: through fascia into muscle, bone, tendon, or joint
  - if an eschar is present, must fully debride before staging possible

**Prevention**
- good nursing care (clean dry skin, frequent repositioning), special beds or mattress (Kin Air®), proper nutrition, activity, early identification of individuals at risk (e.g. immobility, incontinence, paraplegia, etc.)

**Treatment**
- depends on individual patient and condition
- treat underlying medical issues including nutrition
- continue with preventative measures (pressure relief)
- wound debridement, moisture retentive or antimicrobial dressing, regular reassessment
- topical antimicrobials at treating physician's discretion, systemic antibiotics for infections
- resect osteomyelitis and treat with 6 wk of antibiotics before final flap coverage
- assess for possible reconstruction after infection eradicated and clean wound bed (<10^5 colony-forming unit)

**Complications**
- cellulitis, osteomyelitis, sepsis, gangrene

**Burns**

**Burn Injuries**

**Causal Conditions**
- thermal (flame contact, scald)
- chemical
- radiation (UV, medical/therapeutic)
- electrical

**Most Common Etiology**
- children: scald burns
- adults: flame burns
Pathophysiology of Burn Wounds

- amount of tissue destruction is based on temperature, time of exposure, and specific heat of the causative agent
- zone of hyperemia: vasodilation from inflammation; entirely viable, cells recover within 7 d; contributes to systemic consequences seen with major burns
- zone of stasis (edema): decreased perfusion; microvascular sludging and thrombosis of vessels results in progressive tissue necrosis → cellular death in 24-48 h without proper treatment
  - factors favoring cell survival: moist, aseptic environment, rich blood supply
  - zone where appropriate early intervention has most profound effect in minimizing injury
- zone of coagulation (ischemia): no blood flow to tissue → irreversible cell damage → cellular death/necrosis

Diagnosis and Prognosis

- burn size
  - % of TBSA burned: rule of 9s for 2° and 3° burns only (children <10 yr old use Lund-Browder chart)
  - for patchy burns, surface area covered by patient’s palm (fingers closed) represents approximately 1% of TBSA
- age: more complications if <3 or >60 yr old
- depth: difficult to assess initially – history of etiologic agent and time of exposure helpful (see Table 16)
- location: face and neck, hands, feet, perineum are critical areas requiring special care of a burn unit (see Indications for Transfer to Burn Center, PL18)
- inhalation injury: can severely compromise respiratory system due to sloughing of the epithelium that blocks gas exchange at the alveolus; also significant swelling of the intraoral and laryngeal mucosa from the thermal injury as well as during massive resuscitation.
- associated injuries (e.g. fractures)
- comorbid factors (e.g. concurrent disability, alcoholism, seizure disorders, chronic renal failure) can exacerbate extent of injury

Prognosis best determined by:
- burn size (TBSA)
- age of patient
- presence/absence of inhalational injury

Indications for Transfer to Burn Center

**American Burn Association Criteria**

- patients with partial or full-thickness burns that involve the hands, feet, genitalia, face, eyes, ears and/or major joints or perineum
- partial thickness burns ≥20% TBSA in patients aged 10-50 yr old
- partial thickness burns ≥10% TBSA in children aged ≤10 or adults aged ≥50 yr old
- full thickness burns ≥5% TBSA in patients of all ages
- electrical burns, including lightening (internal injury underestimated by TBSA)
- chemical burns
- inhalation injury (high risk of mortality and may lead to respiratory distress)
- burn injuries in patients with medical comorbidities, could complicate management and recovery
- any patient with simultaneous trauma plus burns should be stabilized for trauma first, then triaged appropriately to burn center
- any patients with burn injury and who will require special emotional, social, and rehabilitation intervention
- children with burns in a hospital not equipped with pediatric care specialists
Acute Care of Burn Patients

- adhere to ATLS protocol
- resuscitation using Parkland formula to restore plasma volume and cardiac output and should only be used in burns 30% or greater TBSA
  - 4 cc RL/kg/% TBSA over first 24 h (1/2 within first 8 h of sustaining burn, 1/2 in next 16 h); if resuscitation is greater than 6cc/kg/%TBSA, reevaluate as this can create significant complications (compartment syndrome of extremities as well as abdomen which can impair ventilation); reasonable to supplement colloid in setting of excessive resuscitation
- extra fluid administration required if
  - burn >80% TBSA
  - 4° burns
  - associated traumatic injury
  - electrical burn
  - inhalation injury
  - delayed start of resuscitation
  - pediatric burns
- monitor resuscitation
  - urine output is best measure: maintain at >0.5 cc/kg/h (adults) and 1.0 cc/kg/h (children <12 yr)
  - maintain a clear sensorium, HR <120/min, MAP >70 mmHg
  - urine output will often lag early in the resuscitation
  - trend other signs of resuscitation, such as lactate, base deficit, CVP, mixed or central venous O₂
- burn specific care
  - relieve respiratory distress: intubation and/or escharotomy (see sidebar)
  - prevent and/or treat burn shock: at least 2 large bore IVs in non-burned area; place early central line and a-line if large burn identify and treat immediate life-threatening conditions (e.g. inhalation injury, CO poisoning)
  - determine TBSA affected first, since depth is difficult to determine initially (easier to determine after 24 h)
- tetanus prophylaxis if needed
  - all patients with burns >10% TBSA, or deeper than superficial partial thickness, need 0.5 cc tetanus toxoid
  - also give 250 U of tetanus Ig if prior immunization is absent/unclear, or the last booster >10 yr ago
- baseline laboratory studies (Hb, U/A, BUN, CXR, electrolytes, ECG, cross-match, ABG, carboxyhemoglobin)
- cleanse, debride, and treat the burn injury (antimicrobial dressings)
- early excision and grafting important for outcome

Respiratory Problems

- 3 major causes
  - burn eschar encircling chest
  - distress may be apparent immediately
  - perform escharotomy to relieve constriction
- CO poisoning
  - may present immediately or later
  - treat with 100% O₂ (decreases half-life of carboxyhemoglobin from 210 to 59 min) until carboxyHb <10%; can use hyperbaric chamber for very high levels if patient is otherwise stable
  - smoke inhalation leading to pulmonary injury
  - chemical injury to alveolar basement membrane and pulmonary edema (insidious onset)
  - risk of pulmonary insufficiency (up to 48 h) and pulmonary edema (48-72 h)
  - watch for secondary bronchopneumonia (3-25 d) leading to progressive pulmonary insufficiency
  - intubate patient with any signs of inhalation injuries

Burn Wound Healing

### Table 17. Burn Shock Resuscitation (Parkland Formula)

| Hour 0-24 | 4 cc RL/kg/% TBSA with 1/2 of total in first 8 h from time of injury and 1/2 of total in next 16 h from time of injury |
| Hour 24-30 | 0.35-0.5 cc plasma/kg/%TBSA, or decrease fluids by 1/3 from first 24 h assuming urine output remains stable |
| > Hour 30 | D5W at rate to maintain normal serum sodium |

*Do not forget to add maintenance fluid to resuscitation*
Table 18. Burn Wound Healing

<td>(do not re-epithelialize – cannot graft)</td>
</tr>
</tbody>
</table>

Treatment

- 3 stages
  1. assessment: depth determined
  2. management: specific to depth of burn and associated injuries
  3. rehabilitation
- first degree
  - treatment aimed at comfort
    - topical creams (pain control, keep skin moist) ± aloe
    - oral NSAIDs (pain control)
- superficial second degree
  - daily dressing changes with topical antibiotics, polysporin, may use a temporary biological or synthetic covering to close the wound
- deep second degree and third degree
  - prevent infection and sepsis (significant cause of death in burn patients)
    - most common organisms: *S. aureus*, *P. aeruginosa* and *C. albicans*
      - day 1-3 (rare): Gram-positive
      - day 3-5: Gram-negative (*Proteus, Klebsiella*)
    - topical antimicrobials: prevent bacterial infection (from skin flora, gut flora or caregiver) and secondary sepsis
    - remove dead tissue
    - surgically debride necrotic tissue, excise to viable (bleeding) tissue

Table 19. Topical Antibiotic Therapy for Burns

<table>
<thead>
<tr>
<th>Antibiotic</th>
<th>Pain with Application</th>
<th>Penetration</th>
<th>Adverse Effects</th>
</tr>
</thead>
<tbody>
<tr>
<td>Silver nitrate (0.5% solution)</td>
<td>None</td>
<td>Minimal</td>
<td>Stains (black), leaches sodium and magnesium from wounds</td>
</tr>
<tr>
<td>Nanocrystalline silver-coated dressing (Acticoat®)</td>
<td>None or transient</td>
<td>Medium, does not penetrate eschar; preferred over silver sulfadiazine and silver nitrate</td>
<td>May stain, producing a pseudoeschar or facial discoloration (argyria-like symptoms); raised liver enzymes</td>
</tr>
<tr>

</tbody>
</table>

- early excision and grafting is the mainstay of treatment
- initial dressing should decrease bacterial proliferation
- indication for skin graft: deep 2° or 3° burn that is > size of a quarter
- prevention of wound contractures: pressure dressings, joint splints, early physiotherapy

Other Considerations in Burn Management

Figure 21. Systemic effects of severe burns
- nutrition
  - hypermetabolism: TBSA >40% have BMR 2-2.5x predicted
  - calories, vitamin C, vitamin A, Ca²⁺, Zn²⁺, Fe²⁺
- immunosuppression and sepsis
  - must keep bacterial count <10⁵ bacteria/g of tissue (blood culture may not be positive)
  - signs of sepsis: sudden onset of hyper/hypothermia, unexpected CHF or pulmonary edema, development of ARDS, ileus >48h post-burn, mental status changes, azotemia, thrombocytopenia, hypofibrinogenemia, hyper/hypoglycemia (especially if burn >40% TBSA)
  - oxandrolone has been shown to help with burn induced hypermetabolism in burns over 30% TBSA; continue for up to 6 mo
- GI bleed may occur with burns >40% TBSA (usually subclinical)
  - treatment: tube feeding or NPO, antacids, H₂ blockers (preventative)
- renal failure secondary to under resuscitation, drugs, myoglobin, etc.
- progressive pulmonary insufficiency
  - can occur after: smoke inhalation, pneumonia, cardiac decompensation, sepsis
- wound contracture and hypertrophic scarring
  - largely preventable with timely wound closure, splinting, pressure garments and physiotherapy; can be treated with fractional ablative CO₂ laser

Special Considerations

CHEMICAL BURNS
- major categories: acid burns, alkaline burns, phosphorous burns, chemical injection injuries
- common agents: cement, hydrofluoric acid, phenol, tar
- mechanism of injury: chemical solutions coagulate tissue protein leading to necrosis
  - acids → coagulation necrosis
  - alkalines → saponification followed by liquefactive necrosis
- severity related to: type of chemical (alkali worse than acid), temperature, volume, concentration, contact time, site affected, mechanism of chemical action, degree of tissue penetration
- burns are deeper than they initially appear and may progress with time

Treatment (General)
- ABCs, monitoring
- remove contaminated clothing and brush off any dry powders before irrigation
- irrigation with water for 1-2 h under low pressure (contraindicated in heavy metal burns, such as sodium, potassium, magnesium, and lithium; in these cases soak in mineral oil instead)
- inspect eyes, if affected: wash with saline and refer to ophthalmology
- inspect nails, hair and webspaces
- correct metabolic abnormalities and tetanus prophylaxis if necessary
- local wound care 12 h after initial dilution (debridement)
- wound closure same as for thermal burn
- beware of underestimated fluid resuscitation, renal, liver, and pulmonary damage

Special Burns and Treatments

<table>
<thead>
<tr>
<th>Acid Burn</th>
<th>Water irrigation, followed by dilute solution of sodium bicarbonate</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hydrofluoric Acid</td>
<td>Water irrigation; clip fingernails to avoid acid trapping; topical calcium gel ± subcutaneous injection of calcium gluconate 10% calcium gluconate IV depending on amount of exposure and pain</td>
</tr>
<tr>
<td>Sulfuric Acid</td>
<td>Treat with soap/lime prior to irrigation, as direct water exposure produces extreme heat</td>
</tr>
<tr>
<td>Tar</td>
<td>Remove with repeated application of petroleum-based antibiotic ointments (e.g. Polysporin®)</td>
</tr>
</tbody>
</table>

ELECTRICAL BURNS
- depth of burn depends on voltage and resistance of the tissue (injury more severe in tissues with high resistance)
- often presents as small punctate burns on skin with extensive deep tissue damage which requires debridement
- electrical burns require ongoing monitoring as latent injuries can occur
- watch for system specific damages and abnormalities
  - abdominal: intraperitoneal damage
  - bone: fractures and dislocations especially of the spine and shoulder
  - cardiopulmonary: anoxia, ventricular fibrillation, arrhythmias
  - muscle: myoglobinuria indicates significant muscle damage → compartment syndrome
  - neurological: seizures and spinal cord damage
  - ophthalmology: ocular compartment syndrome and cataract formation (late complication)
  - renal: ATN resulting from toxic levels of myoglobin and hemoglobin
  - vascular: vessel thrombosis → tissue necrosis (increased Cr, K⁺ and acidity), decrease in RBC (beware of hemorrhages/delayed vessel rupture)
Treatment
• ABCs, primary and secondary survey, treat associated injuries
• beware of cardiac arrhythmias (need to keep for monitoring)
• monitor: cardiac arrhythmia, hemochromogenaemia, compartment syndrome, urine output
• wound management: topical agent with good penetrating ability (silver sulfadiazine or mafenide acetate)
• debride non-viable tissue early and repeat prn (every 48 h) to prevent sepsis
• amputations frequently required

| Vascular Status | Allen’s Test |
| Radial and ulnar arteries | Capillary refill (<2-3 s) |
| Digital arteries | For each test, need to compare both sides |
| Temperature and skin turgor | Allen’s Test |

Sensory (refer to Figure 4)

| Median nerve | Dorsal radial tip of index finger |
| Ulnar nerve | Dorsal ulnar tip of little finger |
| Radial nerve | Dorsal web space of the thumb |
| Digital nerves | 2 point discrimination of each finger |

Motor Function

| Median nerve | Extrinsic muscles: flex DIP of index finger ("OK sign"). Intrinsic muscles: thumb to ceiling with palm up |
| Ulnar nerve | Extrinsic muscles: flex DIP of little finger. Intrinsic muscles: abduct index finger ("Peace sign") or patient able to hold piece of paper between adducted fingers and resist pulling |
| Radial nerve | Extrinsic muscles: extend thumb ("thumb’s up") and wrist |

Range of Motion

| Tendons, bones, joints, nerves | Assess active and passive range of motion of wrist extension/flexion/ulnar/radial deviation, finger abduction/adduction/flexion/extension, thumb flexion/extension/arduction/adduction/circumflexion |

General Management

Nerves
• test the nerve function BEFORE putting in local anesthesia
• direct repair for a clean injury within 14 d and without concurrent major injuries → otherwise secondary repair
• epineural repair of digital nerves with minimal tension
• post-operative: dress wound, elevate hand and immobilize
• Tinel's sign (cutaneous percussion over the repaired nerve) produces paresthesias and defines level of nerve regeneration
  ▪ Wallerian degeneration occurs in the first 2 wk, which is why there is no Tinel's sign till after this time period
  ▪ a peripheral nerve regenerates at 1 mm/d
  ▪ paresthesias felt at area of percussion because re-growth of myelin (Schwann cells) is slower than axonal re-growth → percussion on exposed free-end of axon generates paresthesia

Vessels
• often associated with nerve injury (anatomical proximity)
• control bleeding with direct pressure and hand elevation
• if digit devascularized, optimal repair within 6 h
• dress, immobilize, and splint hand with finger tips visible
• monitor color, capillary refill, skin turgor, fingertip temperature post-revascularization

Tendons
• most tendon lacerations require primary repair
• many extensors are repaired in the emergency room, flexors are repaired in the operating room within 2 wk
• avoid excessive immobilization (specific protocols for flexors, 2-3 wk for extensors) to minimize stiffness and facilitate rehabilitation

Bones
• see Fractures and Dislocations, PL25

Nailbed
• remove nail to examine underlying nailbed under digital block anesthesia
• irrigate wound and nail thoroughly
• suture repair of nailbed with catgut suture
• replace cleaned nail, which acts as splint for any underlying distal phalangeal fracture and prevents adhesion formation between nail fold and nailbed

Hand Infections

Principles
• trauma is most common cause
• 5 cardinal signs: rubor (red), calor (hot), tumor (swollen), dolor (painful) and functio laesa (loss of function)
• 90% caused by Gram-positive organisms
• most common organisms (in order) – S. aureus, S. viridans, Group A Streptococcus, S. epidermidis, and Bacteroides melaninogenicus (MRSA is becoming more common)

TYPES OF INFECTIONS

Deep Palmar Space Infections
• uncommon, there are 9 spaces in the hand, the most commonly involved are thenar or mid-palm space (treated in the OR)

Felon
• definition: subcutaneous abscess in the fingertip that commonly occurs following a puncture wound into the pad of digit; may be associated with osteomyelitis (akin to compartment syndrome and can lead to skin necrosis
• treatment: elevation, warm soaks, cloxacillin 500 mg PO q6h (if in early stage); if obvious abscess then I&D, cultures/gram stain, PO cloxacillin

Flexor Tendon Sheath Infection
• Staphylococcus > Streptococcus > Gram-negative rods
• definition: acute suppurative tenosynovitis commonly caused by a penetrating injury and can lead to tendon necrosis and rupture if not treated
• clinical features: Kanavel's 4 cardinal signs
  1. point tenderness along flexor tendon sheath (earliest and the most important)
2. severe pain on passive extension of DIP (second most important)
3. fusiform swelling of entire digit
4. flexed posture (increased comfort)

**treatment**
- OR incision and drainage, irrigation, IV antibiotics, and resting hand splint until infection resolves

**Herpetic Whitlow**
- HSV-1, HSV-2
- **definition:** painful vesicle(s) around fingertip
- often found in medical/dental personnel and children
- **clinical features:** can be associated with fever, malaise and lymphadenopathy
- patient is infectious until lesion has completely healed
- **treatment:** routine culture and viral prep protection (cover), consider oral acyclovir; do not break blisters, as this can spread infection

**Paronychia**
- acute = Staphylococcus; chronic = Candida
- **definition:** infection (granulation tissue) of soft tissue around fingernail (beneath eponychial fold)
- **etiology**
  - acute paronychia: a “hangnail”, artificial nails, and nail biting
  - chronic paronychia: prolonged exposure to moisture
- **treatment**
  - acute paronychia: warm compresses and cephalixin 500 mg PO q6h if caught early and drainage if abscess present – can usually drain with a #11 blade directed into the abscess from underneath the paronychial fold
  - chronic paronychia: anti-fungals with possible debridement and marsupialization, removal of nail plate

**Amputations**

**Hand or Finger**
- emergency management: injured patient and amputated part require attention
  - **patient:** x-rays, NPO, clean wound and irrigate with NS, dress stump with nonadherent, cover with dry sterile dressing, tetanus and antibiotic prophylaxis (cephalosporin/erythromycin)
  - **amputated part:** x-rays, gently irrigate with RL, wrap amputated part in a NS/RL soaked sterile gauze and place inside waterproof plastic bag, place in a container, then place container on ice
- **indications for replantation**
  - **age:** children often better results than adults
  - **level of injury:** proximal, thumb and multiple digit amputations are higher priority
  - **nature of injury:** clean cut injuries have higher successful replantation rate; avulsion and crush injuries are relative contraindications to replant
- if replant contraindicated manage stump with revision amputation
  - would only allow a fingertip injury to heal by secondary intention

**Tendons**

**Common Extensor Tendon Deformities**

<table>
<thead>
<tr>
<th>Table 21. Extensor Tendon Deformities</th>

<tr>
<td>Boutonniere Deformity</td>
</tr>
<tr>
<td>Swan Neck Deformity</td>
</tr>
</tbody>
</table>

Figure 24. Zone of extensor tendon injury (odd numbered zones fall over a joint)

Figure 25. Mallet finger deformity

Figure 26. Boutonniere deformity

Figure 27. Swan neck deformity
De Quervain’s Tenosynovitis (zone 7; most common cause of radial wrist pain)
• definition: inflammation in 1st extensor compartment (APL and EPB)
• clinical features
  • +ve Finkelstein’s test (pain over the radial styloid induced by making fist, with thumb in palm, and ulnar deviation of wrist)
  • pain localized to the 1st extensor compartment
  • tenderness and crepitation over radial styloid may be present
  • differentiate from CMC joint arthritis (CMC joint arthritis will have a positive grind test, whereby crepitus and pain are elicited by axial pressure to the thumb)
• treatment
  • mild: NSAIDs, splinting and steroid injection into the tendon sheath (successful in over 60% of cases)
  • severe: surgical release of stenotic tendon sheaths (APL and EPB); remember there may be 2 or more sheaths

Ganglion Cyst (zone 7)
• definition
  • fluid-filled synovial lining that protrudes between carpal bones or from a tendon sheath; most commonly carpal in origin
  • most common soft tissue tumor of hand and wrist (60% of masses)
• clinical features
  • most common around scapholunate ligament junction
  • 3 times more common in women than in men
  • more common in younger individuals
  • can be large or small – may drain internally so size may wax and wane
  • often non-tender although tenderness increased when cyst smaller (from increased pressure within smaller cyst sac)
• treatment
  • conservative treatment: watch and wait
  • aspiration (recurrence rate 65%)
  • consider operative excision of cyst and stalk (recurrence is possible)
  • steroids if painful

Common Flexor Tendon Deformities
• flexor tendon zones (important for prognosis of tendon lacerations)
• “no-man’s land”
  • between distal palmar crease and mid-middle phalanx
  • zone where superficialis and profundus lie ensheathed together
  • recovery of glide very difficult after injury

Stenosing Tenosynovitis (trigger finger/thumb)
• definition: inflammation of synovium causes size discrepancy between tendon and sheath/pulley (most commonly at A-1 pulley) = locking of thumb or finger in flexion/extension
• etiology: idiopathic or associated with RA, DM, hypothyroidism and gout
• clinical features
  • thumb, ring and long fingers most commonly affected
  • patient complains of catching, snapping or locking of affected finger
  • tenderness to palpation/nodule at palmar aspect of MCP over A-1 pulley
  • women are 4 times more likely than men to be affected
• conservative treatment
  • NSAIDs
  • steroid injection
  • surgical flexor tendon release
  • injections less likely to be successful in patients with DM or symptoms greater than 6 mo
• surgical treatment
  • incise A-1 flexor tendon pulley to permit unrestricted, full active finger motion

Fractures and Dislocations
• for fracture principles, see Orthopedics, OR5

FRACTURES
• about 90% of hand fractures are stable in flexion (lock/prevent extension)
• position of function (like a hand holding a pop can)
  • wrist extension 15°
  • MCP flexion 45°
  • IP flexion (slight)
  • thumb abduction/rotation
  • contraindications: post repair of flexor tendons, median/ulnar nerve injury
• **Position of Safety**
  - Wrist extension 45° (position most beneficial for hand function if immobilized)
  - MCP flexion 60° (maximal collateral ligament stretch)
  -PIP and DIP in full extension (maximal volar plate origin stretch)
  - Thumb abduction and opposition (functional position)
  - Stiffness secondary to immobilization is the most important complication; Tx = early motion

**Distal Phalangeal Fractures**
- Most commonly fractured bone in the hand
- Usual mechanism is crush injury and thus accompanied by soft tissue injury
- Subungual hematoma is common and must be decompressed if painful or nail removed
- Treatment consists of 3 wk of digital splinting (with IP joint movement preserved)

**Proximal and Middle Phalangeal Fractures**
- Check for: rotation, scissoring (overlap of fingers on making a fist), shortening of digit
- Undisplaced or minimally displaced: closed reduction (if extra-articular) buddy tape to neighboring stable digit, elevate hand, motion in guarded fashion early, splinted for 2-3 wk
- Displaced, non-reducible, not stable with closed reduction, or rotational or scissoring deformity: percutaneous pins (K-wires) or ORIF, and splint

**Metacarpal Fractures**
- Generally accept varying degrees of deviation before reduction required: up to 10° (D2), 20° (D3), 30° (D4), or 40° (D5)
- **Boxer's Fracture (Extra-Articular):** acute angulation of neck of metacarpal of little finger into palm
  - Mechanism: blow on the distal-dorsal aspect of closed fist
  - Loss of prominence of metacarpal head, volar displacement of head
  - Check for scissoring of fingers on making a fist
  - Up to 30-40° angulation may be acceptable
  - Closed reduction should be considered to decrease the angle
  - If stable ulnar gutter splint for 2-3 wk with PIP and DIP free
- **Bennet's Fracture (Intra-Articular):** fracture/dislocation of the base of the thumb metacarpal
  - Unstable fracture
  - Abductor pollicis longus pulls MC shaft proximally and radially causing adduction of thumb
  - Treat with percutaneous pinning, thumb spica x 6 wk
- **Rolando's Fracture (Intra-Articular):** T- or Y-shaped fracture of the base of the thumb metacarpal
  - Treat with ORIF with K-wire

**Dislocations**
- Must be reduced as soon as possible
- Dislocation vs. subluxation
  - Dislocation: severe injury where articular surfaces of a joint are no longer in contact with one another
  - Subluxation: articular surfaces of a joint are partially out of place, but then go back into place (partial dislocation)

**PIP and DIP Dislocations**
- PIP more common than DIP
- Usually dorsal dislocation (commonly from hyperextension)
- If closed dislocation: closed reduction and splinting (30° flexion for PIP and full extension for DIP) or buddy taping and early mobilization (prolonged immobilization causes stiffness)
- Open injuries are treated with wound care, closed or open reduction and antibiotics

**MCP Dislocations**
- Relatively rare
- Dorsal dislocations much more common than volar dislocations
- Dorsal dislocation of proximal phalanx on metacarpal head; most commonly index finger (hyperextension)
- Two types of dorsal dislocation
  - Simple (reducible with manipulation): treat with 2-4 wk of splinting at 30° MCP flexion
  - Complex (volar plate blocks reduction): treat with open reduction and A1 pulley release + extension-blocking splint at 30° flexion (2 wk) then 10° flexion (2 wk)

**Ulnar Collateral Ligament (UCL) Injury**
- Forced abduction of thumb (e.g. ski pole injury)
- **Skier's Thumb:** acute UCL injury
- **Gamekeeper's Thumb:** chronic UCL injury
- Evaluation: radially deviate joint in full extension and at 30° flexion and compare with non-injured hand. UCL rupture is presumed if injured side deviates more than 30° in full extension or more than 15° in flexion.
- **Stener's Lesion:** the UCL has bony attachments to the adductor aponeurosis and the proximal ligament can displace while the distal attachment remains deep to the aponeurosis, forming a barrier that blocks healing and leads to chronic instability; requires surgery
Dupuytren’s Disease

**Definition**
- contraction of longitudinal palmar fascia, forming nodules (usually painless), fibrous cords and eventually flexion contractures at the MCP and interphalangeal joints
- flexor tendons not involved
- Dupuytren's diathesis: early age of onset, strong family history, and involvement of sites other than palmar aspect of hand

**Epidemiology**
- genetic disorder, unusual in patients from African and Asian countries, high incidence in northern Europeans, men > women, often presents in 5th-7th decade of life, associated with but not caused by alcohol use and DM

**Clinical Features**
- order of digit involvement (most common to least common): ring > little > long > thumb > index
- may also involve feet (Ledderhose's) and penis (Peyronie's – see Urology, U29)

**Treatment**
- stages
  1. palmar pit or nodule: no surgery
  2. palpable band/cord with no limitation of extension of either MCP or PIP: no surgery
  3. lack of extension at MCP or PIP: surgical fasciectomy indicated
  4. irreversible periarticular joint changes/scarring: surgical treatment possible but poorer prognosis compared to stage 3
- indications for percutaneous release
  - functional impairment
  - MCP contractures >30°
  - any PIP contracture
  - rapidly progressive disease
- may recur, especially in Dupuytren's diathesis

Carpal Tunnel Syndrome

**Definition**
- median nerve compression at the level of the flexor retinaculum as opposed to pronator teres syndrome

**Etiology**
- median nerve entrapment at wrist
- primary cause is idiopathic
- secondary causes: space occupying lesions (tumors, hypertrophic synovial tissue, fracture callus, and osteophytes), metabolic and physiological (pregnancy, hypothyroidism, acromegaly, and RA), infections, neuropathies (associated with DM or alcoholism), and familial disorders
- job/hobby related repetitive trauma, especially forced wrist flexion

**Epidemiology**
- female:male = 4:1, most common entrapment neuropathy

**Clinical Features**
- sensory loss in median nerve distribution i.e. radial 3.5 digits (see Figure 4)
- discriminative touch often lost first
- classically, patient awakened at night with numb/painful hand, relieved by shaking/dangling/rubbing
- decreased light touch and 2-point discrimination, especially fingertips
- ± Tinel's sign (tingling sensation on percussion of nerve)
- ± Phalen's sign (wrist flexion induces symptoms)

**Investigations**
- clinical diagnosis
- NCV and EMG may confirm, but do not exclude, the diagnosis

**Treatment**
- avoid repetitive wrist and hand motion, wrist splints when repetitive wrist motion required
- conservative: night time splinting to keep wrist in neutral position
- medical: NSAIDs, local corticosteroids injection, oral corticosteroids
- surgical decompression: transverse carpal ligament incision to decompress median nerve
- indications for surgery: numbness and tingling ± sensory loss, weakness ± muscle atrophy, unresponsive to conservative measures
- complications of surgery; injury to median motor branch, palmar cutaneous branch or superficial transverse vascular arch, local pain (pilar pain), and scar formation

Accuracy of the Clinical Assessment for Carpal Tunnel Syndrome

- Phalen’s: Sensitivity: 0.75 Specificity: 0.47
- Tinel’s: Sensitivity: 0.60 Specificity: 0.67
- Carpal Tunnel Compression Test: Sensitivity: 0.87 Specificity: 0.90

Development and Validation of Diagnostic Criteria for Carpal Tunnel Syndrome

- Purpose: To develop a clinical diagnostic criteria for carpal tunnel syndrome that modeled the clinical diagnostic practices of experts.

- Methods: Out of 57 clinical findings associated with CTS, eight were ranked highly by a panel of expert clinicians. Using 256 case histories, a panel of experts decided whether a case did or did not have a diagnosis of CTS. This diagnosis represented the dependent variable for a logistic regression model, to which the eight clinical findings were applied. The regression model was then validated against the consensus of a second panel on the diagnosis of CTS for the case histories.

- Results/Conclusions: The correlation between the probability of CTS predicted by the regression model and the panel of clinicians was 0.71. Clinical diagnostic criteria that contributed significantly to the model were:
  1. Numbness and tingling in median nerve distribution
  2. Nocturnal numbness
  3. Weakness and/or atrophy of the thenar musculature
  4. Tinel’s sign
  5. Phalen’s test
  6. Loss of 2-point discrimination
Rheumatoid Hand

- see Rheumatology, RH5

Brachial Plexus

Etiology
- common causes of brachial plexus injury: complication of childbirth and trauma
- other causes of injury: compression from tumors, ectopic ribs

Common Palsies

Table 22. Named Neonatal Palsies of the Brachial Plexus

<table>
<thead>
<tr>
<th>Palsy</th>
<th>Location of Injury</th>
<th>Mechanism of Injury</th>
<th>Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>Duchenne-Erb Palsy</td>
<td>Upper brachial plexus (C5-C6)</td>
<td>Head/shoulder distraction (e.g. motorcycle)</td>
<td>Waiter’s tip deformity (shoulder internal rotation, elbow extension, wrist flexion)</td>
</tr>
<tr>
<td>Klumpke’s Palsy</td>
<td>Lower brachial plexus (C7-T1)</td>
<td>Traction on abducted arm</td>
<td>May include Horner’s syndrome (“claw hand”)</td>
</tr>
</tbody>
</table>

Differential Diagnosis
- trauma (blunt, penetrating)
- thoracic outlet syndrome
  - neurogenic: associated with cervical rib; compression of C8/T1
  - vascular: pain or sensory symptoms without cervical rib; cessation of radial pulse with provocative maneuvers
- tumor
  - schwannoma: well-defined margins makes it easier for total resection
  - neurofibromas: associated with neurofibromatosis type I
  - other: e.g. Pancoast syndrome (apical lung tumor)
- neuropathy (compressive, post-irradiation, viral, diabetic, idiopathic)

Investigations
- EMG
- MRI: gold standard for identifying soft tissue masses
- CT myelogram: better than MRI for identification of nerve root avulsion and identification of pseudomeningocoele. Important for pre-operative identification of patients likely to require neurotisation procedures (especially for patients with blunt trauma)

Management

Table 23. Management of Brachial Plexus Injuries

<table>
<thead>

<td>Penetrating Trauma</td>
<td>Sharp or vascular injury Explore immediately in OR</td>
</tr>
</tbody>
</table>

Craniofacial Injuries

- low velocity vs. high velocity injuries determine degree of damage
- fractures cause bruising, swelling and tenderness → loss of function
- frequency: nasal > zygomatic > mandibular > maxillary
- management: can wait 5-10 d for swelling to decrease before ORIF required
Approach to Facial Injuries

- ATLS protocol
- inspect, palpate, clinical assessment for injury to underlying structures (e.g. facial nerve)
- visual assessment
- tetanus prophylaxis
- radiological evaluation
- wound irrigation with NS/RL and remove foreign materials
- conservative debridement of detached or nonviable tissue
- repair when patient's general condition allows (soft tissue injury: <8 h preferable)

Investigations

- CT
  - axial and coronal (specifically request 1.5 mm cuts): for fractures of upper and middle face (not good for mandible)
  - indicated for high velocity trauma, complex facial fractures, orbital floor, panface fractures, pre-operative assessment
- panorex radiograph: shows entire upper and lower jaw; best for isolated mandible fracture as patient must be able to sit

</tbody>
</table>

*Gold standard

Treatment

- consultation when indicated (dentistry, ophthalmology)
- re-establish normal occlusion
- pursue normal eye function
- restore stability of face and appearance

Complications

- diplopia/enophthalmos/blindness
- intracranial pathology such as CSF leak, bleeding and SIADH
- sinusitis
- functional abnormalities (i.e. malocclusion)
- infection – extremely rare
- poor cosmesis; need for 2nd surgery
- septal hematoma and septal necrosis

Mandibular Fractures

- always two points of injury since it is a ring structure (includes fractures and dislocations)
- commonly at sites of weakness (condylar neck, angle of mandible, region of 3rd molar or canine tooth)

Etiology

- anterior force: bilateral fractures
- lateral force: ipsilateral subcondylar and contralateral angle or body fracture
- note: classified as open if fracture into tooth bearing area (alveolus)

Clinical Features

- pain, swelling, difficulty opening mouth ("trismus")
- malocclusion, asymmetry of dental arch
- damaged, loose, or lost teeth
- palpable "step" along mandible
- numbness in V3 distribution
- intra-oral lacerations or hematoma (sublingual)
- chin deviating toward side of a fractured condyle
- bilateral condyle fractures will have anterior open bite
Table 25. Mandibular Fracture Classifications by Anatomic Region (refer to Figure 35)

</tr>
</tbody>
</table>

*Most common mandibular fracture type

Treatment
- maxillary and mandibular arch bars wired together (intramaxillary fixation) or ORIF
- antibiotics to cover against S. aureus and anaerobes

Complications
- malocclusion, malunion
- tooth loss, and possible sensation loss
- TMJ ankylosis

Maxillary Fractures

Nasal Fractures

Etiology
- lateral force → more common, good prognosis
- anterior force ← can produce more serious injuries
- most common facial fracture

Clinical Features
- epistaxis/hemorrhage, deviation/flattening of nose, swelling, periorbital ecchymosis, tenderness over nasal dorsum, crepitus, septal hematoma, respiratory obstruction, subconjunctival hemorrhage
- depression and splaying of nasal bones causing a saddle deformity
- important to clinically assess for naso-orbital ethmoid fractures

Treatment
- in the absence of complications, no treatment required
- closed reduction with Asch or Walsham forceps under anesthesia, pack nostrils with Adaptic®, nasal splint for 7 d
- best reduction immediately (<6 h) or when swelling subsides (5-7 d)
- rhinoplasty may be necessary later for residual deformity (30%)
Naso-Orbital Ethmoid Fractures

Etiology
• fractures of the nasal and ethmoid bones of the medial orbit
• problematic and may lead to greatest change in facial appearance
• Markowitz-Manson classification
  ▪ Type 1: Single, central fragment, medial canthal ligament intact
  ▪ Type 2: Comminuted central fragment, medial canthal ligament intact
  ▪ Type 3: Severe comminution of central fragment and disrupted medial canthal ligament

Clinical Presentation
• telecanthus (increased intercanthal distance secondary to medial canthal ligament disruption)
• orbital rim step-off
• similar to nasal fractures

Treatment
• surgical repair to restore intercanthal distance, nasal projection and orbital anatomy

Zygomatic Fractures

• 3 categories
  1. fracture restricted to zygomatic arch
  2. depressed fracture of zygomatic complex (zygoma)
  3. unstable fracture of zygomatic complex (tetrapod fracture) – separations occur at maxilla, frontal bone, temporal bone and orbital rim

Clinical Features
• flattening of malar prominence (view from above)
• pain over fractures on palpation
• numbness in V2 distribution (infraorbital and superior dental nerves)
• palpable step deformity in bony orbital rim (especially inferiorly)
• often associated with fractures of the orbital floor
• ipsilateral epistaxis; trismus (lock jaw)

Treatment
• if undisplaced, stable and no symptoms, then soft diet; no treatment necessary
• ophthalmologic evaluation if suspected orbital injury
• uncomplicated zygomatic arch fractures can be elevated using Gillies approach: leverage on the anterior part of the zygomatic arch via a temporal incision; stabilization often unnecessary
• ORIF for displaced or unstable fractures of zygomatic complex

Orbital Floor Fractures

• see Ophthalmology, OP43

Definition
• fracture of floor of orbit ± intact infraorbital rim
• may be associated with nasoethmoid fracture

Etiology
• blunt force to eyeball → sudden increase in intra-orbital pressure (e.g. baseball or fist)

Clinical Features
• check visual fields and acuity for injury to globe
• periorbital edema and bruising, subconjunctival hemorrhage
• ptosis, exophthalmos, exorbitism, or enophthalmos
• orbital rim step-offs with possible infraorbital nerve anesthesia
• vertical dystopia (abnormal displacement of the entire orbital cone in the vertical plane); diplopia looking up or down (entrapment of inferior rectus), limited EOM
• orbital entrapment
  ▪ clinical diagnosis that is a surgical emergency
  ▪ diplopia with vertical gaze; limited EOM
  ▪ severe pain or nausea and vomiting with eye movement
  ▪ requires urgent ophthalmology evaluation and surgical repair
Investigations
• CT (diagnostic): axial and coronal views
• diagnostic manoeuvre for entrapment is forced duction test (pulling on inferior rectus muscle with forceps to ensure full ROM) under anesthesia

Treatment
• surgical repair indicated if: urgent repair for entrapment, floor defect >1 cm, any size defect with enophthalmos or persistent diplopia (>10 d)
• reconstruction of orbital floor with bone graft or alloplastic material
• ophthalmologic evaluation suggested

Complications
• persistent diplopia
• enophthalmos

Superior Orbital Fissure Syndrome
• fracture of SOF causing ptosis, proptosis, anesthesia in V1 distribution, and painful ophthalmoplegia (paralysis of CN III, IV, VI)
• uncommon complication seen in Le Fort II and III fractures (1/130)
• recovery time reported as 4.8-23 wk following operative reduction of fractures

Orbital Apex Syndrome
• fracture through optic canal with involvement of CN II at apex of orbit
• symptoms are the same as SOF syndrome plus vision loss
• treatment is urgent decompression of fracture in optic canal or steroids (emergency)

Breast Surgery
Breast Reconstruction
• integral part of breast cancer treatment
• two basic methods: implants (1-stage or 2-stage) or autologous tissue
• may also require breast balancing procedure and nipple areola reconstruction

Pre-Reconstruction Considerations
• radiation: treatment before and after mastectomy is a relative contraindication to alloplastic reconstruction
• recipient tissue: skin sparing mastectomy allows for the use of implants without tissue expanders (1-stage process)
• donor tissue: limited availability of suitable donor tissue (lack of tissue, scar, previous surgery that interferes with blood supply) may prevent the use of autologous tissue reconstruction
• timing (immediate vs. delayed)
• contralateral breast: may not be possible to reconstruct a breast of the same size or shape as the contralateral breast. Breast reduction or mastopexy may be considered in opposite breast (see Table 28)
• other considerations: patient's age and comorbidities, prognosis, body weight, characteristics of chest wall and patient's attitude

Table 27. Options for Breast Reconstruction

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Definition</th>
<th>Surgical Details</th>
<th>Other Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alloplastic (Implant based)</td>
<td>Use of synthetic material (silicone or saline implants)</td>
<td>With expanders (2 stages): Use tissue expanders before replacement with implants to help facilitate breast ptosis&lt;br&gt;Without expanders (1 stage): In skin-sparing mastectomy, enough skin is available for immediate placement of implant (may require acellular dermal matrix if implant size and muscle size is a mismatch)</td>
<td>Complications: capsular contraction (foreign body reaction to implants), rupture or leakage of implant, increased risk of infection, 35% revision rate over 5 yr</td>
</tr>
<tr>
<td>Autologous Tissue</td>
<td>Use of patient’s own tissue</td>
<td>Many flap options: DIEP, TRAM, latissimus donsi, SIEA, SGAP, and IGAP</td>
<td>Offers reduced long-term morbidity and natural consistency</td>
</tr>
<tr>
<td>Nipple Areola Reconstruction</td>
<td>Final stage of breast reconstruction</td>
<td>Usually require tattooing for areola reconstruction&lt;br&gt;Local vs. distant flap/graft: 1. Local: fish tail or skate flap most common; these flaps allow simultaneous nipple and areola reconstruction&lt;br&gt;2. Distant: opposite nipple, earlobe, abdominal skin, costal cartilage, labia</td>
<td>Usually performed 3 mo post-reconstruction</td>
</tr>
</tbody>
</table>

Diplopia can present late in orbital blow-out fractures

Patients may require a balancing procedure on contralateral side
Breast Tissue Expanders
- placement: sub-pectoral, total submuscular (pectoral/serratus)
- size: depends on contralateral breast and desired size
  - generally over-expanded to facilitate ptosis
- timing of expansion: begins when wound fully healed (usually 2 wk post-operative), and implants are expanded weekly or bi-weekly until complete (up to 3 mo); expanders are exchanged for implants after another 3 mo for consolidation of expanded skin

Arterial blood supply to the breast
- internal thoracic*
- external thoracic*
- lateral thoracic
  - thoracoacromial
  - intercostals
  - thoracodorsal
* also provide arterial blood supply to nipple-areola complex

Pedicle Designs
- inferior pedicle technique
- superior pedicle
- central pedicle/mound
- medial pedicle

Breast Reduction
- reduction mammoplasty performed for relief of physical symptoms (e.g. shoulder groove, neck pain, back pain, shoulder pain, mastodynia), and to improve breast size and shape
- key steps of procedure
  - incisions: circular around the areola, vertical from areola incision to infra-mammary fold, along the natural infra-mammary fold
  - removal of fat, breast tissue, and excess skin
  - possible need to move nipple and areola complex to higher position
- complications: infection, hemorrhage, decreased nipple sensation, inability to breast feed, breast/nipple asymmetry, nipple loss (partial or complete), skin loss/necrosis, fat necrosis

BMJ 2013;346:f2399
Purpose: To determine if breast augmentation for cosmetic purposes affects stage at diagnosis and post-diagnosis survival compared with women with no implants.
Methods: Systematic review of observational studies with two meta-analyses.
Results: Meta-analysis examining breast CA stage: odds ratio 1.26 for non-localized stage breast CA at diagnosis comparing women with and without implants (12 studies, 95% CI 0.99-1.6; p=0.058).
Meta-analysis examining post-diagnosis survival: reduced survival after breast CA among women with implants compared with women without implants (5 studies, hazard ratio for breast CA specific mortality 1.38, CI 1.08-1.75).
Conclusions: Although findings need to be interpreted with caution, research published to date suggests that cosmetic breast augmentation may adversely affect survival of women subsequently diagnosed with breast CA.
# Aesthetic Surgery

## Aesthetic Procedures

<tr>
<th>Definition</th>
<th>Epidemiology</th>
<th>Clinical Features</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cleft Lip</td>
<td>Failure of fusion of maxillary and medial nasal processes. M:F = 2:1</td>
<td>Classified as incomplete/complete and uni/bilateral 2/3 cases: unilateral, left-sided, male.</td>
<td>Surgery (3 mo): Millard, Tennison-Randall, or Fisher subunit repair corrections usually required later on (especially for nasal deformity).</td>
</tr>
<tr>
<td>Cleft Palate</td>
<td>Failure of fusion of lateral palatine/median palatine processes and nasal septum. Isolated cleft palate: 0.5 per 1,000 (no racial variation). F&gt;M</td>
<td>Classified as incomplete/complete and uni/bilateral. Isolated (common in females) or in conjunction with cleft lip (common in males).</td>
<td>Special bottles for feeding. Speech pathologist. Surgery (6-9 mo): Von Langenbeck or Furlow Z-Plasty. ENT consult — often recurrent otitis media, requiring myringotomy tubes.</td>
</tr>
<tr>
<td>Craniosynostosis</td>
<td>Premature fusion of ≥1 cranial sutures. Primary — abnormal suture, no known cause. This may limit brain growth perpendicular to the suture and cause compensatory growth parallel to the fused suture. 1 in 2,000 live newborns; M:F = 52:48. Syndromes include: Crouzon’s, Apert’s, Saethre-Chotzen, Carpenter’s, Pfeiffer’s-Jackson-Weiss and Boston-type syndromes.</td>
<td>Syndromic — associated with genetic mutation. Secondary (to microcephaly, hypothyroid, rickets, etc.). Dx: irregular head shape, craniofacial abnormalities, x-ray.</td>
<td>Multidisciplinary team (including neurosurgery, ENT, genetics, dentistry, pediatrics, SLP). Early surgery prevents secondary deformities. ICP is an indication for emergent surgery. ICU bed may be required post-surgically.</td>
</tr>
</tbody>
</table>

Historical Context of Public Health

- see *Ethical, Legal, and Organizational Medicine*, ELOAM2 for Legal Foundation

**Definitions**

- **population health**
  - health of the population as measured by health status indicators (e.g. life expectancy, low birth weight rates)
  - influenced by: physical, biological, social, environmental, and economic factors; personal health behaviors; health care services
  - refers to the prevailing or desired level of health in the population of a specific country/region/subset of population
  - considered to be more complex than the aggregate health status of individuals within a population

- **public health**
  - organized collective efforts of society to protect, promote, and restore the health of the public and prevent illness, injury, and premature death
  - refers to the practices, programs, policies, institutions, and disciplines required to achieve the desired state of population health

- **public health and preventive medicine** (formerly called community medicine)
  - the postgraduate study of health and disease in the population or a specified community
  - goal: to identify and address health problems and evaluate the extent to which health services and others address these issues

**Determinants of Health**

- **wellness**: state of dynamic physical, mental, social, and spiritual well-being that enables a person to achieve full potential and have an enjoyable life
- **disease**: abnormal, medically-defined changes in the structure or function of the human body
- **illness**: an individual's experience or subjective perception of a lack of physical or mental well-being and consequent inability to function normally in social roles
- **illness behavior**: an individual's actions in response to their illness, including whether they seek health care and whether they comply with the subsequent recommendations
- **sickness**: socially and culturally held conceptions of health conditions that may influence how the patient reacts
- **impairment**: any loss or abnormality of psychological, physiological, or anatomical structure or function
- **disability**: any restriction or lack of ability to perform an activity within the range considered normal for a human being
- **handicap**: the disadvantage for an individual arising due to impairment and disability
  - limits or prevents the fulfillment of an individual's normal role as determined by society and depends on age, sex, social, and cultural factors
  - changes the individual's relationship with the physical and social environment
- **health equity**: when all people have "the opportunity to attain their full health potential" and no one is "disadvantaged from achieving this potential because of their social position or other socially determined circumstance." Differs from health equality. Health inequities are those which are considered unjust and/or avoidable
- **health equality**: defined as where populations have equal or similar health status. Health inequalities are systematic differences in health status that occur among population groups...

Definitions of Health
- First multidimensional definition of health, as defined by the WHO in 1948: “state of complete physical, mental and social well-being and not merely the absence of disease or infirmity”
- WHO updated the definition (socio-ecological definition) of health in 1986: “The ability to identify and to realize aspirations, to satisfy needs, and to change or cope with the environment. Health is therefore a resource for everyday life, not the objective of living. Health is a positive concept emphasizing social and personal resources, as well as physical capacities” (Ottawa Charter for Health Promotion)
- Other definitions of health have since been proposed that incorporate other dimensions of health (e.g. “Health is a social, economic, and political issue and above all a fundamental human right” – The People’s Charter for Health)

<td></td>
<td></td>
</tr>
</tbody>
</table>

Note: this chart delineates the major challenges faced by each group, but the issues listed are not unique to each population

**Disease Prevention**

**Disease Prevention Strategies**
- measures aimed at preventing the occurrence, interrupting through early detection and treatment, or slowing the progression of disease/mitigating the sequelae

**Primary Prevention**
- implemented to prevent disease from occurring
- immunization programs exist in most countries to address major causes of pediatric morbidity and mortality that are preventable by vaccines, e.g. measles, diphtheria, pertussis, tetanus, polio, and tuberculosis (not routine in the U.S.)
- additional immunizations are offered in US depending on jurisdiction: mumps, rubella, rotavirus, hepatitis B, *Haemophilus influenzae* type B, varicella, HPV, conjugated pneumococcal and meningococcal vaccines (see *Pediatrics, P3*).

**Secondary Prevention (Screening)**
- presumptive identification (not diagnosis) of unrecognized disease or defect by the application of tests, examinations, or other procedures which can be applied rapidly
- types of screening
  - mass screening: screening all members of a population for a disease (e.g. phenylketonuria (PKU) and hypothyroidism in all newborns)
  - selective screening: screening of a specific subgroup of the population at risk for a disease (e.g. mammography in women >50 yr old)
  - multiphasic screening: the use of many measurements and investigations to look for many disease entities (e.g. periodic health exam)

**Tertiary Prevention**
- treatment and rehabilitation of disease after it has been diagnosed so as to prevent progression and permanent disability (e.g. HbA1c, eye, and foot monitoring for diabetes)

**Table 2. Ideal Criteria for Screening Tests**

<table>
<thead>
<tr>
<th>Disease</th>
<th>Test</th>
<th>Health Care System</th>
</tr>
</thead>
<tbody>
<tr>
<td>Causes significant suffering and/or death</td>
<td>High specificity and sensitivity, Safe, rapid, easy, relatively inexpensive, Acceptable to providers and to population</td>
<td>Adequate capacity for reporting, follow-up, and treatment of positive screens, Cost effective, Sustainable program, Clear policy guidelines</td>
</tr>
<tr>
<td>Natural history must be understood</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Must have an asymptomatic stage that can be detected by a test</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Early detection and intervention must result in improved outcomes</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Incidence is not too high or too low</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Disease Prevention Strategies**
- **Primary**: before disease occurs (e.g. immunizations, seatbelt use, smoking cessation programs for lung cancer prevention)
- **Secondary**: early detection of disease (e.g. mammography, routine Pap smears)
- **Tertiary**: treatment and rehabilitation of existing disease (e.g. ACE inhibitor for HTN)

Within these three stages of prevention there can be both:
- **Passive prevention**: measures that operate without the person’s active involvement (e.g. airbags in cars)
- **Active prevention**: measures that a person must do on their own (e.g. wearing a seatbelt)
**Health Promotion Strategies**

**Table 3. Disease Prevention vs. Health Promotion Approach**

**Healthy Public Policy**

- characterized by an explicit concern for health and equity in all areas of policy and by an accountability for health impact
- main aim: to create a supportive environment to enable people to lead healthy lives, thereby making healthy choices easier for citizens
- government sectors must take into account health as an essential factor when formulating policy and should be accountable for the health consequences of their policy decisions
- methods
  - fiscal: imposing additional costs (e.g. taxes on tobacco and alcohol)
  - legislative: implementing legal deterrents (e.g. smoking bans, legal alcohol drinking age)
  - social: improving health beyond providing universally funded health care (e.g. providing affordable housing)

*Source: International Conference on Health Promotion, Adelaide, South Australia (1998)*

**Behavior Change**

- health education serves to
  - increase knowledge and skills
  - encourage positive behavior changes and discourage unhealthy choices
- health education is an important component of eliciting behavior change
- behavior is a result of three factors
  1. predisposing factors: knowledge, attitude, beliefs, values, intentions
  2. enabling factors: skills, supports
  3. reinforcing factors: health care professionals and the social context of family and community
- **Health Belief Model (1975)**
  - behaviors undertaken by individuals in order to remain healthy are a function of a set of interacting beliefs
  - beliefs include an individual’s perception of his or her susceptibility to a disease, the severity of the disease, and the benefits and costs of health-related actions
  - beliefs are modified by socio-demographic and psychosocial variables
  - individuals must believe that the action will have positive consequences
  - individuals must be in a state of readiness
  - behavior can be stimulated by cues to action, which are specific events that can encourage preventive health decisions and actions (e.g. physician recommendation, public advertising)
- **Stages of Change Model**
  - provides a framework in which the Health Belief Model is applied to facilitating behavior change (e.g. quitting smoking)

**Jakarta Declaration on Health Promotion into the 21st Century (WHO 1997)**

- Reinforced the commitment to health promotion
- First of the health promotion conferences to involve the private sector
- Formally cited poverty as the greatest threat to health
- Priorities for health promotion:
  - Promote social responsibility for health
  - Increase investments for health development
  - Consolidate and expand partnerships for health
  - Increase community capacity and empower the individual
  - Secure an infrastructure for health promotion
Life Expectancy
- the expected number of years that an individual will live based on standardized death rates for the population
- usually qualified by country, gender, and age

Crude Death Rate
- mortality rate from all causes of death per 1,000 in the population

Age Standardized Rate
- adjustment of the crude rate of a health-related event using a “standard” population
- standard population is one with a known number of persons in each age and sex group
- standardization prevents bias which could be made by comparing crude rates from two dissimilar populations (e.g. crude death rates over a number of decades are not comparable as the population age distribution has changed with time)

Standardized Mortality Rate
- the ratio of the observed (actual) number of deaths to the expected number of deaths for a group (e.g. age, race, gender, etc.)
- useful for comparing populations that are significantly different in some aspect (e.g. the causes of death in more and less developed countries)

Infant Mortality Rate (IMR)
- number of deaths among children under 1 yr of age reported during a given time period divided by the number of live births reported during the same time period and expressed per 1,000 live births per year

Maternal Mortality Rate (MMR)
- number of deaths of women during pregnancy and due to puerperal causes per 100,000 live births per year

Proportional Mortality Ratio (PMR)
- proportion of all deaths in a specified population over a given period of time attributable to a specific cause
  - each cause is expressed as a percentage of all deaths, with the sum of all causes adding to 100%

Potential Years of Life Lost (PYLL)
- calculated for a population using the difference between the actual age at death and a standard/expected age at death
- increased weighting of mortality at a younger age

Risk Reduction Strategies
- risk reduction: lower the risk to health without eliminating it (e.g. avoiding sun to lower risk of skin cancer)
- harm reduction: tolerance of some degree of risk behavior, while aiming to minimize the adverse outcomes associated with these behaviors (e.g. needle exchange programs)

Measurements of Health and Disease in a Population

Example of Harm Reduction Strategy

Summary of Findings from the Evaluation of a Pilot Medically Supervised Safer Injecting Facility
CMAJ 2006;175:1399-1404

Background: This study discusses the outcomes among a population of illicit injection drug users (IDUs) after initiating a supervised safer injecting facility in Vancouver, September 2003. Legal exemption by the Canadian government was granted such that an evaluation of its results be conducted over a 3 yr period.

Study Population: IDUs of the Vancouver area were allowed to inject previously obtained illicit drugs under the supervision of nurses and physicians. IDUs were offered addiction counseling and supports for appropriate community resources. A random sample of 670 IDUs was recruited and monitored from Dec 2003-July 2004.

Results: Characteristics of IDUs who used the safe injecting facility included age <30 yr, history of drug use, homelessness, daily heroin and/or cocaine injection, and recent history of overdose. Mean measures of public order problems were taken 6 wk before and 12 wk after initiation of the safer injecting facility. It was found that the mean number of IDUs injecting daily in public, along with the mean number of publically discarded syringes were reduced by approximately half.

Conclusions: Overall it has been found that the safer injecting facility in Vancouver has been successful in attracting IDUs at increased risk of HIV, overdose, and public injection of substances. This has resulted in lower incidences of public drug use, publicly discarded syringes and sharing of needles. Other studies associated with this one have demonstrated that there has been no increase in the drug dealing, drug related crimes, or rates of new IDUs in the area surrounding the safer injecting facility.

Principles of Standardization
- When comparing an outcome (e.g. mortality) in two populations that differ in terms of characteristics known to influence that outcome (e.g. age), standardization is used to control for the effect of that factor
- Standardization is either direct or indirect:
  - Indirect standardization: expressed as standardized outcome ratio. For example a standardized mortality ratio (SMR) is calculated using age specific rates for a reference population as well as age structure and total cases for a sample/know population e.g. A SMR of 100 signifies that deaths are at the expected level, a SMR of 110 indicates a death rate 10% higher than expected
  - Direct standardization: expressed as a rate: using age specific rates in a known/sample population against a standard population
Disability Adjusted Life Year (DALY)
• quantitative indicator of the burden of diseases that reflects the total amount of disability-free life years lost
• includes loss from premature mortality and loss due to a degree of disability over a specific period of time; these disabilities can be physical or mental

Quality Adjusted Life Year (QALY)
• a value from 0 to 1 assigned to a year of life based on perceived quality of life; a year in “perfect” health is considered equal to 1 QALY, the value of a year in ill health would be lowered based on the burden of disease
• it is possible to have “states worse than death” for example QALY <0 for extremely serious conditions

Epidemiology

Population
• a collection of individuals who share a common trait (most commonly applied to a geographic area but it could be another factor such as ethnic group)

Sample
• a selection of individuals from a population or set of observations
• types
  • random: all are equally likely to be selected
  • systematic: an algorithm is used to select a subset
  • stratified: separate representations of more than one subgroup
  • cluster: grouped in space/time to reduce costs
  • convenience: non-random inclusion, usually volunteers

Sample Size
• sample size contributes to the statistical precision of the observed estimate
• increasing the sample size decreases the probability of type I and type II errors

Bias
• non-random error leading to a deviation of inferences or results from the truth
• any trend in the collection, analysis, interpretation, publication, or review of data that can lead to conclusions that are systematically different from the truth
  • lead-time: time between early diagnosis with screening, and when diagnosis would have been made without screening
  • lead-time bias: over-estimation of survival when the estimate is made from the time of screening, instead of the later time when the disease would have been diagnosed without screening
  • incidence-prevalence bias: when prevalent cases include long-term survivors who have a better prognosis than some incident cases
  • length-time bias: overestimation of the survival time due to the sampling of prevalent as opposed to incident cases
    • selection of prevalent cases will favor the over-inclusion of longer-living cases rather than newly-diagnosed incident cases, some of whom may have short survival times
  • sampling bias: occurs with the selection of a sample that does not truly represent the population
    • sampling procedures should be chosen to prevent or minimize bias
  • recall bias: when individuals with a disease are more prone to recalling or believing they were exposed to a possible causal factor than those who are free of disease

Incidence and Prevalence

Incidence = \( \frac{\text{# of new cases in a time interval}}{\text{total population at risk}} \)
(measures the rate of new infections)

Prevalence = \( \frac{\text{# of existing cases at a point in time}}{\text{total population at risk}} \)
(measures the frequency of disease at a point in time)

Figure 3. Lead time bias

Confounder
• a variable that is related to both the exposure and outcome but is not measured or is not distributed equally between groups
• distorts the apparent effect of an exposure or risk because it may not be possible to separate/control for the contribution of a single causal factor to an effect (e.g. late maternal age could be a confounder in an investigation of birth order >4 and risk of developing Trisomy 21)
**Prevalence**
- total number of cases in a population over a defined period of time
- two forms of prevalence
  - point prevalence: attempts to measure the frequency of all disease at one specific point in time, therefore knowledge of the time of onset of disease is not required
  - period prevalence: measure constructed from prevalence at a point in time, plus new cases and recurrences over a defined period of time
- depends on incidence rate and disease duration from onset to termination (cure or death)
- favors the inclusion of chronic over acute cases and may be used to present a biased picture of the disease
- prevalence studies are cross-sectional and cannot be used for causal inferences
- prevalence figures are useful for determining the extent of a disease and can aid in the rational planning of facilities and services

**Sensitivity**
- proportion of people with disease who are correctly identified by having a positive test

**Specificity**
- proportion of people without disease who are correctly identified by having a negative test

**Pre-Test Probability**
- an estimate of the likelihood a particular patient has a given disease based on known factors

**Post-Test Probability**
- a revision of the probability of disease after a patient has been interviewed and examined
- calculation process can be more explicit using results from epidemiologic studies, knowledge of the accuracy of tests, and Bayes’ theorem
- the post-test probability from clinical examination is the basis of consideration when ordering diagnostic tests or imaging studies
- after each iteration the resultant post-test probability becomes the pre-test probability when considering new investigations

**Case-Control Study**
- odds ratio (OR) = \( \frac{A}{B} \div \frac{C}{D} = \frac{A \times D}{B \times C} \)

**Cohort Study**
- relative risk (RR) = \( \frac{A}{A+B} \div \frac{C}{C+D} = \frac{A}{A+B} \times \frac{C+D}{C+D} \)
- attributable risk = \( \frac{A}{A+B} - \frac{C}{C+D} \)

- (e.g. 24/30 = 80% sensitive)

**Figure 4d. Specificity of test**
- (e.g. 56/70 = 80% specific)

*Source: Loong TW. Understanding sensitivity and specificity with the right side of the brain. BMJ 2003;327:716-719*

**SPIN:** use a **S**pecific test to rule **IN** a hypothesis. Note that specific tests have very few false positives. If you get a positive test, it is likely a true positive

**SNOUT:** use a **SE**nsitive test to rule **OUT** a hypothesis. Note that sensitive tests have very few false negatives. If you get a negative test, it is likely a true negative

**Sensitivity and specificity**
- characteristics of the test
- LR depends on the test characteristics, not the prevalence
- PPV and NPV depend on the prevalence of the disease in the population
Figure 6. Clinical epidemiology definitions and practical example using FOBT testing in advanced colon cancer

<td>TP</td>
<td>FP</td>
</tr>
<tr>
<td>Negative</td>
<td>FN</td>
<td>TN</td>
</tr>
</tbody>
</table>

Sensitivity = TP/(TP+FN)  
Specificity = TN/(TN+FP)

Likelihood Ratio (LR)  
- Likelihood that a given test result would be expected in a patient with disease compared with the likelihood that the same result would be expected in a patient without disease  
- LR+ indicates how much the probability of disease increases if the test is positive  
- LR- indicates how much the probability of disease decreases if the test is negative

LR+ = \frac{Sensitivity}{1 - Specificity}  
LR- = \frac{1 - Sensitivity}{Specificity}

Positive Predictive Value (PPV)  
- Proportion of people with a positive test who have the disease

PPV = \frac{TP}{TP + FP}

Negative Predictive Value (NPV)  
- Proportion of people with a negative test who are free of disease

NPV = \frac{TN}{TN + FN}

Pre-Test Probability  
- An estimate of the likelihood a particular patient has a given disease based on known factors such as clinical assessment prevalence of disease in the population. Together with a post-test probability this can be used to interpret a diagnostic test or a series of tests

Pre-Test Odds = \frac{Pr \_prevalence}{1 - Pr \_prevalence}

Post-Test Probability  
- A revision of the probability of disease after a patient has been examined or a diagnostic test has been conducted  
- Calculation process can be more explicit using results from epidemiologic studies, knowledge of the accuracy of tests and Bayes’ theorem  
- The post-test probability from clinical examination is the basis of consideration when ordering diagnostic tests or imaging studies  
- After each iteration the resultant post-test probability becomes the pre-test probability when considering new investigations

Post-Test Odds = Pre-Test Odds \times LR  
Post-Test Probability = \frac{Post-Test odds}{Post-Test odds + 1}

Intention-To-Treat (ITT)  
- A strategy for analyzing data in which all participants are included in the group to which they were assigned, whether or not they completed the requirements of that group  
- This is to limit the bias introduced by issues of compliance and to simulate real world situations in which not all patients/providers adhere to the study allocation protocol

Relative Risk (RR)  
- Ratio of the incidence of a health outcome among the exposed population to the incidence of the health outcome in the non-exposed population

Relative Risk (RR) = \frac{\text{PPV}}{\text{NPV}} = \frac{[TP/(TP+FP)]}{[FN/(TN+FN)]}

Attributable Risk (AR)  
- Rate of a health outcome attributable to a hypothetical risk factor for that outcome  
- [incidence in exposed population] - [incidence in non-exposed]  
- Attributable risk assumes causation

Attributable Risk = \frac{\text{PPV} - (1 - \text{NPV})}{[TP/(TP+FP)] - [FN/(TN+FN)]}

Attributable Risk = \frac{PPV - (1 - NPV)}{[TP/(TP+FP)] - [FN/(TN+FN)]}

| LR+ | 0.239 | = 3.85 |
| LR- | 0.938 | = 0.81 |
| PPV | 68/(68+147) = 0.316 |
| NPV | 2234/(2234+216) = 0.912 |

Odds Ratio (OR)  
- Statistic based on the ratio of two odds, used for estimating the strength of association of a factor  
- Statistically significant OR above 1.0 indicates an elevated risk among those exposed beyond chance  
- Statistically significant OR lower than 1.0 indicates that the exposure may be protective beyond chance
Effectiveness of Interventions

DEFINITIONS

Relative Risk Reduction (RRR)
- proportional reduction in rates of adverse outcomes between experimental and control participants in a trial

Absolute Risk Reduction (ARR)
- absolute arithmetic difference in rates of adverse outcomes between experimental and control participants in a trial
- it is hypothesized that events will occur more often in control group than in experimental group where the intervention is protective (e.g. a vaccine)

Absolute Risk Increase (ARI)
- absolute arithmetic difference in rates of adverse outcomes between control and experimental participants in a trial
- it is hypothesized that events will occur more often in experimental group than in control group when the intervention is harmful (e.g. alcohol excess)

Number Needed to Treat (NNT)
- number of patients who need to be treated to achieve one additional favorable outcome
- only one of many factors that should be taken into account in clinical or health system decision making (e.g. must take into account cost, ease, feasibility of intervention)

Number Needed to Harm (NNH)
- number of patients who, if they received the experimental treatment, would lead to one additional patient being harmed, compared with patients who received the control treatment

Adherence (Formerly Compliance)
- degree to which a patient follows a treatment plan

Effectiveness, Efficacy, Efficiency
- three measurements indicating the relative value (beneficial effects vs. harmful effects) of an intervention
  - efficacy: the extent to which a specific intervention produces a beneficial result under ideal conditions
    - ideally, based on the results of a randomized control trial (the theoretical impact)
  - effectiveness: measures the benefit of an intervention under usual conditions of clinical care
    - considers both the efficacy of an intervention and its actual impact on the real world, taking into account access to the intervention, whether it is offered to those who can benefit from it, its proper administration, acceptance of intervention, and degree of adherence to intervention
  - efficiency: a measure of economy of an intervention with known effectiveness
    - considers the optimal use of resources (e.g. money, time, personnel, equipment, etc.)

Quantitative Research Methods

Observational Study Designs

- observational studies involve neither the manipulation of the exposure of interest nor randomization of the study subjects
- there are two main subtypes of observational studies: descriptive and analytic studies

Descriptive Studies
- describe the events and rates of disease with respect to person, place and time and to estimate disease frequency and time trends
- first sets of studies and are used to generate an etiologic hypothesis, not test a hypothesis

Analytic Studies
- observational studies used to test a specific hypothesis
- includes ecological studies, cohort studies, case-control studies, and cross-sectional studies

Table 5. Observational Study Designs

<th>Cohort (Figure 9)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Methods</td>
<td>Descriptions of the average exposure or risk of disease for a population</td>
<td>Collect information from each person at one particular time: tabulate the numbers in groups (e.g. by presence or absence of disease/factor of interest)</td>
<td>Ask cases and controls about exposures, select all the cases of a specific disease during a specific time frame: representative of spectrum of clinical disease; select controls (see PH7): represent the general population. To minimize risk of bias, may select more than one control group and/or match controls to cases (e.g. age, gender). Association can be concluded between the risk factor and the disease (odds ratio).</td>
<td>Subjects are followed for a specific period of time to determine development of disease in each exposure group. Prospective: measuring from the exposure to the future outcomes – looking forward. Retrospective: measuring from outcomes to possible risk factors or protective factors – looking back. Collect information on factors from all persons at the beginning of the study: tabulate the number of persons who develop the disease or other measured outcomes of morbidity. Provides estimates of incidence, relative risk, attributable risk.</td>
</tr>
<tr>
<td>Advantages</td>
<td>Quick, easy to do studies using readily available data, generates hypotheses</td>
<td>Determines association between variables: quick and uses limited resources. Surveys with validated questions allow comparison between studies.</td>
<td>Used when disease in population is rare (less than 10% of population) due to increased efficiency. Less costly and time consuming.</td>
<td>Shows an association between a factor and an outcome/several outcomes. Stronger evidence for causation.</td>
</tr>
<tr>
<td>Disadvantages</td>
<td>Poor generalizability to individual level (not direct assessment of causal relationship). Ecological fallacy: an incorrect inference about individuals in the population.</td>
<td>Does not allow for assessment of temporal relationship or causation between variables. Recall bias (see PH7).</td>
<td>Recall bias (see PH7). Confounding. Selection bias for controls: only one outcome can be measured.</td>
<td>By itself, cannot establish causation. Confounding factors are common as the cohort self-selects the exposure, or unknown/unmeasured factors are associated with the measured exposure. Cost and duration of time needed to follow cohort.</td>
</tr>
<tr>
<td>Examples</td>
<td>A study looking at the association between smoking rates and lung cancer rates in different countries at the population level without individual data on both factors.</td>
<td>A study that examines the distribution of BMI by age in New York at a particular point in time.</td>
<td>A famous case control study is by Sir Richard Doll who demonstrated the link between tobacco smoking exposure and lung cancer cases at the individual level.</td>
<td>A famous cohort study is the Framingham Heart Study, which assessed the long-term cardiovascular risks of diet, exercise, medications such as ASA, etc.</td>
</tr>
</tbody>
</table>

Experimental Study Designs

- not discussed here are non-randomized control trials (e.g. allocation by clinic or other non-random basis - performed when randomization is not possible) and clinical trials (test treatments or laboratory tests in human subjects)

RANDOMIZED CONTROLLED TRIAL (RCT)

Definition
- subjects are assigned by random allocation to two or more groups, one of which is the control group, the other group(s) receive(s) an experimental intervention

Subjects
- individuals are separated into groups by a random process to ensure as much as possible equal distribution of known and unknown factors except for the experimental exposure (e.g. the treatment)
Methods
• random allocation of individuals into two or more treatment groups through a centralized concealed process
• method of assessment to reduce bias
  ▪ single-blind: subject does not know group assignment (intervention or placebo)
  ▪ double-blind: subject and observer both unaware of group assignment
  ▪ triple-blind: subject, observer, and analyst unaware of group assignment (rarely done)
• one group receives placebo or standard therapy
• one or more groups receive(s) the intervention(s) under study
• the outcome is measured and the groups are compared
• all other conditions are kept the same between groups

Advantages
• “gold standard” of studies, upon which the practice of EBM is founded
• provides the strongest evidence for effectiveness of intervention
• with sufficient sample size and appropriate randomization, threats to validity are minimized
• allows prospective assessment of the effects of intervention while minimizing bias

Disadvantages
• some exposures are not amenable to randomization (e.g. cannot randomize subjects to poverty/wealth or to harmful exposures such as smoking) due to ethical or feasibility concerns
• difficult to randomly allocate groups (e.g. communities, neighbourhoods)
• difficult to study rare events, since RCTs would require extremely large sample sizes
• costly

Methods of Analysis

Distributions
• distribution describes the probability of events
• normal (Gaussian) or non-normal (skewed, bimodal, etc.)
• characteristics of the normal distribution
  ▪ mean = median = mode
  ▪ 67% of observations fall within one standard deviation of the mean
  ▪ 95% of observations fall within two standard deviations of the mean
• measures of central tendency
  ▪ mean: sum of all observations divided by total number of variables
  ▪ median: value at the 50th percentile, this is a better reflection of the central tendency for a skewed distribution
  ▪ mode: most frequently observed value in a series
• measures of dispersion
  ▪ range: the largest value minus the smallest value
  ▪ variance: a measure of the spread of data
  ▪ standard deviation: the average distance of data points from the mean (the positive square root of variance)
• given the mean and standard deviation of a normal or binomial distribution curve, a description of the entire distribution of data is obtained

Data Analysis

Statistical Hypotheses
• null (H₀)
  ▪ no relationship exists between the two stated variables (i.e. no association between the hypothesized exposure and the outcome)
• alternative (H₁)
  ▪ a relationship does exist between the two stated variables

Type I Error (α Error)
• the null hypothesis is falsely rejected (i.e. concluding an intervention X is effective when it is not, or declaring an observed difference to be real rather than by chance)
• the probability of this error is denoted by the p-value
• studies tend to be designed to minimize this type of error, since a type I error can have larger clinical significance than a type II error

Type II Error (β Error)
• the null hypothesis is falsely accepted (i.e. stating intervention X is not effective when it is, or declaring an observed difference/effect to have occurred by chance when it is present)
• higher level of error is acceptable for most studies
• can also be used to calculate statistical power

Power
• probability of correctly rejecting a null hypothesis when it is in fact false (i.e. the probability of finding a specified difference to be statistically significant at a given p-value)
• power increases with an increase in sample size
• power = 1 – β, and is therefore equal to the probability of a true positive result

Statistical Significance
• the probability that the statistical association found between the variables is due to random chance alone (i.e. that there is no association)
• the preset probability is set sufficiently low that one would act on the result; frequently p=0.05
• when statistical tests result in a probability less than the preset limit, the results are said to be statistically significant (i.e. p<0.05)

Clinical Significance
• measure of clinical usefulness (e.g. 1 mmHg BP reduction may be statistically significant, but may not be clinically significant)
• depends on factors such as cost, availability, patient compliance, and side effects in addition to statistical significance

Trend
• an observed directional relationship that does not meet criteria for statistical significance and thus should be interpreted with caution

Confidence Interval (CI)
• provides a range of values within which the true population result (e.g. the mean) lies
• frequently reported as 95% CI (i.e. one can be 95% certain that the true value is within this data range)
• bounded by the upper and lower confidence limits

Data
• information collected from a sample of a population
• there are 2 overall classes of data listed with examples
  • discrete
    • categorical (e.g. gender, marital status)
    • ordinal (e.g. low, medium, high)
  • continuous (e.g. serum cholesterol, hemoglobin, age)

Accuracy
• how closely a measurement approaches the true value

Reliability
• how consistent a measurement is when performed by different observers under the same conditions or by the same observer under different conditions

Validity
• extent to which a measurement approaches what it is designed to measure
• determined by the accuracy and reliability of a test

Internal Validity
• degree to which the findings of the sample truly represent the findings in the study population
• dependent on the precision and accuracy

External Validity
• degree to which the results of the study can be generalized to other situations or populations
Common Statistical Tests

Causation

Criteria for Causation (Sir Bradford Hill)

1. **strength of association**: the frequency with which the factor is found in the disease and the frequency with which it occurs in the absence of disease
2. **consistency**: is it the same outcome with different populations or study design?
3. **specificity**: is the association particular to your intervention and measured outcome?
4. **temporal relationship**: did the exposure occur before the onset of the disease?
5. **biological gradient**: finding a quantitative relationship between the factor and the frequency (e.g. dose response relationship)
6. **biological plausibility**: does the association/causation make biological sense?
7. **coherence**: can the relationship be explained/accounted for based on what we know about the laws of science, logic, etc.?
8. **experimental evidence**: experiment that investigates what happens when the suspected offending agent is removed (e.g. is there improvement?)
9. **analogy**: do other established associations provide a model for this type of the relationship?

Note: Not all criteria must be fulfilled to establish scientific causation, and the modern practice of EBM emphasises ‘experimental evidence’ as superior to other criteria for experimental causation review. However many causation questions in health cannot be answered with experimental methods.

- visit [http://phprimer.afmc.ca](http://phprimer.afmc.ca) and refer to Table 5.4: Criteria for inferring a causal relationship from the AFMC Primer on Population Health

Assessing Evidence

- critical appraisal is the process of systematically examining research evidence to assess validity, results, and relevance before using it to inform a decision
A. Are the results of the study valid?
   • see below for classifications of evidence that has already been assessed; see sidebar for assessing primary studies

B. What are the results?
   • what was the impact of the treatment effect?
   • how precise was the estimate of treatment effect?
   • what were the confidence intervals and power of the study?

C. Will the results help me in caring for my patients?
   • are the results clinically significant?
   • can I apply the results to my patient population?
   • were all clinically important outcomes considered?
   • are the likely treatment benefits worth the potential harm and costs?

Levels of Evidence: Classifications Cited in Guidelines/Consensus Statements

Level I evidence: based on RCTs (or meta-analysis of RCTs) big enough to have low risk of incorporating FP or FN results
Level II evidence: based on RCTs too small to provide Level I evidence; may show positive trends that are non-significant, or have a high risk of FN results
Level III evidence: based on non-randomized, controlled or cohort studies; case series; case-controlled; or cross-sectional studies
Level IV evidence: based on opinion of respected authorities or expert committees, as published consensus conferences/guidelines
Level V evidence: opinions of the individuals who have written/reviewed the guidelines (i.e. Level IV evidence), based on experience/knowledge of literature/peer discussion

Notes: These 5 levels of evidence are not direct evaluations of evidence quality or credibility; they reflect the nature of the evidence. While RCTs tend to be most credible (with <III), level III evidence gains credibility when multiple studies from different locations and/or time periods report consistent findings. Level IV and V evidence reflects decision-making that is necessary but in the absence of published evidence.

META-ANALYSIS

Definition
• a form of statistical analysis that combines the results of independent studies addressing a common research hypothesis, as identified through systematic review, into one large study

Subjects
• combination of all the subjects used in original studies

Methods
• selection of relevant studies from the published literature which meet quality criteria
• statistical models used to combine the results of each independent study
• provides a summary statistic of overall results as well as graphic representation of included studies
Advantages
- attempts to overcome the problem of reduced power due to small sample sizes of individual studies
- ability to control for inter-study variation

Disadvantages
- sources of bias may not be controlled for
- reliance on published studies may increase the potential conclusion of an effect as it can be difficult to publish studies that show no significant results (publication bias)
- the decision to include/reject a particular study is subjective

Health Services Research

Continuous Quality Improvement

Quality Improvement
- method of evaluating and improving processes; focusing more on systems and systematic biases, which are thought to be the cause of variation in quality, as opposed to individuals
- taking measures to increase efficiency of action with the purpose of achieving optimal quality

Quality Assurance
- management system to assure the quality of health care provided by workers and received by patients
- constantly aims to improve standards and the frequency of attaining those standards
- five-stage process of quality assurance
  1. establishment of functional goals
  2. implementation of procedures to achieve those goals
  3. regular assessment of performance relative to the goals
  4. proposal of solutions to close the gap between performance and goals
  5. documentation and reporting of this assessment activity

Quality Control
- method of maintaining standards by reviewing the quality of all factors involved in the process

Continuous Quality Improvement
- management approach to improve and maintain quality via continuous assessment of potential defects, followed by action to improve process, avoid decrease in quality or correcting process in early stages
- continuous feed-forward process

Quality Management
- encompasses quality assurance, quality control, and quality improvement to achieve consistent quality

Total Quality Management
- management philosophy for improving quality while controlling costs
- focusing on the system rather than the individual, to ensure decisions are made to support quality and remove barriers to quality inherent in bureaucratic, hierarchical systems

Audit
- process of systematic examination of a quality system carried out by internal or external quality auditors
- to determine whether quality processes and results comply with goals, and whether processes have been implemented effectively

Systems Analyses Tools
1. 5 Whys: brainstorming to simplify the process of change; continue asking ‘why’ until the root of the problem is discovered
2. Ishikawa Diagrams (i.e. Fishbone Diagrams): identify generic categories of problems that have an overall contribution on the effect
3. **Defect check sheets**: consider all defects and tally up the number of times the defect occurs
4. **Pareto Chart**: x vs. y chart; x-axis = defect categories, y-axis = frequency; plot cumulative frequency on the right y-axis
   - purpose is to highlight most important among large set of factors contributing to defects/poor quality

**Precede-Proceed Model**
- tool for designing, implementing, and evaluating health interventions/programs

**Table 7. Precede-Proceed Model**

<table>
<thead>
<tr>
<th>PRECEDE Phase</th>
<th>PROCEED Phase</th>
</tr>
</thead>
<tbody>
<tr>
<td>Phase 1 – Identify the ultimate desired result</td>
<td>Phase 5 – Implementation (design and conduct the intervention)</td>
</tr>
<tr>
<td>Phase 2 – Identify and set priorities among health issues and their behavioural and environmental determinants</td>
<td>Phase 6 – Process Evaluation (determine if the program is implemented as planned)</td>
</tr>
<tr>
<td>Phase 3 – Identify the predisposing, enabling, and reinforcing factors that affect the behaviors and environmental determinants</td>
<td>Phase 7 – Impact Evaluation (measure intermediate objectives – predisposing, enabling, and reinforcing factors)</td>
</tr>
<tr>
<td>Phase 4 – Identify the administrative and policy factors that influence what can be implemented</td>
<td>Phase 8 – Outcome Evaluation (measure desired result)</td>
</tr>
</tbody>
</table>

**Cost Analysis**

**Cost-Benefit Analysis (CBA)**
- a process of, either explicitly or implicitly, weighing the total expected costs against the total expected benefits of one or more actions in order to choose the best or most profitable option
- all costs are adjusted for the time value of money so that costs that may change over time are expressed on a common basis in terms of their present value

**Cost Effectiveness Analysis (CEA)**
- a comparison of the relative expenditure (costs) and outcomes (effects) of two or more courses of action
- cost effectiveness analysis is often used where a full cost benefit analysis is inappropriate
- a CEA is commonly expressed in terms of a ratio: the denominator is a gain in health from a measure (e.g. years of life, premature births averted, sight-years gained) and the numerator is the cost of the health gain
- the most commonly used outcome measure is quality-adjusted life years (QALY), see PH7

**Outbreak of Infectious Diseases**

**Definitions**

**Outbreak**
- occurrence of new cases clearly in excess of the baseline frequency of the disease in a defined community or population over a given period of time
- synonymous with epidemic, although generally considered to be an epidemic that is localized, has an acute onset, or is relatively short in duration
Epidemic
- any disease, infectious or chronic, occurring at a greater frequency than usually expected in a defined community or institutional population over a given time period (i.e. excessive rate of disease)

Endemic
- constant presence of disease or infectious agent in a given geographic area or population subgroup (i.e. usual rate of disease)

Pandemic
- epidemic over a wide area, crossing international boundaries, and affecting a large number of people

Attack Rate
- cumulative incidence of infection within a defined group observed during a specific period of time in an epidemic
- calculated by dividing the total number of people who develop clinical disease by the population at risk, usually expressed as a percentage

Secondary Attack Rate
- number of cases among contacts occurring within the incubation period following exposure to the primary case, in relation to the total exposed contacts
- infectiousness reflects the ease of disease transmission and is usually measured by the secondary attack rate

Pathogenicity Rate
- power of an organism to produce clinical disease in those that are affected

Virulence
- severity of the disease produced by the organism in a given host
- expressed as the ratio of the number of cases of severe and fatal infection to the total number of clinically affected

Case-Fatality Rate
- proportion of individuals contracting a disease who die as a result of that disease
- most frequently applied to a specific outbreak of acute disease in which all patients have been followed for an adequate period of time to include all attributable deaths
- must be clearly differentiated from the mortality rate

Mortality Rate/Crude Death Rate
- estimation of the portion of the population that dies during a specified period from all causes of death

All-Cause Mortality Rate by Age Group
- estimation of the portion of the population in a given age group that dies during a specified period from all causes of death for that age group

Morbidity Rate
- estimation of the portion of the population that suffers illness or ill health during a specified period

**Steps to Control an Outbreak**

1. **Define the Problem**
   - is it an outbreak?

2. **Appraise Existing Data and Institute a Surveillance System**
   - **case definition**: formulated from the most common symptoms or signs; definition includes the likely date of onset of illness of the first case (e.g. any person with onset of fever higher than 101.3°F and cough within past 28 d)
   - **active surveillance**: identify those who may have been exposed to the infectious agent and who fit the case definition through active efforts, including:
     - contacting emergency rooms, physicians’ offices, local schools
     - obtaining records from health units, such as mortality or laboratory records

3. **Formulate Hypotheses and Implement Initial Control Measures**
   - track outbreak evolution to develop hypotheses about potential source and populations at risk
   - case management depends on symptoms, suspected agent, population at risk, and location

**Infection Control Precautions**
(see Infectious Diseases, ID6)

- **Contact** (impetigo, chicken pox, warts)
  - Wash hands
  - Gloves
  - Gown
  - Wipe equipment after use

- **Airborne** (TB)
  - Contact precautions PLUS
  - N95 mask (fit tested)
  - Negative pressure room

- **Droplet** (influenza, mumps, pneumonia)
  - Contact precautions PLUS
  - Goggles/face shield
  - Surgical mask

**Active Surveillance**
Outreach such as visits or phone calls by the public health/surveillance authority to detect unreported cases (e.g. an infection control nurse goes to the ward and reviews temperature charts to see if any patient has a nosocomial infection)

**Passive Surveillance**
A surveillance system where the public health/surveillance authority depends on others to submit standardized forms or other means of reporting cases (e.g. ward staff notify infection control when new cases of nosocomial infections are discovered)
• population management requires public health services in the community and infection control
teams in hospitals to disseminate information about
  ▪ risk reduction
  ▪ personal preventative measures (e.g. post-exposure prophylaxis)
  ▪ decreasing risk of propagation (e.g. quarantine)

4. Test the Hypothesis through Analysis of Surveillance Data or Special Studies
• analyze outbreak surveillance data
• generate epidemic curves
  ▪ usually a frequency histogram, with the number of cases plotted on the vertical axis and
dates or times of onset along the horizontal axis
  ▪ curve can indicate whether the epidemic (outbreak) has a common source or whether it is propagated
  ▪ point source epidemic: exposure is brief and essentially simultaneous
  ▪ extended source epidemic: exposure lasts for a period of days to weeks and may be
  continuous (no irregular peaks) or intermittent (irregularly spaced peaks)
  ▪ propagated epidemic: begins with only a few exposed persons but is maintained by person-to-person transmission (e.g. measles/influenza); epidemic curve shows a series of peaks
• use epidemic curves, cross-sectional studies, and/or case-control studies to evaluate hypotheses
  about cause of outbreak

5. Draw Conclusions and Re-Adjust Hypothesis and Control Measures
• establish cause of outbreak with further epidemiologic investigation and revise initial control
  measures accordingly

6. Plan for Long-Term Prevention and Control
• implement prevention measures to avoid similar future incidents
  ▪ strengthen resistance of hosts (e.g. immunization)
  ▪ interrupt modes of transmission in environment (e.g. improvements in food processing)
• communicate outbreak prevention and control strategies to the public

Environmental Health

Definition
• study of conditions in the natural and human-made environment that influence human health
  and well-being
• environmental exposures
  ▪ four main reservoirs: air, food, water, and soil
  ▪ three main routes: inhalation, ingestion, or absorption (skin)
  ▪ usually divided into two main settings
    ▪ workplace (including schools): may see high level exposure in healthy individuals (see
  Occupational Health, PH23)
    ▪ non-workplace: generally low level but chronic exposure; population at risk includes
  extremes of age, developing fetuses, and ill or immunocompromised individuals
• health impacts of the environment also include factors such as urban planning and how
  individuals interact with the built environment (e.g. safe pedestrian and bicycle paths are
  neighborhood features that can facilitate more active lifestyles among residents)

Environmental Health Jurisdiction

Risk Assessment

Hazard Identification
- what is the hazard involved?
- assess potential hazards by taking an environmental health history

Risk Characterization
- is the identified agent likely to elicit the patient's current symptoms?
- review known health impacts of the hazard and identify specific properties that contribute to or diminish adverse effects (e.g. evaluate threshold levels)

Exposure Assessment
- is the patient's exposure to the environmental agent sufficient to have caused the current symptoms?
- quantify exposure through direct measurement or by reviewing frequency and nature of contact with hazard

Air

Physical Contaminants
- sound waves
  - ionizing radiation
  - radon is naturally produced by soil containing uranium or radium, can contaminate indoor air and is associated with a small proportion of lung cancers
- ultraviolet radiation is increasing due to ozone layer destruction and increases risk of skin cancer
  - non-ionizing radiation
  - visible light, infrared, microwave

Chemical Contaminants
- ground-level ozone
  - main component of smog with levels increasing in major cities
  - worsens asthma, irritates upper airway
- carbon monoxide (fossil fuel-related, common byproduct of combustion)
  - aggravates cardiac disease at low levels
  - headache, nausea, dizziness at moderate levels
  - fatal at high levels
- sulphur dioxide (fossil fuel-related), nitrogen oxides
  - contribute to acid rain and exacerbate breathing difficulties
- organic compounds at high levels (e.g. benzene, methylene chloride, tetrachloroethylene)
  - tend to be fat-soluble, easily absorbed through skin and difficult to excrete
- heavy metals emissions (e.g. nickel, cadmium, chromium)
  - variety of health effects: upper airway disease, asthma, decreased lung function
  - second-hand tobacco smoke
  - respiratory problems, increase risk of lung cancer
  - particulates associated with decreased lung function, asthma, upper airway irritation

Biological Contaminants
- molds thrive in moist areas; 10-15% of the population allergic
- bacteria survive as spores and aerosols, can be distributed through ventilation systems (e.g. Legionella)
- dust mites (year-round) and pollens (seasonal) can trigger upper and lower-airway symptoms

Climate Change
- anthropogenic greenhouse gas emissions (e.g. carbon dioxide, methane) leading to adverse changes in the global environment
- increased extreme weather conditions (e.g. floods, hurricanes, heat waves)
- increased distribution of disease vectors (e.g. mosquitoes and malaria)

BPA, the Toxin Concern of 2009
Bisphenol A (BPA) is a chemical compound found in some hard, clear, lightweight plastics and resins. According to the NIH, animal studies suggest that ingested BPA may imitate estrogen and other hormones. In October 2008, Canada became the first country in the world to ban the import and sale of polycarbonate baby bottles containing BPA, stating that although exposure levels are below levels that cause negative effects, current safety margins need to be higher. The US FDA does not consider normal exposure to BPA to be a hazard, however the NIH has some concern that fetuses, infants, and children exposed to BPA may be at increased risk for early-onset puberty, prostate, and breast cancer.
Water

Biological Contaminants
- mostly due to human and animal waste
- rural inhabitants at higher risk
- bacteria: Escherichia coli (e.g., Walkerton, ON), Salmonella, Pseudomonas, Shigella
- protozoa: Giardia, Cryptosporidium (e.g., North Battleford, SK)

Chemical/Industrial Contaminants
- chlorination by-products (e.g., chloroform can cause cancer at high levels)
- volatile organic compounds, heavy metals, pesticides, and other industrial waste products can be present in groundwater
- fluoride at high levels (greater than that of municipal fluoridation) can cause skeletal fluorosis

Soil

- contamination sources: rupture of underground storage tanks, use of pesticides and herbicides, percolation of contaminated water runoffs, leaching of wastes from landfills, dust from smelting and coal burning power plants, residue of industrial waste development (e.g., urban agriculture), lead deposition, leakage of transformers
- most common chemicals: petroleum hydrocarbons, solvents, lead, pesticides, motor oil, other industrial waste products
- health effects
  - infants and toddlers at highest risk of exposure due to hand-mouth behaviors
  - dependent on contaminant: leukemia, kidney damage, liver toxicity, neuromuscular blockade, developmental damage to the brain and nervous system, skin rash, eye irritation, headache, N/V, fatigue
- biological contamination: tetanus, Pseudomonas

</tbody>
</table>

Food

- other biological food contaminants include
  - viruses, mold toxins (e.g., aflatoxin has been associated with liver cancer), parasites (e.g., Toxoplasmosis, tapeworm), paralytic and shellfish poisoning (rare), genetically modified organisms (controversial as to health risks/benefits)

Chemical Contaminants
- many persistent organic pollutants are fat-soluble and undergo bioamplification
- drugs (antibiotics, hormones)
- inadequately prepared herbal medications
- food additives and preservatives
  - nitrates highest in cured meats; can be converted to carcinogenic nitrosamines
  - sulphites commonly used as preservatives; associated with sulphite allergy (hives, nausea, shock)
- pesticide residues
  - older pesticides (e.g., DDT) have considerable human health effects
  - polychlorinated biphenyls (PCBs)
  - effects (severe acne, numbness, muscle spasm, bronchitis) much more likely to be seen in occupationally exposed individuals than in the general population
- dioxins and furans
  - levels highest in fish and marine mammals, also present in breast milk
  - can cause immunosuppression, liver disease, respiratory disease

To Fluoridate or Not
At the recommended concentration of 0.8-1.0 mg/L, fluoride reduces cavities by 18-40%, and there is little risk of fluorosis unless other exposures (e.g., toothpaste, rinses, mouthwash, etc.) are swallowed. Opposition raises concerns that the intake is not easily controlled, and that children, and others may be more susceptible to health problems. However, public health experts strongly support fluoridation as an effective measure to prevent dental caries at the community level and reduce dental health inequities

The Walkerton Tragedy
In May 2000, the drinking water system in the town of Walkerton, ON, became contaminated with Escherichia coli 0157:H7 and Campylobacter jejuni. Over 2,300 individuals became ill; 27 people developed hemolytic uremic syndrome and 7 individuals died in the outbreak

Honey and Botulism
Although exceedingly rare, infant botulism has been documented as a form of food poisoning from C. botulinum found in honey. When an infant swallows spores of this bacterium, they grow and produce a toxin in the baby’s intestine. By the time an infant is 1, its gut has a healthy population of beneficial bacteria which prevent this from occurring

Organic Foods
- Organic foods are not free of synthetic pesticide residues but typically contain smaller amounts compared to conventionally grown foods
- Currently, there has not been strong evidence to suggest that eating organic foods is safer or more nutritious compared to eating conventionally grown food

Heavy Metal Toxicity

Mechanism
• after exposure, superabundant metals bind to proteins, alter their enzymatic activity, and lead to diffuse disease manifestations

Predisposing Factors in At-Risk Groups
• children: hand-to-mouth, incomplete blood-brain barrier
• pregnant women and developing fetus: heavy metals cross placenta; mothers release heavy metal stores at times of calcium stress
• adults: occupation, hobbies, environment (home, country)

Etiology
• iatrogenic (e.g. gold treatment for rheumatoid arthritis, lithium treatment for bipolar affective disorder)
• inhalation (e.g. zinc oxide, lead, gasoline fumes)
• ingestion (e.g. lead paint, mercury in fish, folk remedies)
• industry (e.g. methyl mercury industrial spill caused Minamata disease)

Treatment
• generalized workup: symptoms are usually wide-ranging and non-specific
• chelation therapy (e.g. dimercaprol)

Occupational Health

• occupational health is the maintenance and promotion of health in the work environment
• services encompass health promotion and protection (primary prevention), disease prevention (secondary prevention), and treatment and rehabilitation (tertiary prevention)
• general bias towards reporting occupational injuries vs. occupational disease, as occupational disease is harder to identify

Workplace Health Promotion and Protection

• take action in the workplace so the worker is protected from injury or illness
  • identifying workplace hazards (e.g. through material safety data sheets [MSDS])
  • assessing risk
  • reducing exposure
    • source: substituting a less toxic chemical
    • path: enclosing a source of noise in a sound-proof room
    • worker: personal protection equipment (e.g. reflective vests, helmets)
    • worker education: emergency protocols, material safety education
    • rotation of workers: decrease exposure for each worker but more workers exposed

Workplace Disease Prevention

• monitor workers’ health to prevent the development of disease
  • periodic examinations to facilitate pre-symptomatic diagnosis (e.g. screening for lead exposure); substance misuse screening where performance impairment is suspected

Workplace Treatment and Rehabilitation

• treat injury or illness with safe return to the workplace
• may require rehabilitation, retraining, change in job duties, and/or workers’ compensation

Workplace Legislation

• Department of Labor (DOL) administers and enforces more than 180 federal laws that cover many workplace activities for about 10 million employers and 125 million workers
• the Occupational Safety and Health (OSH) Act is administered by the Occupational Safety and Health Administration (OSHA)
• safety and health conditions in most private and public industries are regulated by OSHA or OSHA-approved state programs
employers must comply with the General Duty Clause of the OSH Act, which requires employers to keep their workplace free of serious recognized hazards
compliance duties owed to each employee include the provision of personal protective equipment and training as necessary
employees retain the right to
- ask OSHA to inspect their workplace
- use their rights under the law without retaliation and discrimination
- receive information and training about hazards, methods to prevent harm, and the OSHA standards that apply to their workplace. The training must be in a language you can understand
- get copies of test results done to find hazards in the workplace
- review records of work-related injuries and illnesses
- get copies of their medical records
OSHA enforces the Act through workplace inspections and investigations

Taking an Occupational Health History

- current and previous job duties
- exposures
  - identification: screen for chemical, metal, dust, biological, and physical hazards as well as psychological stressors; review relevant workplace MSDS
  - assessment: duration, concentration, route, exposure controls (e.g. ventilation, personal protective equipment)
- temporal relationship: changes in symptoms in relationship to work environment
- presence of similar symptoms in co-workers
- non-work exposures: home, neighborhood, hobbies

Occupational Hazards

<table>
<thead>
<tr>
<th>Physical</th>
<th>Chemical</th>

</table>
| Trauma (fractures, lacerations) | Organic solvents (e.g. benzene, methyl alcohol, most toxic is carbon tetrachloride) | Exposure to bacteria, viruses, fungi, protozoa, Rickettsia | Workload, responsibility, fear of job loss, geographical isolation, shift work, harassment (sexual/non-sexual)
| Noise (hearing loss)            | Mineral dusts (e.g. silica leads to silicosis and predisposition to TB, asbestos leads to diffuse fibrosis and mesothelioma, coal leads to pneumoconiosis) | Blood should be considered a potentially toxic substance due to blood-borne infectious diseases (e.g. HIV, hepatitis B) | Incurs high cost from absenteeism, poor productivity, mental illness (e.g. post-traumatic stress disorder) |
| Temperature (heat cramps, heat exhaustion, heat stroke) | Heavy metals (e.g. nickel, cadmium, mercury, lead) | Lead is ubiquitous and can cause severe disability | Dr. Howard Bigler |
| Air pressure (barotrauma, decompression sickness) | Lead is ubiquitous and can cause severe disability | Blood should be considered a potentially toxic substance due to blood-borne infectious diseases (e.g. HIV, hepatitis B) | Dr. Howard Bigler |
| Ergonomic                     | Gases (e.g. halogen gases, sulphur dioxide, carbon monoxide, nitrogen oxides) | Second-hand smoke (causal factor for lung cancer; lung disease, heart disease, asthma exacerbations; may be linked to miscarriage) | Dr. Howard Bigler |
| Repetitive use/overuse injuries, excessive force, awkward postures, poorly designed physical work environment | Second-hand smoke (causal factor for lung cancer; lung disease, heart disease, asthma exacerbations; may be linked to miscarriage) | Exposure restricted in most municipal, provincial, and federal jurisdictions | Dr. Howard Bigler |
| Tendosynovitis, bursitis, carpal tunnel syndrome | Radiation | Exposure restricted in most municipal, provincial, and federal jurisdictions | Dr. Howard Bigler |
| Radiation                      | Non-ionizing: visible light, infrared | Exposure restricted in most municipal, provincial, and federal jurisdictions | Dr. Howard Bigler |
| Ionizing: UV, x-rays, γ rays | Ionizing: UV, x-rays, γ rays | Exposure restricted in most municipal, provincial, and federal jurisdictions | Dr. Howard Bigler |
| Electricity                    | Electricity | Skin diseases (major portion of compensations, e.g. contact dermatitis, occupational acne, pigmentation disorders) | Dr. Howard Bigler |

Table 10. Occupational Hazards

Taking an Occupational Health History

WHACS
What do you do?
How do you do it?
Are you concerned about any particular exposures on or off the job?
Co-workers or others with similar problems?
Satisfied with your job?
As an essential part of the health system, physicians are required by law to report certain diseases to public health for the following reasons:

1. to control the outbreak
   - if the disease presents an outbreak threat (e.g. measles, *Salmonella*, respiratory diseases in institutions)
2. to prevent spread
   - if the disease presents a significant threat to individuals or a subset of the population (e.g. Lassa Fever)
3. for surveillance
   - if the disease is preventable with immunization (e.g. polio, diphtheria, congenital rubella)
4. if infected individuals require education, treatment and/or partner notification (e.g. gonorrhea, TB)
5. reporting details (website, office, etc.)
   - some are more urgent than others (must contact MOH)
   - physicians should also report unlisted diseases that appear in clusters

The following list is based on the reportable diseases in the province of Ontario, Canada for 2014
(Each state will have its own similar legislation)

Source: Health Protection and Promotion Act, O. Reg. 559/91, amended to O. Reg.49/07.

| Acquired Immunodeficiency Syndrome (AIDS) | Haemophilus influenzae b disease, invasive |
| Acute flaccid paralysis <15 yr | Hantavirus pulmonary syndrome |
| Amoebiasis | Hemorrhagic fevers, including: |
| Anthrax | i. Ebola virus disease |
| Botulism | ii. Marburg virus disease |
| Brucellosis | iii. Other viral causes |
| *Campylobacter* enteritis | i. Hepatitis A |
| Chancroid | ii. Hepatitis B |
| *Chlamydia trachomatis* infections | iii. Hepatitis C |
| Cholera | iv. Hepatitis D (Delta hepatitis) |
| *Clostridium difficile* associated disease (CDAD) outbreaks in public hospitals | Herpes, neonatal |
| Cryptosporidiosis | Human Immunodeficiency Virus (HIV) |
| Cyclosporiasis | Influenza |
| Cytomegalovirus infection, congenital | Lassa Fever |
| Diphtheria | Legionellosis |
| Encephalitis, including: | Leprosy |
| i. Primary, viral | Listeriosis |
| ii. Post-infectious | Lyme Disease |
| iii. Vaccine-related | Malaria |
| iv. Subacute sclerosing panencephalitis | Measles |
| v. Unspecified | Meningitis, acute: |
| Food poisoning, all causes | i. Bacterial |
| *Gastroenteritis, institutional outbreaks* | ii. Viral |
| Giardiasis, except asymptomatic cases | iii. Other |
| Gonorrhea | Meningococcal disease, invasive |
| Haemophilus influenzae b disease, invasive | Mumps |
| Respiratory infection outbreaks in institutions |
| Rubella |
| Rubella, congenital syndrome |
| Salmonellosis |
| Severe Acute Respiratory Syndrome (SARS) |
| Shigellosis |
| Smallpox |
| Streptococcal infections, Group A |
| invades |
| Streptococcal infections, Group B |
| neonatal |
| Syphilis |
| Tetanus |
| Transmissible spongiform encephalopathy, including: |
| i. Creutzfeldt-Jakob disease, all types |
| ii. Gerstmann-Sträussler-Scheinker syndrome |
| iii. Fatal familial insomnia |
| iv. Kuru |
| Trichinosis |
| Tuberculosis, active and latent |
| Tularemia |
| Typhoid Fever |
| Verotoxin-producing *E. coli* infection indicator conditions, including |
| Hemolytic Uremic Syndrome (HUS) |
| West Nile Virus illness, including: |
| i. West Nile fever |
| ii. West Nile neurological manifestations |
| Yellow Fever |
| Yersiniosis |

NOS not otherwise specified
OCD obsessive-compulsive disorder
ODD oppositional defiant disorder
PD personality disorder
PDD pervasive developmental disorder
PTSD post-traumatic stress disorder
rTMS repetitive transcranial magnetic stimulation
SNRI serotonin and norepinephrine reuptake inhibitors
SSRI selective serotonin reuptake inhibitor
TCA tricyclic antidepressant

Suicide

Epidemiology
• attempted:completed = 20:1
• M:F = 1:4 for attempts, 3:1 for completed

Risk Factors
• epidemiologic factors
  ▪ age: increases after age 14, second most common cause of death for ages 15-24, highest rates in persons >65 yr
  ▪ sex: male
  ▪ marital status: widowed/divorced
  ▪ living situation: alone; no children <18 yr old in the household
  ▪ other: stressful life events, access to firearms
• psychiatric disorders
  ▪ mood disorders (15% lifetime risk in depression; higher in bipolar)
  ▪ anxiety disorders (especially panic disorder)
  ▪ schizophrenia (10-15% risk)
  ▪ substance abuse (especially alcohol – 15% lifetime risk)
  ▪ eating disorders (5% lifetime risk)
  ▪ adjustment disorder
  ▪ conduct disorder
  ▪ personality disorders (borderline, antisocial)
• past history
  ▪ prior suicide attempt
  ▪ family history of suicide attempt/completion

Clinical Presentation
• symptoms associated with suicide
  ▪ hopelessness
  ▪ anhedonia
  ▪ insomnia
  ▪ severe anxiety
  ▪ impaired concentration
  ▪ psychomotor agitation
  ▪ panic attacks

Approach
Every Patient: “Have you had any thoughts of wanting to hurt or kill yourself?”
  ▪ passive ideation: would rather not be alive but has no active plan for suicide
    ▪ e.g. “I’d rather not wake up” or “I would not mind if a car hit me”
  ▪ active ideation
    ▪ e.g. “I think about killing myself”
  ▪ plan: “Do you have a plan as to how you would end your life?”
  ▪ intent: “You talk about wanting to die, but are you planning to do this?” or “What has stopped you from ending your life?”
  ▪ past attempts: highest risk if previous attempt in past year
    ▪ ask about lethality, outcome, medical intervention

Assessment of Suicidal Ideation
• onset and frequency of thoughts: “When did this start?” or “How often do you have these thoughts?”
• control over suicidal ideation: “Can you stop the thoughts or call someone for help?”
• lethality: “Do you want to end your life?” or “What do you think would happen if you actually took those pills?”
• access to means: “How will you get a gun?” or “Which bridge do you think you would go to?”
• past attempts: highest risk if previous attempt in past year
  ▪ ask about lethality, outcome, medical intervention
• time and place: “Have you picked a date and place? Is it in an isolated location?”
• provocative factors: “What makes you feel worse (e.g. being alone)?”
• protective factors: “What keeps you alive (e.g. friends, family, pets, faith, therapist)?”
• final arrangements: “Have you written a suicide note? Made a will? Given away your belongings?”
• practiced suicide or aborted attempts: “Have you ever put the gun to your head?” “Held the medications in your hand?” “Stood at the bridge?”
• ambivalence: “There must be a part of you that wants to live, after all you came here for help”

Assessment of Suicide Attempt
• setting (isolated vs. others present/chance of discovery)
• planned vs. impulsive attempt, triggers/stressors
• substance use/intoxication
• medical attention (brought in by another person vs. brought in by self to ED)
• time lag from suicide attempt to ED arrival
• expectation of lethality, dying
• reaction to survival (guilt/remorse vs. disappointment/self-blame)

Management
• proper documentation of the clinical encounter and rationale for management is essential
• higher risk (hospitalization needs to be strongly considered)
  ▪ patients with a plan, access to lethal means, recent social stressors, and symptoms suggestive of a psychiatric disorder
  ▪ do not leave patient alone; remove potentially dangerous objects from room
  ▪ if patient refuses to be hospitalized, consider involuntary admission as per state specific statutes
• lower risk
  ▪ patients who are not actively suicidal, with no plan or access to lethal means
  ▪ discuss protective factors and supports in their life, remind them of what they live for, promote survival skills that helped them through previous suicide attempts
  ▪ make a safety plan and an agreement that they will
    • not harm themselves
    • avoid alcohol, drugs, and situations that may trigger suicidal thoughts
    • follow-up with you at a designated time
    • contact a health care worker, call a crisis line, or go to an emergency department if they feel unsafe or if their suicidal feelings return or intensify
• depression: consider hospitalization if symptoms severe or if psychotic features are present; otherwise outpatient treatment with good supports and SSRIs/SNRIs
• alcohol-related: usually resolves with abstinence for a few days; if not, suspect depression
• personality disorders: crisis intervention/confrontation, may or may not hospitalize
• schizophrenia/psychosis: hospitalization might be necessary
• parasuicide/self-mutilation: long-term psychotherapy with brief crisis intervention when necessary

Psychotic Disorders

Definition
• characterized by a significant impairment in reality testing
  ▪ delusions or hallucinations (with/without insight into their pathological nature)
  ▪ behaving in a disorganized way so that it is reasonable to infer that reality testing is disturbed

Table 1. Differentiating Psychotic Disorders

</tbody>
</table>

Duration of Time Differentiates the following 3 Psychotic Disorders

- Brief Psychotic Disorder: <1 month
- Schizophreniform Disorder: 1-6 months
- Schizophrenia: >6 months

Delusions: fixed, false beliefs
Hallucinations: perceptual experiences without an external stimulus

Figure 1. Differentiating psychotic disorders with duration
Differential Diagnosis of Psychosis

- primary psychotic disorders: schizophrenia, schizophreniform, brief psychotic, schizoaffective, delusional disorder
- mood disorders: depression with psychotic features, bipolar disorder (manic or depressive episode with psychotic features)
- personality disorders: schizotypal, schizoid, borderline, paranoid, obsessive-compulsive
- general medical conditions: tumor, head trauma, dementia, delirium, metabolic, infection, stroke, temporal lobe epilepsy
- substance-induced psychosis: intoxication or withdrawal, prescribed medications, toxins

Schizophrenia

DSM-5 Diagnostic Criteria for Schizophrenia

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. two (or more) of the following, each present for a significant portion of time during a 1 mo period (or less if successfully treated). At least one of these must be (1), (2), or (3)

1. delusions
2. hallucinations
3. disorganized speech (e.g. frequent derailment or incoherence)
4. grossly disorganized or catatonic behavior
5. negative symptoms (i.e. diminished emotional expression or avolition)

B. for a significant portion of time since the onset of the disturbance, level of functioning in one or more major areas (e.g. work, interpersonal relations, self-care) is markedly below the level achieved prior to the onset (or when the onset is in childhood or adolescence, there is failure to achieve expected level of interpersonal, academic, or occupational functioning)

C. continuous signs of the disturbance persist for at least 6 mo. This 6 mo period must include at least 1 mo of symptoms (or less if successfully treated) that meet Criterion A (i.e. active-phase symptoms) and may include periods of prodromal or residual symptoms. During these prodromal or residual periods, the signs of the disturbance may be manifested by only negative symptoms or by two or more symptoms listed in Criterion A present in an attenuated form (e.g. odd beliefs, unusual perceptual experiences)

D. schizoaffective disorder and depressive or bipolar disorder with psychotic features have been ruled out because the patient either 1) no major depressive or manic episodes have occurred concurrently with the active-phase symptoms, or 2) if mood episodes have occurred during active-phase symptoms, they have been present for a minority of the total duration of the active and residual periods

E. the disturbance is not attributable to the physiological effects of a substance (e.g. drug of abuse, a medication) or another medical condition

F. if there is a history of autism spectrum disorder or a communication disorder of childhood onset, the additional diagnosis of schizophrenia is made only if prominent delusions or hallucinations, in addition to the other required symptoms of schizophrenia are also present for at least 1 mo (or less if successfully treated)

• specifiers: type of episode (e.g. first episode, multiple episodes, continuous), with catatonia, current severity based on quantitative assessment of primary symptoms of psychosis

Epidemiology

- prevalence: 0.3-0.7%, M:F = 1:1
- mean age of onset: females late-20s; males early- to mid-20s
- suicide risk: 5-6% die by suicide, 20% attempt suicide

Etiology

• multifactorial: disorder is a result of interaction between both biological and environmental factors
  - genetic: 40% concordance in monozygotic (MZ) twins; 46% if both parents have schizophrenia; 10% of dizygotic (DZ) twins, siblings, children affected
  - neurochemistry (dopamine hypothesis): excess activity in the mesolimbic dopamine pathway may mediate the positive symptoms of psychosis while decreased dopamine in the prefrontal cortex may mediate negative and cognitive symptoms. GABA, glutamate, and ACh dysfunction are also thought to be involved
  - neuroanatomy: decreased frontal lobe function; asymmetric temporal/limbic function; decreased basal ganglia function; subtle changes in thalamus, cortex, corpus callosum, and ventriciles; cytoarchitectural abnormalities
  - neuroendocrinology: abnormal growth hormone, prolactin, cortisol, and ACTH

Management of Acute Psychosis and Mania

• Ensure safety of self, patient, and other patients
• Have an exit strategy
• Decrease stimulation
• Assume a non-threatening stance
• IM medications (benzodiazepine + antipsychotic) often needed as patient may refuse oral medication
• Physical restraints may be necessary
• Do not use antidepressants or stimulants

Relationship Between Duration of Untreated Psychosis (DUP) and Outcome in First-Episode Schizophrenia

Am J Psychiatry 2005;162:1785-1804

Purpose: To review the association between DUP and symptom severity at first treatment contact, and between DUP and treatment outcomes.

Study Characteristics: Critical review and meta-analysis of 45 studies with 4,177 patients.

Participants: Patients with non-affective psychotic disorders at or close to first treatment.

Results: Shorter DUP was associated with greater response to antipsychotic treatment, as measured by global psychopathology, positive symptoms, negative symptoms, and functional outcomes. At the time of treatment initiation, longer DUP was associated with the severity of negative symptoms but not with the severity of positive symptoms, global psychopathology, or neurocognitive function.

Conclusions: DUP may be a potentially modifiable prognostic factor.
- neuropsychology: global defects seen in attention, language, and memory suggest lack of connectivity of neural networks
- environmental: indirect evidence of cannabis use, geographical variance, winter season of birth, obstetrical complications, and prenatal viral exposure

**Pathophysiology**
- neurodegenerative theory
  - natural history may be a rapid or gradual decline in function and ability to communicate
  - glutamate system may mediate progressive degeneration by excitotoxic mechanism which leads to production of free radicals
- neurodevelopmental theory: abnormal development of the brain from prenatal life
  - neurons fail to migrate correctly, make inappropriate connections, and break down in later life
  - inappropriate apoptosis during neurodevelopment resulting in faulty connections between neurons

**Comorbidity**
- substance-related disorders
- anxiety disorders
- decreased life expectancy because of associated medical conditions (e.g. weight gain, diabetes, metabolic syndrome, CV/pulmonary disease)

**Management of Schizophrenia**
- biological
  - acute treatment and maintenance with antipsychotics ± anticonvulsants ± anxiolytics
- psychosocial
  - psychotherapy (individual, family, group): supportive, CBT
  - ACT: mobile mental health teams that provide individualized treatment in the community and help patients with medication adherence, basic living skills, social support, job placements, and community resources
  - social skills training, employment programs, disability benefits
  - housing (group home, boarding home, transitional home)

**Course and Prognosis**
- the majority of individuals display some type of prodromal phase
- course is variable: some individuals have exacerbations and remissions and others remain chronically ill; accurate prediction of the long-term outcome is not possible
- negative symptoms may be prominent early in the illness and may become more prominent and more disabling later on; positive symptoms appear and typically diminish with treatment
- over time: 1/3 improve, 1/3 remain the same, 1/3 worsen

---

### Schizophreniform Disorder

- **diagnosis**: criteria A, D, and E of schizophrenia are met; an episode of the disorder lasts for at least 1 mo but ≤6 mo
  - if the symptoms have extended past 6 mo the diagnosis becomes schizophrenia
- **specifiers**: with/without good prognostic features (e.g. acute onset, confusion, good premorbid functioning, absence of blunt/flat affect), with catatonia, current severity based on quantitative assessment of primary symptoms of psychosis
- **treatment**: similar to acute schizophrenia
- **prognosis**: better than schizophrenia; begins and ends more abruptly; good pre- and post-morbid function

---

### Brief Psychotic Disorder

- **diagnosis**: criteria A1-A4, D, and E of schizophrenia are met; an episode of the disorder lasts for at least 1 d, but <1 mo with eventual full return to premorbid level of functioning
  - **specifiers**: with/without marked stressors, with postpartum onset, with catatonia, current severity
- can occur after a stressful event or postpartum
- **treatment**: secure environment, antipsychotics, anxiolytics
- **prognosis**: good, self-limiting, should return to pre-morbid function within 1 mo
Schizoaffective Disorder

DSM-5 Diagnostic Criteria for Schizoaffective Disorder
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association
A. an uninterrupted period of illness during which there is a major mood episode concurrent with Criterion A of schizophrenia
B. delusions or hallucinations for 2 or more wk in the absence of a major mood episode during the lifetime duration of the illness
C. symptoms that meet criteria for a major mood episode are present for the majority of the total duration of the active and residual periods of the illness
D. the disturbance is not attributable to the effects of a substance or another medical condition
• specifiers: bipolar type, depressive type, with catatonia, type of episode, severity
• one-third as prevalent as schizophrenia; schizoaffective disorder bipolar type more common in young adults, schizoaffective disorder depressive type more common in older adults
• depressive symptoms correlated with higher suicide risk
• treatment: antipsychotics, mood stabilizers, antidepressants
• prognosis: between that of schizophrenia and of mood disorder

Delusional Disorder

DSM-5 Diagnostic Criteria for Delusional Disorder
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association
A. the presence of one (or more) delusions with a duration of ≥1 mo
B. criterion A for schizophrenia has never been met
Note: hallucinations, if present, are not prominent and are related to the delusional theme
C. apart from the impact of the delusion(s) or its ramifications, functioning is not markedly impaired, and behavior is not obviously bizarre or odd
D. if manic or major depressive episodes have occurred, these have been brief relative to the duration of the delusional periods
E. the disturbance is not attributable to the physiological effects of a substance or another medical condition and is not better explained by another mental disorder
• subtypes: erotomanic, grandiose, jealous, persecutory, somatic, mixed, unspecified
  ▪ further specify: bizarre content, type of episode (e.g. first episode, multiple episode), severity
• treatment: psychotherapy, antipsychotics, antidepressants
• prognosis: chronic, unremitting course but high level of functioning; a portion will progress to schizophrenia

Mood Disorders

Definitions
• mood disorders are defined by the presence of mood episodes
• mood episodes represent a combination of symptoms comprising a predominant mood state that is abnormal in quality or duration (e.g. major depressive, manic, mixed, hypomanic)
• types of mood disorders include
  ▪ depressive (major depressive disorder, persistent depressive disorder)
  ▪ bipolar (bipolar I/II disorder, cyclothymia)
  ▪ secondary to GMC, substances, medications

Medical Workup of Mood Disorder
• routine screening: physical exam, CBC, thyroid function test, electrolytes, extended electrolytes, urinalysis, drug screen
• additional screening: neurological consultation, chest x-ray, ECG, CT

Mood Episodes

DSM-5 Criteria for Major Depressive Episode
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association
A. ≥5 of the following symptoms have been present during the same 2-wk period and represent a change from previous functioning; at least one of the symptoms is either 1) depressed mood or 2) loss of interest or pleasure (anhedonia)
Note: Do not include symptoms that are clearly attributable to another medical condition
• depressed mood most of the day, nearly every day, as indicated by either subjective report or observation made by others

Non-bizarre delusions involve situations that could occur in real life (e.g. being followed, poisoned, loved at a distance)
markedly diminished interest or pleasure in all, or almost all, activities most of the day, nearly every day
significant and unintentional weight loss/weight gain, or decrease/increase in appetite nearly every day
insomnia or hypersomnia nearly every day
psychomotor agitation or retardation nearly every day
fatigue or loss of energy nearly every day
feelings of worthlessness or excessive or inappropriate guilt (which may be delusional) nearly every day (not merely self-reproach or guilt about being sick)
diminished ability to think or concentrate, or indecisiveness, nearly every day
recurrent thoughts of death (not just fear of dying), recurrent suicidal ideation without a specific plan, or a suicide attempt or a specific plan for committing suicide

B. the symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning
C. the episode is not attributable to the direct physiological effects of a substance or a GMC

**DSM-5 Criteria for Manic Episode**
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. a distinct period of abnormally and persistently elevated, expansive, or irritable mood and abnormally and persistently increased goal-directed activity or energy, lasting ≥1 wk and present most of the day, nearly every day (or any duration if hospitalization is necessary)
B. during the period of mood disturbance and increased energy or activity, ≥3 of the following symptoms have persisted (4 if the mood is only irritable) and have been present to a significant degree and represent a noticeable change from usual behavior:
   - inflated self-esteem or grandiosity
   - decreased need for sleep (e.g. feels rested after only 3 h of sleep)
   - more talkative than usual or pressure to keep talking
   - flight of ideas or subjective experience that thoughts are racing
   - distractibility (i.e. attention too easily drawn to unimportant or irrelevant external stimuli)
   - increase in goal-directed activity (either socially, at work or school, or sexually) or psychomotor agitation
   - excessive involvement in pleasurable activities that have a high potential for painful consequences (e.g. engaging in unrestrained shopping sprees, sexual indiscretions, or foolish business investments)
C. the mood disturbance is sufficiently severe to cause marked impairment in social or occupational functioning or to necessitate hospitalization to prevent harm to self or others, or there are psychotic features
D. the episode is not attributable to the physiological effects of a substance or another medical condition

Note: A full manic episode that emerges during antidepressant treatment but persists at a fully syndromal level beyond the physiological effect of that treatment is sufficient evidence for a manic episode, and therefore, a bipolar I diagnosis

Note: Criteria A-D constitute a manic episode. At least one lifetime manic episode is required for the diagnosis of bipolar I disorder

**Hypomanic Episode**
- criterion A and B of a manic episode is met, but duration is ≥4 d
- episode associated with an uncharacteristic change in functioning that is observable by others
- change in function is not severe enough to cause marked impairment in social or occupational functioning or to necessitate hospitalization
- absence of psychotic features

**Depressive Disorders**

**MAJOR DEPRESSIVE DISORDER**

**DSM-5 Diagnostic Criteria for Major Depressive Disorder (MDD), Single Episode (vs. Recurrent)**
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. presence of a single MDE (vs. recurrent, which requires presence of two or more MDEs; to be considered separate episodes, there must be an interval of at least 2 consecutive mo in which criteria are not met for a MDE)
B. the MDE is not better accounted for by schizoaffective disorder and is not superimposed on schizophrenia, schizophreniform disorder, delusional disorder, or psychotic disorder NOS
C. there has never been a manic episode or a hypomanic episode
• Note: this exclusion does not apply if all of the manic-like, or hypomanic-like episodes are substance or treatment-induced or are due to the direct physiological effects of another medical condition
• specifiers: with anxious distress, mixed features, melancholic features, atypical features, mood-congruent psychotic features, mood-incongruent psychotic features, catatonia, peripartum onset, seasonal pattern

Epidemiology
• prevalence: 12.2%
  ▪ lifetime prevalence: male 2.9%, female 5%
  ▪ annual prevalence: peak prevalence age 15-25 yr (M:F = 1:2)

Etiology
• biological
  ▪ genetic: 65-75% MZ twins; 14-19% DZ twins
  ▪ neurotransmitter dysfunction: decreased activity of SHT, NE, and DA at the level of the synapse; changes in GABA and glutamate; changes in brain circuitry
  ▪ neuroendocrine dysfunction: increased production of corticotropins causing excessive HPA axis activity
  ▪ neuroanatomy: smaller frontal lobes and hippocampal volume; increased ventricle sizes
  ▪ neurophysiologic: decreased REM latency and slow-wave sleep; increased REM length
  ▪ secondary to another medical condition
• psychosocial
  ▪ psychodynamic (e.g. low self-esteem)
  ▪ cognitive (e.g. negative thinking)
  ▪ environmental factors (e.g. job loss, bereavement, history of abuse, early life adversity)
  ▪ comorbid psychiatric diagnoses (e.g. anxiety, substance abuse, developmental disability, dementia, eating disorder)

Risk Factors
• sex: F>M
• age: onset between 25-50 yr of age
• family history: depression, alcohol abuse, sociopathy
• childhood experiences: loss of parent before age 11, negative home environment (abuse, neglect)
• personality: insecure, dependent, obsessional
• recent stressors: illness, financial, legal
• postpartum <6 mo
• lack of intimate, confiding relationships or social isolation

Treatment
• biological: antidepressants primarily; could also consider lithium, antipsychotics, anxiolytics, light therapy, ECT, rTMS
• psychological
  ▪ individual therapy (psychodynamic, interpersonal, CBT), family therapy, group therapy
  ▪ social: vocational rehabilitation, social skills training
  ▪ experimental: MST, deep brain stimulation, vagal nerve stimulation
  ▪ studies suggest CBT with pharmacotherapy results in better outcomes

Prognosis
• one year after diagnosis of a MDE without treatment: 40% of individuals still have symptoms that are sufficiently severe to meet criteria for a full MDE, 20% continue to have some symptoms that no longer meet criteria for a MDE, 40% have no mood disorder

PERSISTENT DEPRESSIVE DISORDER

DSM-5 Diagnostic Criteria for Persistent Depressive Disorder
Note: in DSM-IV-TR this was referred to as Dysthymia
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association
A. depressed mood for most of the day, for more days than not, as indicated either by subjective account or observation by others, for ≥2 yr
Note: In children and adolescents, mood can be irritable and duration must be at least 1 yr
B. presence, while depressed, of ≥2 of the following
  ▪ poor appetite or overeating
  ▪ insomnia or hypersomnia
  ▪ low energy or fatigue
  ▪ low self-esteem
  ▪ poor concentration or difficulty making decisions
  ▪ feelings of hopelessness
C. during the 2 yr period (1 yr for children or adolescents) of the disturbance, the person has never been without the symptoms in criteria A and B for more than 2 mo at a time
D. criteria for a major depressive disorder may be continuously present for 2 yr
E. there has never been a manic episode or a hypomanic episode, and criteria have never been met for cyclothymic disorder
F. the disturbance is not better explained by a persistent schizoaffective disorder, schizophrenia, delusional disorder, or other specified or unspecified schizophrenia spectrum and other psychotic disorder
G. the symptoms are not due to the direct physiological effects of a substance or another medical condition
H. the symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning

Epidemiology
- point prevalence: 3%; life prevalence: 6%; M:F = 1:2-3

Treatment
- psychological
  - principal treatment for persistent depressive disorder
  - individual, group, and family therapy
- biological
  - antidepressant therapy (SSRIs/SNRIs) as an outpatient

Bipolar Disorders

BIPOLAR I / BIPOLAR II DISORDER

Definition
- Bipolar I Disorder
  - disorder in which at least one manic episode has occurred
  - commonly accompanied by at least 1 MDE but not required for diagnosis
- Bipolar II Disorder
  - disorder in which there is at least 1 MDE and at least 1 hypomanic episode
  - no past manic or mixed episodes

Epidemiology
- prevalence: 0.6-0.9%; M:F = 1:1
- age of onset: teens to 20s

Risk Factors
- high SES
- genetic: 60-65% of bipolar patients have family history of major mood disorders

Classification
- classification of bipolar disorder involves describing the current or most recent mood episode as either manic, hypomanic, or depressed. The same specifiers for MDD can be used

Treatment
- biological: lithium, anticonvulsants, antipsychotics, ECT; monotherapy with antidepressants should be avoided
- psychological: supportive or psychodynamic psychotherapy, CBT, IPT or interpersonal social rhythm therapy, family focused treatment
- social: vocational rehabilitation, consider leave of absence from school/work, assess capacity to manage finances, drug and EtOH cessation, sleep hygiene, social skills training, education for family members

Course and Prognosis
- high suicide rate (15% mortality from suicide)
- relapsing and remitting course with alternating manic and depressive episodes; depressive symptoms tend to occur more frequently and last longer than manic episodes
- patients spend almost half of their lives symptomatic
- may switch rapidly between depression and mania without any period of euthymia in between
- high recurrence rate for mania – 90% will have a subsequent episode in the next 5 yr

Patients with bipolar disorder are at higher risk for suicide when they switch from mania to depression, especially as they become aware of consequences of their behavior during the manic episode

Treatment of bipolar depression must be done extremely cautiously, as a switch from depression to mania can result; monotherapy with antidepressants should be avoided
CYCLOTHYMIA

Diagnosis
- presence of numerous periods of hypomanic and depressive symptoms (not meeting criteria for full hypomanic episode or MDE) for ≥2 yr; never without symptoms for >2 mo
- never have met criteria for MDE, manic or hypomanic episodes
- symptoms are not due to the direct physiological effects of a substance or GMC
- symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning

Treatment
- similar to Bipolar I: mood stabilizer ± psychotherapy

Anxiety Disorders

Definition
- anxiety is a universal human characteristic involving tension, apprehension, or even terror
- serves as an adaptive mechanism to warn about an external threat by activating the sympathetic nervous system (fight or flight)
- manifestations of anxiety can be described through
  - physiology: main brain structure involved is the amygdala (fear conditioning); neurotransmitters involved include 5-HT, cholecystokinin, epinephrine, norepinephrine, DA
  - psychology: one’s perception of a given situation is distorted which causes one to believe it is threatening in some way
  - behavior: once feeling threatened, one responds by escaping or facing the situation, thereby causing a disruption in daily functioning
- anxiety becomes pathological when
  - fear is greatly out of proportion to risk/severity of threat
  - response continues beyond existence of threat or becomes generalized to other similar or dissimilar situations
  - social or occupational functioning is impaired

Differential Diagnosis

Table 2. Differential Diagnosis of Anxiety Disorders

<table>
<thead>

</tr>
</tbody>
</table>

Medical Workup of Anxiety Disorder
- routine screening: physical exam, CBC, thyroid function test, electrolytes, urinalysis, urine drug screening
- additional screening: neurological consultation, chest x-ray, ECG, CT

Panic Disorder

DSM-5 Diagnostic Criteria for Panic Disorder
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association
A. recurrent unexpected panic attacks; a panic attack is an abrupt surge of intense fear or intense discomfort that reaches a peak within minutes, and during which time four (or more) of the following symptoms occur
- palpitations, pounding heart, or accelerated heart rate
- sweating
- trembling or shaking
- sensations of shortness of breath or smothering
- feelings of choking
- chest pain or discomfort
- nausea or abdominal distress
Psyllium (Preparation A) is recommended for conditions requiring bowel regularity or treatment of constipation.

Criteria for Panic Disorder (≥4)

STUDENTS FEAR the 3 Cs
Sweating
Trembling
Unsteadiness, dizziness
Depersonalization, Derealization
Excessive heart rate, palpitations
Nausea
Tingling
Shortness of breath
Fear of dying, losing control, going crazy
3 Cs: Chest pain, Chills, Choking

Panic Attack vs. Panic Disorder
Panic disorder consists of panic attacks + other criteria
Panic attack is not a codable disorder and can occur in the context of many different disorders

Starting Medication for Anxiety
Start low, go slow, aim high and explain symptoms to expect prior to initiation of therapy

Gastrointestinal Disorders

Clinical Manifestations
- Abdominal pain
- Nausea
- Vomiting
- Changes in bowel habits (constipation, diarrhea)

Diagnosis
- Physical examination
- Laboratory tests (blood work, stool analysis, imaging studies)
- Endoscopy or colonoscopy

Treatment
- Lifestyle modifications (dietary changes, exercise)
- Medications (ant酸biotics, probiotics, prebiotics)
- Psychological interventions (cognitive-behavioral therapy)

Agoraphobia

DSM-5 Diagnostic Criteria for Agoraphobia
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association
A. marked fear or anxiety about two (or more) of the following five situations
- using public transportation
- being in open spaces
- being in enclosed places
- standing in line or being in a crowd
- being outside of the home alone
B. the individual fears or avoids these situations because of thoughts that escape might be difficult or help might not be available in the event of developing panic-like symptoms or other incapacitating or embarrassing symptoms
C. the agoraphobic situations almost always provoke fear or anxiety
D. the agoraphobic situations are actively avoided, require the presence of a companion, or are endured with intense fear or anxiety
E. the fear or anxiety is out of proportion to the actual danger posed by the agoraphobic situations and to the sociocultural context
F. the fear, anxiety, or avoidance is persistent, typically lasting for ≥6 mo
G. the fear, anxiety, or avoidance causes clinically significant distress or impairment in social, occupational, or other important areas of functioning
H. if another medical condition is present, the fear, anxiety, or avoidance is clearly excessive
I. the fear, anxiety, or avoidance is not better explained by the symptoms of another mental disorder and are not related exclusively to obsessions, perceived defects or flaws in physical appearance, reminders of traumatic events, or fear of separation

Note: agoraphobia is diagnosed irrespective of the presence of panic disorder. If an individual's presentation meets criteria for panic disorder and agoraphobia, both diagnoses should be assigned

• treatment: as per panic disorder
Generalized Anxiety Disorder

DSM-5 Diagnostic Criteria for Generalized Anxiety Disorder
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. excessive anxiety and worry (apprehensive expectation), occurring more days than not for at least 6 mo, about a number of events or activities (such as work or school performance)
B. the individual finds it difficult to control the worry
C. the anxiety and worry are associated with three (or more) of the following six symptoms (with at least some symptoms having been present for more days than not for the past 6 mo)
   1. restlessness or feeling keyed up or on edge
   2. being easily fatigued
   3. difficulty concentrating or mind going blank
   4. irritability
   5. muscle tension
   6. sleep disturbance (difficulty falling or staying asleep, or restless, unsatisfying sleep)
D. the anxiety, worry, or physical symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning
E. the disturbance is not attributable to the physiological effects of a substance or another medical condition
F. the disturbance is not better explained by another mental disorder

Epidemiology
• 1 yr prevalence: 3-8%; M:F = 1:2
  if considering only those receiving inpatient treatment, ratio is 1:1
• most commonly presents in early adulthood

Treatment
• lifestyle: caffeine and EtOH avoidance, sleep hygiene
• psychological: CBT including relaxation techniques, mindfulness
• biological
  • SSRIs and SNRIs are 1st line (paroxetine, escitalopram, sertraline, venlafaxine XL)
  • 2nd line: bupropion (caution due to stimulating effects), buspirone (tid dosing)
  • add-on benzodiazepines (short-term, low dose, regular schedule, long half-life, avoid prn)
  • β-blockers not recommended

Prognosis
• chronically anxious adults become less so with age
• depends on pre-morbid personality functioning, stability of relationships, work, and severity of environmental stress
• difficult to treat

Phobic Disorders

Specific Phobia
• definition: marked and persistent fear that is excessive or unreasonable, cued by presence or anticipation of a specific object or situation
• lifetime prevalence 12-16%; M:F ratio variable
• types: animal/insect, environment (heights, storms), blood/injection/injury, situational (airplane, closed spaces), other (loud noise, clowns)

Social Phobia (Social Anxiety Disorder)
• definition: marked and persistent fear of social or performance situations in which one is exposed to unfamiliar people or to possible scrutiny by others; fearing he/she will act in a way that may be humiliating or embarrassing (e.g. public speaking, initiating or maintaining conversation, dating, eating in public)
• 12 mo prevalence rate may be as high as 7%; F>M

Diagnostic Criteria for Phobic Disorders
• exposure to stimulus almost invariably provokes an immediate anxiety response; may present as a panic attack
• person recognizes fear as excessive or unreasonable
• situations are avoided or endured with anxiety/distress
• significant interference with daily routine, occupational/social functioning, and/or marked distress
Treatment
• psychological
  ▪ cognitive behavior therapy (focusing on both in vivo and virtual exposure therapy, gradually facing feared situations)
  ▪ behavioral therapy is more efficacious than medication
• biological
  ▪ SSRIs/SNRIs
  ▪ β-blockers or benzodiazepines in acute situations (e.g. public speaking)

Prognosis
• chronic

Obsessive-Compulsive Disorder

DSM-5 Diagnostic Criteria for Obsessive-Compulsive Disorder
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association
A. presence of obsessions, compulsions, or both
  ▪ obsessions are defined by (1) and (2)
    1. recurrent and persistent thoughts, urges, or images that are experienced, at some time during the disturbance, as intrusive and unwanted, and that in most individuals cause marked anxiety or distress
    2. the individual attempts to ignore or suppress such thoughts, urges, or images, or to neutralize them with some other thought or action (i.e. by performing a compulsion)
  ▪ compulsions are defined by (1) and (2)
    1. repetitive behaviors (e.g. hand washing, ordering, checking) or mental acts (e.g. praying, counting, repeating words silently) that the individual feels driven to perform in response to an obsession or according to rules that must be applied rigidly
    2. the behaviors or mental acts are aimed at preventing or reducing anxiety or distress, or preventing some dreaded event or situation; however, these behaviors or mental acts are not connected in a realistic way with what they are designed to neutralize or prevent, or are clearly excessive
B. the obsessions or compulsions are time-consuming (e.g. take >1 h/d) or cause clinically significant distress or impairment in social, occupational, or other important areas of functioning
C. the obsessive-compulsive symptoms are not attributable to the physiological effects
D. the disturbance is not better explained by the symptoms of another mental disorder

Epidemiology
• 12 mo prevalence 1.1-1.8%; females affected at slightly higher rates than males
• rate of OCD in first-degree relatives is higher than in the general population

Treatment
• CBT: exposure with response prevention (ERP) – involves exposure to feared situations with the addition of preventing the compulsive behaviors; cognitive strategies include challenging underlying beliefs
• pharmacotherapy: SSRIs/SNRIs, clomipramine; adjunctive risperidone

Prognosis
• tends to be refractory and chronic

Trauma- and Stressor-Related Disorders

Post-Traumatic Stress Disorder

DSM-5 Diagnostic Criteria for Post-Traumatic Stress Disorder
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association
A. exposure to actual or threatened death, serious injury, or sexual violence in one (or more) of the following ways
  1. directly experiencing the traumatic event(s)
  2. witnessing, in person, the event(s) as it occurred to others
  3. learning that the traumatic event(s) occurred to a close family member or close friend. In cases of actual or threatened death of a family member or friend, the event(s) must have been violent or accidental
  4. experiencing repeated or extreme exposure to aversive details of the traumatic event(s) (e.g. first responders collecting human remains: police officers repeatedly exposed to details of child abuse)
B. presence of one (or more) of the following intrusion symptoms associated with the traumatic event(s), beginning after the traumatic event(s) occurred
   1. recurrent, involuntary, and intrusive distressing memories of the traumatic event(s)
   2. recurrent distressing dreams in which the content and/or affect of the dream are related to the traumatic event(s)
   3. dissociative reactions (e.g. flashbacks) in which the individual feels or acts as if the traumatic event(s) were recurring
   4. intense or prolonged psychological distress at exposure to internal or external cues that symbolize or resemble an aspect of the traumatic event(s)
   5. marked physiological reactions to internal or external cues that symbolize or resemble an aspect of the traumatic event(s)

C. persistent avoidance of stimuli associated with the traumatic event(s), beginning after the traumatic event(s) occurred, as evidenced by one or both of the following
   1. avoidance of or efforts to avoid distressing memories, thoughts, or feelings about or closely associated with the traumatic event(s)
   2. avoidance of or efforts to avoid external reminders (people, places, conversations, activities, objects, situations) that arouse distressing memories, thoughts, or feelings about or closely associated with the traumatic event(s)

D. negative alterations in cognitions and mood associated with the traumatic event(s), beginning or worsening after the traumatic event(s) occurred, as evidenced by two (or more) of the following
   1. inability to remember an important aspect of the traumatic event(s)
   2. persistent and exaggerated negative beliefs or expectations about oneself, others, or the world
   3. persistent, distorted cognitions about the cause or consequences of the traumatic event(s) that lead the individual to blame himself/herself or others
   4. persistent negative emotional state (e.g. fear, horror, anger, guilt, or shame)
   5. markedly diminished interest or participation in significant activities
   6. feelings of detachment or estrangement from others
   7. persistent inability to experience positive emotions

E. marked alterations in arousal and reactivity associated with the traumatic event(s), beginning or worsening after the traumatic event(s) occurred, as evidenced by two (or more) of the following
   1. irritable behavior and angry outbursts (with little or no provocation) typically expressed as verbal or physical aggression toward people or objects
   2. reckless or self-destructive behavior
   3. hypervigilance
   4. exaggerated startle response
   5. problems with concentration
   6. sleep disturbance (e.g. difficulty falling or staying asleep or restless sleep)

F. duration of the disturbance (criteria B, C, D, and E) is >1 mo

G. the disturbance causes clinically significant distress or impairment in social, occupational, or other important areas of functioning

H. the disturbance is not attributable to the physiological effects of a substance or another medical condition

Epidemiology
- lifetime prevalence (DSM-IV criteria): 8.7%
- men’s trauma is most commonly combat experience/physical assault; women’s trauma is usually physical or sexual assault

Treatment
- CBT: exposure therapy, challenge dysfunctional beliefs, emotional regulation techniques (e.g. breathing, relaxation)
- biological
  - SSRIs
  - benzodiazepines (for acute anxiety)
  - adjunctive atypical antipsychotics (risperidone, olanzapine)
- Eye Movement Desensitization and Reprocessing (EMDR): an experimental method of reprocessing memories of distressing events by recounting them while using a form of dual attention stimulation such as eye movements, bilateral sound, or bilateral tactile stimulation (its use is controversial because of limited evidence)

Complications
- substance abuse, relationship difficulties, depression, impaired social and occupational functioning disorders, personality disorders
**Adjustment Disorder**

**DSM-5 Diagnostic Criteria for Adjustment Disorder**
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. the development of emotional or behavioral symptoms in response to an identifiable stressor(s) occurring within 3 mo of the onset of the stressor(s)

B. these symptoms or behaviors are clinically significant as evidenced by either of the following:
   - marked distress that is in excess of what would be expected from exposure to the stressor
   - significant impairment in social or occupational (academic) functioning

C. the stress-related disturbance does not meet criteria for another mental disorder and is not merely an exacerbation of a pre-existing mental disorder

D. the symptoms do not represent normal bereavement

E. once the stressor (or its consequences) has terminated, the symptoms do not persist for more than an additional 6 mo

• **specifiers**: with depressed mood, with anxiety, with mixed anxiety/depression, with conduct disturbance, with mixed disturbance of conduct/emotions, unspecified

**Classification**

- types of stressors
  - single (e.g. termination of romantic relationship)
  - multiple (e.g. marked business difficulties and marital problems)
  - recurrent (e.g. seasonal business crises)
  - continuous (e.g. living in a crime-ridden neighborhood)
  - developmental events (e.g. going to school, leaving parental home, getting married, becoming a parent, failing to attain occupational goals, retirement)

**Epidemiology**

- M=F

**Treatment**

- brief psychotherapy (group, individual), crisis intervention
- biological
  - benzodiazepines may be used for those with anxiety symptoms (short-term, low-dose, regular schedule)
  - SSRIs for both depression and anxiety symptoms

---

**Bereavement**

**Clinical Presentation**

- length and characteristics of “normal” bereavement are variable between individuals/cultures
- may present with symptoms of MDE/MDD but individual regards depressed mood as normal
- presence of following symptoms may indicate abnormal grief/presence of MDD
  - guilt about things other than actions taken or not taken by the survivor at the time of death
  - thoughts of death other than the survivor feeling that they would be better off dead or should have died with the deceased person; morbid preoccupation with worthlessness
  - marked psychomotor retardation; prolonged and marked functional impairment
  - hallucinatory experiences other than thinking that the survivor hears the voice of or transiently sees the image of the deceased person
  - after 12 mo, if patient continues to yearn/long for the deceased, experience intense sorrow/ emotional pain in response to the death, remain preoccupied with the deceased or with their circumstance of death, then may start to consider a diagnosis of “persistent complex bereavement disorder”

**Risk Factors for Poor Bereavement**

- Poor social supports
- Unanticipated death or lack of preparation for death
- Highly dependent relationship with deceased
- High initial distress
- Other concurrent stresses and losses
- Death of a child
- Pre-existing psychiatric disorders, especially depression and separation anxiety
Neurocognitive Disorders

Delirium

- see Neurology, N19 and Geriatric Medicine, GM3

DSM-5 Diagnostic Criteria for Delirium

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. a disturbance in attention (i.e. reduced ability to direct, focus, sustain, and shift attention) and awareness (reduced orientation to the environment)
B. the disturbance develops over a short period of time (usually hours to a few days), represents a change from baseline attention and awareness, and tends to fluctuate in severity during the course of a day
C. an additional disturbance in cognition (e.g. memory deficit, disorientation, language, visuospatial ability, or perception)
D. the disturbances in criteria A and C are not better explained by another preexisting, established, or evolving neurocognitive disorder and do not occur in the context of a severely reduced level of arousal, such as coma
E. there is evidence from the history, physical exam, or laboratory findings that the disturbance is a direct physiological consequence of another medical condition, substance intoxication or withdrawal (i.e. due to a drug of abuse or to a medication), or exposure to a toxin, or is due to multiple etiologies

Clinical Presentation and Assessment

- common symptoms
  - wandering attention
  - distractibility
  - disorientation (time, place, rarely person)
  - misinterpretations, illusions, hallucinations
  - speech/language disturbances (dysarthria, dysnomia, dysgraphia)
  - affective symptoms (anxiety, fear, depression, irritability, anger, euphoria, apathy)
  - shifts in psychomotor activity (grasping/picking at clothes, attempts to get out of bed when unsafe, sudden movements, sluggishness, lethargy)
- Folstein Mini Mental Status Exam is helpful to assess baseline of altered mental state (i.e. score will improve as symptoms resolve)

Risk Factors

- hospitalization (incidence 10-56%)
- nursing home residents (incidence 60%)
- polypharmacy (e.g. anticholinergic)
- childhood (e.g. febrile illness, anticholinergic use)
- old age (especially males)
- severe illness (e.g. cancer, AIDS)
- pre-existing cognitive impairment or brain pathology
- recent anesthesia
- substance abuse

Etiology (I WATCH DEATH)

- Infectious (encephalitis, meningitis, UTI, pneumonia)
- Withdrawal (alcohol, barbiturates, benzodiazepines)
- Acute metabolic disorder (electrolyte imbalance, hepatic or renal failure)
- Trauma (head injury, post-operative)
- CNS pathology (stroke, hemorrhage, tumor, seizure disorder, Parkinson’s)
- Hypoxia (anemia, cardiac failure, pulmonary embolus)
- Deficiencies (vitamin B12, folic acid, thiamine)
- Endocrinopathies (thyroid, glucose, parathyroid, adrenal)
- Acute vascular (shock, vasculitis, hypertensive encephalopathy)
- Toxins: substance use, sedatives, opioids (especially morphine), anesthetics, anticholinergics, anticonvulsants, dopamineergic agents, steroids, insulin, glyburide, antibiotics (especially quinolones), NSAIDs
- Heavy metals (arsenic, lead, mercury)

Investigations

- standard: CBC and differential, electrolytes, Ca²⁺, PO₄³⁻, Mg²⁺, glucose, ESR, LFTs, Cr, BUN, TSH, vitamin B₁₂, folate, albumin, urine C&S, R&M
- as indicated: ECG, CXR, CT head, toxicology/heavy metal screen, VDRL, HIV, LP, EEG (typically abnormal: generalized slowing or fast activity), blood cultures
- indications for CT head: focal neurological deficit, acute change in status, anticoagulant use, acute incontinence, gait abnormality, history of cancer
Management

- intrinsic
  - identify and treat underlying cause immediately
  - stop all non-essential medications
  - maintain nutrition, hydration, electrolyte balance and monitor vitals

- extrinsic
  - environment should be quiet and well lit
  - optimize hearing and vision
  - room near nursing station for closer observation; constant care if patient jumping out of bed, pulling out lines
  - family member present for reassurance and re-orientation
  - calendar, clock for orientation cues

- biological
  - low dose antipsychotics
  - haloperidol has the most evidence; reasonable alternatives include risperidone, olanzapine, or quetiapine
  - benzodiazepines only to be used in alcohol withdrawal delirium; otherwise, can worsen delirium

- physical restraints if patient becomes violent

Prognosis

- up to 50% 1 yr mortality rate after episode of delirium

Major Neurocognitive Disorder/Dementia

- see Neurology. N19

DSM-5 Diagnostic Criteria for Major Neurocognitive Disorder

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. evidence of significant cognitive decline from a previous level of performance in one or more cognitive domains (complex attention, executive function, learning and memory, language, perceptual-motor, or social cognition) based on
   1. concern of the individual, a knowledgeable informant, or the clinician that there has been a significant decline in cognitive function;
   2. a substantial impairment in cognitive performance, preferably documented by standardized neuropsychological testing or, in its absence, another quantified clinical assessment

B. the cognitive deficits interfere with independence in everyday activities (i.e. at a minimum, requiring assistance with complex instrumental activities of daily living such as paying bills or managing medications)

C. the cognitive deficits do not occur exclusively in the context of a delirium

D. the cognitive deficits are not better explained by another mental disorder (e.g. major depressive disorder, schizophrenia)

• specify whether due to
  - Alzheimer’s disease
  - Traumatic brain injury
  - Huntington’s disease
  - Frontotemporal lobar degeneration
  - Substance/medication use
  - Another medical condition
  - Lewy body disease
  - HIV infection
  - Multiple etiologies
  - Vascular disease
  - Prion disease
  - Unspecified

Epidemiology

- prevalence increases with age: 10% in patients >65 yr of age; 25% in patients >85 yr of age
- prevalence is increased in people with Down’s syndrome and head trauma
- Alzheimer’s disease comprises >50% of cases; vascular causes comprise approximately 15% of cases (other causes of dementia neurocognitive disorder – see Neurology. N19)
- average duration of illness from onset of symptoms to death is 8-10 yr

Subtypes

- with or without behavioral disturbance (e.g. wandering, agitation)
- early onset: age of onset <65 yr
- late onset: age of onset >65 yr

Investigations (Rule Out Reversible Causes)

• standard: see Delirium
• as indicated: VDRL, HIV, SPECT, CT head in dementia
indications for CT head: same as for delirium, plus: age <60, rapid onset (unexplained decline in cognition or function over 1-2 mo), dementia of relatively short duration (<2 yr), recent significant head trauma, unexplained neurological symptoms (new onset of severe headache/seizures)

Management
- see Neurology, N22 for further management
- treat underlying medical problems and prevent others
- provide orientation cues for patient (e.g. clock, calendar)
- provide education and support for patient and family (e.g. day programs, respite care, support groups, home care)
- consider long-term care plan (nursing home) and power of attorney/living will
- inform Ministry of Transportation about patient’s inability to drive safely
- consider pharmacological therapy
  - cholinesterase inhibitors (e.g. donepezil [Aricept®]) for mild to severe disease
  - NMDA receptor antagonist (e.g. memantine) for moderate to severe disease
  - low-dose neuroleptics (e.g. risperidone, quetiapine), antidepressants or trazodone if behavioral or emotional symptoms prominent – start low and go slow
  - reassess pharmacological therapy every 3 mo

Substance-Related and Addictive Disorders

Epidemiology
- 47% of those with substance abuse have mental health problems
- 29% of those with a mental health disorder have a substance use disorder
- 47% of those with schizophrenia and 25% of those with an anxiety disorder have a substance use disorder

Substance Use Disorders
- substance use disorders are measured on a continuum from mild to severe; 2-3 criteria is required for a mild substance use disorder diagnosis, 4-5 is moderate, and 6-7 is severe
- each specific substance can be addressed as a separate use disorder (e.g. alcohol use disorder, stimulant use disorder) and diagnosed utilizing the same overarching criteria
- criteria for substance use disorders
  - hazardous use
- social/interpersonal problems related to use
- neglected major roles to use
- withdrawal
- tolerance
- use large amounts/longer
- repeated attempts to quit/control use
- use for longer duration/larger amount than intended
- physical/psychological problems related to use
- activities given up to use
- cravings

### Classification of Substances

<table>
<thead>
<tr>
<th>Depressants</th>
<th>Alcohol, Opioids, Barbiturates, Benzodiazepines, GHB</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stimulants</td>
<td>Amphetamines, Methylphenidate, Cocaine</td>

<tr>
<td>Hallucinogens</td>
<td>Cannabis, LSD, PCP, Ketamine, Psilocybin</td>
</tr>
</tbody>
</table>

### Nicotine

- see Family Medicine, FM10

### Alcohol

- see Family Medicine, FM12 and Emergency Medicine, ER53

#### History

- CAGE: validated screening questionnaire
  - C: ever felt the need to Cut down on drinking?
  - A: ever felt Annoyed at criticism of your drinking?
  - G: ever feel Guilty about your drinking?
  - E: ever need a drink first thing in morning (Eye opener)?

- if positive CAGE, then assess further to distinguish between problem drinking and alcohol dependence

#### General Assessment

- When was your last drink?
- Do you have to drink more to get the same effect?
- Do you get shaky or nauseous when you stop drinking?
- Have you ever had a withdrawal seizure?
- How much time and effort do you put into obtaining alcohol?
- Has your drinking affected your ability to work, go to school, or have relationships?
- Have you suffered any legal consequences?
- Has your drinking caused any medical problems?

#### Table 4. Canada’s Low-Risk Alcohol Drinking Guidelines

<table>
<thead>
<tr>
<th>Moderate Drinking</th>
</tr>
</thead>
<tbody>
<tr>
<td>Men: 3 or less/d (≤15/wk)</td>
</tr>
<tr>
<td>Women: 2 or less/d (≤10/wk)</td>
</tr>
<tr>
<td>Elderly: 1 or less/d</td>
</tr>
</tbody>
</table>

#### Alcohol Intoxication

- legal limit for impaired driving is 10.6 mmol/L (50 mg/dL) reached by 2-3 drinks/h for men and 1-2 drinks/h for women
- coma can occur with >60 mmol/L (non-tolerant drinkers) and 90-120 mmol/L (tolerant drinkers)

#### Alcohol Withdrawal

- occurs within 12-48 h after prolonged heavy drinking and can be life-threatening
- alcohol withdrawal can be described as having 4 stages, however not all stages may be experienced
  - stage 1 (onset 12-18 h after last drink): “the shakes” tremor, sweating, agitation, anorexia, cramps, diarrhea, sleep disturbance
  - stage 2 (onset 7-38 h): alcohol withdrawal seizures, usually tonic-clonic, nonfocal and brief
  - stage 3 (onset 48 h): visual, auditory, olfactory or tactile hallucinations
  - stage 4 (onset 3-5 d): delirium tremens, confusion, delusions, hallucinations, agitation, tremors, autonomic hyperactivity (fever, tachycardia, HTN)
- course: almost completely reversible in young; elderly often left with cognitive deficits
- mortality rate 20% if untreated

#### Delirium Tremens

- (Alcohol Withdrawal Delirium)
  - Autonomic hyperactivity (diaphoresis, tachycardia, increased respiration)
  - Hand tremor
  - Insomnia
  - Psychomotor agitation
  - Anxiety
  - Nausea or vomiting
  - Tonic-clonic seizures
  - Visual/tactile/auditory hallucinations
  - Persecutory delusions
Management of Alcohol Withdrawal
- monitor using the Clinical Institute Withdrawal Assessment for Alcohol (CIWA-A) scoring system
  - areas of assessment include
    - nausea and vomiting
    - tactile disturbances
    - tremor
    - auditory disturbances
    - agitation
    - paroxysmal sweats
    - visual disturbances
    - anxiety
    - headache, fullness in head
    - orientation and clouding of sensorium
  - all categories are scored from 0-7 (except: orientation/sensorium 0-4), maximum score of 67
    - mild <10
    - moderate 10-20
    - severe >20

Wernicke-Korsakoff Syndrome
- alcohol-induced amnestic disorders due to thiamine deficiency
- necrotic lesions: mamillary bodies, thalamus, brainstem
- Wernicke's encephalopathy (acute and reversible): triad of nystagmus (CN VI palsy), ataxia, and confusion
- Korsakoff's syndrome (chronic and only 20% reversible with treatment): anterograde amnesia and confabulations; cannot occur during an acute delirium or dementia and must persist beyond usual duration of intoxication/withdrawal
- management
  - Wernicke's: thiamine 100 mg PO OD x 1-2 wk
  - Korsakoff's: thiamine 100 mg PO bid/tid x 3-12 mo

Treatment of Alcohol Use Disorder
- non-pharmacological
  - psychotherapy: motivational enhancement therapy (MET; increasing motivation to change), CBT (assertiveness training, increasing social support, planning leisure activities), marital and family therapy
  - behavior therapy: contingency management, community reinforcement approach (CRA)
  - supportive services: counseling, detoxification centers, Alcoholics Anonymous
  - inpatient programs (e.g. 28-day programs)
    - individual readiness for change must always be considered with non-pharmacological interventions (see Prochaska's Stages of Change Model, Population Health and Epidemiology, PH6)
- pharmacological
  - naltrexone (Revia®): opioid antagonist, shown to be successful in reducing the “high” associated with alcohol, moderately effective in reducing cravings, frequency or intensity of alcohol binges
  - disulfiram (Antabuse®): blocks oxidation of alcohol (blocks acetaldehyde dehydrogenase); with alcohol consumption, acetaldehyde accumulates to cause a toxic reaction (vomiting, tachycardia, death); if patient relapses, must wait 48 h before restarting Antabuse®
  - acamprosate (Campral®): NMDA glutamate receptor antagonist; useful in maintaining abstinence and decreasing cravings
**Opioids**

- types of opioids: heroin, morphine, oxycodone, Tylenol #3® (codeine), hydromorphone
- major risks associated with the use of contaminated needles: increased risk of hepatitis B and C, bacterial endocarditis, HIV/AIDS

**Acute Intoxication**
- direct effect on receptors in CNS resulting in decreased pain perception, sedation, decreased sex drive, nausea/vomiting, decreased GI motility (constipation and anorexia), and respiratory depression

**Toxic Reaction**
- typical syndrome includes shallow respirations, miosis, bradycardia, hypothermia, decreased level of consciousness
- management:
  - ABCs
  - IV glucose
  - naloxone hydrochloride (Narcan®): 0.4 mg up to 2 mg IV for diagnosis
  - treatment: intubation and mechanical ventilation, ± naloxone drip, until patient alert without naloxone (>48 h with long-acting opioids)
- caution with longer half-life; may need to observe for toxic reaction for at least 24 h

**Withdrawal**
- symptoms: depression, insomnia, drug-craving, myalgias, nausea, chills, autonomic instability (lacrimation, rhinorrhea, piloerection)
- onset: 6-12 h; duration: 5-10 d
- complications: loss of tolerance (overdose on relapse), miscarriage, premature labor
- management: long-acting oral opioids (methadone, buprenorphine), α-adrenergic agonists (clonidine)

**Treatment of Opioid Use Disorder**
- psychosocial treatment (e.g. Narcotics Anonymous) usually emphasize total abstinence
- naltrexone or naloxone (opioid antagonists) may also be used to extinguish drug-seeking behavior
- long-term treatment may include withdrawal maintenance treatment with methadone or buprenorphine
- Suboxone® formulation includes naloxone in addition to buprenorphine, in an effort to prevent injection of the drug. When naloxone is injected, it will precipitate opiate withdrawal and block the opiate effect of buprenorphine, however it will not have this antagonist action when taken sublingually

**Cocaine**

- street names: blow, C, coke, crack, flake, freebase, rock, snow
- alkaloid extracted from leaves of the coca plant; blocks presynaptic uptake of dopamine (causing euphoria), norepinephrine and epinephrine (causing vasospasm, HTN)
- self-administered by inhalation or intravenous route

**Intoxication**
- elation, euphoria, pressured speech, restlessness, sympathetic stimulation (e.g. tachycardia, mydriasis, sweating)
- prolonged use may result in paranoia and psychosis

**Overdose**
- medical emergency: HTN, tachycardia, tonic-clonic seizures, dyspnea, and ventricular arrhythmias
- treatment with IV diazepam to control seizures and propanolol or labetalol to manage HTN and arrhythmias

**Withdrawal**
- initial “crash” (1-48 h): increased sleep, increased appetite
- withdrawal (1-10 wk): dysphoric mood plus fatigue, irritability, vivid unpleasant dreams, insomnia or hypersonnia, psychomotor agitation or retardation
- complications: relapse, suicide (significant increase in suicide during withdrawal period)
- management: supportive management

**Treatment of Cocaine Use Disorder**
- psychotherapy, group therapy, NA, and behavior modification useful in maintaining abstinence

**Opioid Antagonists: Naltrexone vs. Naloxone**
- Naltrexone (Revia®)
  - Used for opioid and EtOH dependence
  - Long half life (h)
- Naloxone (Narcan®):
  - Used for life-threatening CNS/respiratory depression in opioid overdose
  - Short half life (<1 h)
  - Very fast acting (min)
  - High affinity for opioid receptor
  - Induces opioid withdrawal symptoms

**Common Presentations of Drug Use**

</tbody>
</table>
Complications
• cardiovascular: arrhythmias, MI, CVA, ruptured AAA
• neurologic: seizures
• psychiatric: psychosis, paranoia, delirium, suicidal ideation

Amphetamines
• intoxication characterized by euphoria, improved concentration, sympathetic and behavioral hyperactivity and at high doses can cause coma
• chronic use can produce a paranoid psychosis which can resemble schizophrenia with agitation, paranoia, delusions and hallucinations
• withdrawal symptoms include dysphoria, fatigue, and restlessness
• treatment of stimulant psychosis: antipsychotics

Cannabis
• cannabis (marijuana) is the most commonly used illicit drug
• psychoactive substance: delta-9-tetrahydrocannabinol (Δ9-THC)
• intoxication characterized by tachycardia, conjunctival vascular engorgement, dry mouth, altered sensorium, increased appetite, increased sense of well-being, euphoria/lahughter, muscle relaxation, impaired performance on psychomotor tasks including driving
• high doses can cause depersonalization, paranoia, anxiety and may trigger psychosis and schizophrenia if predisposed
• chronic use associated with tolerance and an apathetic, amotivational state
• cessation does produce a significant withdrawal phenomenon
• treatment of cannabis use disorder: behavioral and psychological interventions to maintain an abstinent state

Hallucinogens
• types of hallucinogens: LSD, mescaline, psilocybin mushrooms, PCP, salvia
• LSD is a highly potent drug; intoxication characterized by tachycardia, HTN, mydriasis, tremor, hyperpyrexia, and a variety of perceptual and mood changes
• high doses can cause depersonalization, paranoia, and anxiety
• no specific withdrawal syndrome characterized
• treatment of agitation and psychosis: support, reassurance, diminished stimulation; benzodiazepines or high potency antipsychotics seldom required

“Club Drugs”

<table>
<thead>
<tr>
<th>Drug</th>

</tr>
</tbody>
</table>

Date Rape Drugs
• GHB
• Flunitrazepam (Rohipnol®)
• Ketamine

Formication
Tactile hallucination that insects or snakes are crawling over or under the skin (especially associated with crystal meth use)

Pharm Party
An increasing trend among teenagers where assorted prescription medications are brought to a party and ingested at random

Medical Uses of Marijuana
• Anorexia-cachexia (AIDS, cancer)
• Spasticity, muscle spasms (multiple sclerosis, spinal cord injury)
• Levodopa-induced dyskinesia (Parkinson’s Disease)
• Controlling tics and obsessive-compulsive behavior (Tourette’s syndrome)
• Reducing intra-ocular pressure (glaucoma)

Cannabis Use and Risk of Psychotic or Affective Mental Health Outcomes: A Systematic Review
The Lancet 2007;310:319-320
Purpose: To review the evidence for cannabis use and occurrence of psychotic or affective mental health outcomes.
Study Characteristics: A meta-analysis of 35 population-based longitudinal studies, or case-control studies nested within longitudinal designs.
Results: There was an increased risk of any psychotic outcome in individuals who had ever used cannabis (pooled adjusted odds ratio = 1.41, 95% CI 1.30-1.53). Findings were consistent with a dose-response effect, with greater risk in people who used cannabis more frequently (2.09, 95% CI 1.54-2.84). Findings for depression, suicidal thoughts, and anxiety outcomes were less consistent. In both cases (psychotic and affective outcomes), a substantial confounding effect was present.
Conclusions: The findings are consistent with the view that cannabis increases risk of psychotic outcomes independent of transient intoxication effects, although evidence is less strong for affective outcomes. Although cannabis use and the development of psychosis are strongly associated, it is difficult to determine causality and it is possible that the association results from confounding factors or bias. The authors did conclude that there is sufficient evidence to warn young people that using cannabis could increase their risk of developing a psychiatric illness later in life.

</tbody>
</table>

Somatic Symptom and Related Disorders

General Characteristics
- Physical signs and symptoms lacking a known medical basis in the presence of psychological factors that are judged to be important in the initiation, exacerbation, or maintenance of the disturbance
- Cause significant distress or impairment in functioning
- Symptoms are produced unconsciously and are not the result of malingering or factitious disorder
- Primary gain: somatic symptom represents a symbolic resolution of an unconscious psychological conflict; serves to reduce anxiety and conflict with no external incentive
- Secondary gain: the sick role; external benefits obtained or unpleasant duties avoided (e.g. work)

Management of Somatic Symptom and Related Disorders
- Brief frequent visits
- Limit number of physicians involved in care
- Focus on psychosocial not physical symptoms
- Minimize medical investigations; coordinate necessary investigations
- Psychotherapy: CBT, biofeedback, conflict resolution
- Minimize psychotropic drugs: anxiolytics in short-term only, antidepressants for depressive and anxiety symptoms

Somatic Symptom Disorder

DSM-5 Diagnostic Criteria for Somatic Symptom Disorder
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association
A. One or more somatic symptoms that are distressing or result in significant disruption of daily life
B. Excessive thoughts, feelings, or behaviors related to the somatic symptoms or associated health concerns as manifested by at least one of the following
   1. Disproportionate and persistent thoughts about the seriousness of one’s symptoms
   2. Persistently high level of anxiety about health or symptoms
   3. Excessive time and energy devoted to these symptoms or health concerns
C. Although any one somatic symptom may not be continuously present, the state of being symptomatic is persistent (typically >6 mo)
- Symptoms may or may not be associated with another medical condition
- Lifetime prevalence may be around 5-7% in the general adult population
- Females tend to report more somatic symptoms than males do, cultural factors may influence sex ratio
- Complications: anxiety, depression, unnecessary medications or surgery
- Often a misdiagnosis for an insidious illness so rule out all organic illnesses (e.g. multiple sclerosis)
Illness Anxiety Disorder (formerly Hypochondriasis)

- preoccupation with fear of having, or the idea that one has, a serious disease based on a misinterpretation of one or more bodily signs or symptoms
- evidence does not support diagnosis of a physical disorder
- fear of having a disease despite medical reassurance
- belief is not of delusional intensity (as in delusional disorder, somatic type) as person acknowledges unrealistic interpretation
- duration is ≥6 mo; onset in 3rd-4th decade of life
- community prevalence 1.1-4.5%; prevalence in general medical practice 4-9%; higher in psychiatric settings
- role for SSRIs due to anxiety

Conversion Disorder
(Functional Neurological Symptom Disorder)

- one or more symptoms or deficits affecting voluntary motor or sensory function that mimic a neurological or GMC (e.g. impaired co-ordination, local paralysis, double vision, seizures, or convulsions)
- does not need to be preceded by a psychological event as per previous DSM criteria
- 2-5/100,000 in general population; 5% of referrals to neurology clinics
- more common in rural populations and in individuals with little medical knowledge
- spontaneous remission in 95% of acute cases, 50% of chronic cases (>6 mo)

Dissociative Disorders

Definition
- dissociation so severe that the usually integrated functions of consciousness and perception of self break down
- sudden or gradual onset, transient or chronic course
- symptoms cause distress or impaired functioning
- differential diagnosis: PTSD, acute stress disorder, somatization disorder, substance abuse, GMC (e.g. complex/partial seizures)

Table 7. Dissociative Disorders

<table>
<thead>
<tr>
<th>Amnesia</th>
<th>Fugue</th>
<th>Identity Disorder</th>
<th>Depersonalization/Derealization Disorder</th>
</tr>

<tbody>
<tr>
<td>Diagnosis</td>
<td>Inability to recall important personal information, usually of a traumatic or stressful nature; may be localized, selective, or generalized.</td>
<td>Sudden, unexpected travel away from home or workplace with inability to recall some or all of one’s past; may assume new identity.</td>
<td>Two or more distinct personalities that take control of an individual’s behavior; amnesia regarding personal history (i.e. Multiple Personality Disorder).</td>
</tr>
<tr>
<td>Epidemiology</td>
<td>6% prevalence of increased survivors of trauma (war, abuse).</td>
<td>0.2% prevalence. May occur under traumatic circumstances (combat, rape, natural disasters).</td>
<td>1.3% prevalence, M:F=1:3.9. May have history of physical or sexual abuse.</td>
</tr>
</tbody>
</table>

Sleep Disorders

- see Neurology, N45

Criteria for Diagnosis
- causes significant distress or impairment in functioning
- not due to medications, drugs, or a GMC
**Nocturnal Myoclonus**
- middle-aged and elderly
- myoclonic jerks every 20-40 s
- bed partner complaints
- treatment: benzodiazepines (clonazepam, nitrazepam)

**Narcolepsy**
- see Neurology, N47

**Primary Insomnia**
- see Family Medicine, FM47

**Sleep Apnea**
- see Respirology, R31

**Sexuality and Gender**

**Gender Dysphoria**
- refers to the distress that may coincide with conflict between one's experienced/expressed gender and one's assigned gender
- **typical presentation**
  - strong and persistent cross-gender identification
  - desire to be rid of primary/secondary sex characteristics and to gain the primary/secondary sex characteristics of their identified gender
  - repeated stated desire or insistence that one is of the opposite sex
  - preference for cross-dressing, cross-gender roles in make-believe play
  - intense desire to participate in the stereotypical games and pastimes of the opposite sex
  - strong preference for playmates of the opposite sex
  - significant distress or impairment in functioning and persistent discomfort with his or her sex or gender role
- **treatment**
  - psychotherapy
  - hormonal therapy
  - sexual reassignment surgery

**Paraphilic Disorders**
- **definition**: intense and persistent sexual interest other than sexual interest in genital stimulation or preparatory fondling with phenotypically normal, physically mature, consenting human partners
- **paraphilic disorder**: paraphilia that causes distress or functional impairment to the individual, or a paraphilia whose realization entails personal harm, or risk of harm to others
- **subtypes**: voyeuristic, exhibitionistic, frotteuristic, sexual masochism, sexual sadism, pedophilic, fetishistic, transvestic, other specified paraphilic disorder, unspecified paraphilic disorder
- rarely self-referred; come to medical attention through interpersonal or legal conflict
- person usually has more than one paraphilia; 5% of paraphilias attributed to women
- **typical presentation**
  - begins in childhood or early adolescence; increasing in complexity and stability with age
  - chronic, decreases with advancing age but may increase with stress
- **treatment**
  - anti-androgen drugs
  - behavior modification
  - psychotherapy

**SEXUAL DYSFUNCTION**
- see Gynecology, GY30 and Urology, U30
Eating Disorders

Epidemiology
- anorexia nervosa (AN): 1% of adolescent and young adult females; onset 13-20 yr old
- bulimia nervosa (BN): 2-4% of adolescent and young adult females; onset 16-18 yr old
- F:M=10:1; mortality 5-10%

Etiology
- multifactorial: psychological, sociological, and biological associations
- individual: perfectionism, lack of control in other life areas, history of sexual abuse
- personality: obsessive-compulsive, histrionic, borderline
- familial: maintenance of weight equilibrium and control in dysfunctional family
- cultural factors: prevalent in industrialized societies, idealization of thinness in the media
- genetic factors
  - AN: 6% prevalence in siblings, with one study of twin pairs finding concordance in 9 of 12 monozygotic pairs vs. concordance in 1 of 14 dizygotic pairs
  - BN: higher familial incidence of affective disorders than the general population

Risk Factors
- physical factors: obesity, chronic medical illness (e.g. DM)
- psychological factors: individuals who by career choice are expected to be thin, family history (mood disorders, eating disorders, substance abuse), history of sexual abuse, homosexual males, competitive athletes, concurrent associated mental illness (depression, OCD, anxiety disorder [especially panic and agoraphobia], substance abuse [specifically for BN])

Anorexia Nervosa

DSM-5 Diagnostic Criteria for Anorexia Nervosa
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association
A. restriction of energy intake relative to requirements, leading to a significantly low body weight in the context of age, sex, developmental trajectory, and physical health. Significantly low weight is defined as a weight that is less than minimally normal or, for children and adolescents, less than that minimally expected
B. intense fear of gaining weight or of becoming fat, or persistent behavior that interferes with weight gain, even though at a significantly low weight
C. disturbance in the way in which one’s body weight or shape is experienced, undue influence of body weight or shape on self-evaluation, or persistent lack of recognition of the seriousness of the current low body weight
- specifiers: partial remission, severity based on BMI (mild = BMI >17 kg/m², moderate = BMI 16-16.99 kg/m², severe = BMI 15-15.99 kg/m², extreme = BMI <15 kg/m²), type (restricting = during last 3 mo no episodes of binge-eating or purging vs. binge-eating/purging type = in last 3 mo have participated in recurrent episodes of binge-eating/purging)

Management
- outpatient programs and inpatient programs are available
- inpatient hospitalization for treatment of eating disorders is rarely on an acute basis (unless there is a concurrent psychiatric reason for emergent admission e.g. suicide risk)
- admit to a medical ward for hospitalization: <65% of standard body weight (<85% of standard body weight for adolescents), hypovolemia requiring intravenous fluid, heart rate <40 bpm, abnormal serum chemistry or if actively suicidal
- agree on target body weight on admission and reassure this weight will not be surpassed
- psychotherapy (individual/group/family): address food and body perception, coping mechanisms, health effects
- monitor for complications of AN (see Table 8)
- monitor for refeeding syndrome
  - a potentially life-threatening metabolic response to refeeding in severely malnourished patients resulting in severe shifts in fluid and electrolyte levels
  - complications include hypophosphatemia, congestive heart failure, cardiac arrhythmias, delirium, and death
  - prevention: slow refeeding, gradual increase in nutrition, supplemental phosphorus, close monitoring of electrolytes and cardiac status
Prognosis
• early intervention much more effective (adolescent onset has much better prognosis than adult onset)
• 1 in 10 adolescents continue to have anorexia nervosa as adults
• with treatment, 70% resume a weight of at least 85% of expected levels and about 50% resume normal menstrual function
• eating peculiarities and associated psychiatric symptoms are common and persistent
• long-term mortality: 10-20% of patients hospitalized will die in next 10-30 yr (secondary to severe and chronic starvation, metabolic or cardiac catastrophes, with a significant proportion committing suicide)

Bulimia Nervosa

DSM-5 Diagnostic Criteria for Bulimia Nervosa
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association
A. recurrent episodes of binge-eating; an episode of binge-eating is characterized by both of the following
• eating, in a discrete period of time, an amount of food that is definitely larger than what most individuals would eat during a similar period of time and under similar circumstances
• a sense of lack of control over eating during the episode
B. recurrent inappropriate compensatory behavior in order to prevent weight gain, such as self-induced vomiting; misuse of laxatives, diuretics, enemas, or other medications, fasting, or excessive exercise
C. the binge-eating and inappropriate compensatory behaviors both occur, on average, at least once a week for 3 mo
D. self-evaluation is unduly influenced by body shape and weight
E. the disturbance does not occur exclusively during episodes of AN
• specifiers: partial remission, full remission, severity (mild = 1-3 inappropriate compensatory behaviors/wk, moderate = 4-7 inappropriate compensatory behaviors/wk, severe = 8-13 inappropriate compensatory behaviors/wk, extreme = 14+ inappropriate compensatory behaviors/wk)

Associated Features
• fatigue and muscle weakness due to repetitive vomiting and fluid/electrolyte imbalance
• tooth decay
• swollen appearance around angle of jaw and puffiness of eye sockets due to fluid retention
• reddened knuckles, Russell's sign (knuckle callus from self-induced vomiting)
• trouble concentrating
• weight fluctuation over time

Management
• admission for significant electrolyte abnormalities
• biological: treatment of starvation effects, SSRIs
• psychological: develop trusting relationship with therapist to explore personal etiology and triggers, CBT, family therapy, recognition of health risks
• social: challenge destructive societal views of women, use of hospital environment to provide external patterning for normative eating behavior

Prognosis
• relapsing/remitting disease
• good prognostic factors: onset before age 15, achieving a healthy weight within 2 yr of treatment
• poor prognostic factors: later age of onset, previous hospitalizations, individual and familial disturbance
• 60% good treatment outcome, 30% intermediate outcome, 10% poor outcome

Avoidant/Restrictive Food Intake Disorder
• definition: eating/feeding disturbance to the point that there is persistent failure to meet appropriate nutritional and/or energy needs such that individual experiences significant weight loss/growth failure, have nutritional deficiencies, may become dependent on enteral feeding/oral nutritional supplementation, has a marked interference with psychosocial functioning
• risk factors: temperament (e.g. anxiety disorders), environment (e.g. familial anxiety), genetic (e.g. history of GI conditions)
• begins in infancy and can persist into adulthood
• treatment
  ▪ watchful waiting
  ▪ behavior modification
  ▪ psychotherapy
Binge-Eating Disorder

- **definition:** recurrent episodes of binge-eating (as defined by criteria A of BN) that are associated with eating much more rapidly than normal, eating until feeling uncomfortably full, eating large amounts when not physically hungry, eating alone because embarrassed by how much one is eating, feeling disgusted with oneself/depressed/very guilty afterwards at least once/wk x 3 mo
- not associated with any compensatory behaviors
- dieting usually follows binge-eating (vs. BN where dysfunctional dieting typically precedes binge-eating)
- **epidemiology:** F:M = 2:1
- associated with health consequences (e.g. increased risk of weight gain, obesity)
- begins in adolescence or young-adulthood
- hallmark of treatment is CBT

Personality Disorders

- an evolving personality disorder literature describes that personality is better understood using a trait-based dimensional approach rather than discrete categories, however the discrete categories still remain in the current DSM and will be referenced here

**General Diagnostic Criteria**

- an enduring pattern of inner experience and behavior that deviates markedly from the expectations of the individual’s culture; manifested in two or more of: cognition, affect, interpersonal functioning, impulse control
- inflexible and pervasive across a range of situations
- pattern is stable and well established by adolescence or early adulthood
- associated with many complications, such as depression, suicide, violence, brief psychotic episodes, multiple drug use, and treatment resistance
- the mainstay of treatment is psychotherapy with the addition of pharmacotherapy to treat associated axis I disorders (i.e. depression, anxiety, substance abuse)
- main treatment for borderline personality disorder is dialectical behavioral therapy (consists of validating rather than blaming the patient, and replacing maladaptive behavior with adaptive behavior)

**Borderline Personality Disorder**

**DESPAIRER**
- Disturbance of identity
- Emotionally labile
- Suicidal behavior
- Paranoid or dissociation
- Abandonment (fear of)
- Impulsive
- Relationships unstable
- Emptiness (feelings of)
- Rage (inappropriate)

*Created by Jason Caplan, MD

**Antisocial Personality Disorder**

**CORRUPT**
- Cannot conform to law
- Obligations ignored
- Reckless disregard for safety
- Remorselessness
- Underhanded (deceitful)
- Planning insufficient (impulsive)
- Temper (irritable and aggressive)
### Table 9. Classification and Diagnosis of Personality Disorders

**Note:** For each personality disorder, the most recognizable feature is indicated in italics.

<table>
<thead>
<tr>
<th>Diagnostic Cluster</th>
<th>Cluster A “Mad”</th>
<th>Cluster B “Bad”</th>
</tr>
</thead>
<tbody>
<tr>
<td>Patients seem odd, eccentric, withdrawn</td>
<td>Paranoid Personality Disorder (0.5-3%)</td>
<td>Borderline Personality Disorder (2-4%)</td>

<td>Schizoid Personality Disorder</td>
<td>Narcissistic Personality Disorder (2%)</td>
</tr>
<tr>
<td>Pattern of eccentric behaviors, peculiar thought patterns Diagnosis requires 5 of:</td>
<td>Neither desires nor enjoys close relationships including being a part of a family; prefers to be alone. Lifelong pattern of social withdrawal. Seen as eccentric and reclusive with restricted affect. Diagnosis requires 4 of:</td>
<td>Sense of superiority, needs constant admiration, lacks empathy, but with fragile sense of self Consider themselves “special” and will exploit others for personal gain Diagnosis requires 5 of:</td>
</tr>
<tr>
<td></td>
<td>1. Ideas of reference</td>
<td>1. Exaggerated sense of self-importance (grandiosity)</td>
</tr>
<tr>
<td></td>
<td>2. Odd beliefs, magical thinking (inconsistent with cultural norms e.g. belief in telepathy, superstitions)</td>
<td>2. Preoccupied with fantasies of unlimited success, power, beauty, love</td>
</tr>
<tr>
<td></td>
<td>3. Unusual perceptual experiences (e.g. bodily illusions)</td>
<td>3. Believes he/she is “special” and should associate with other “special” people</td>
</tr>
<tr>
<td></td>
<td>4. Suspiciousness</td>
<td>4. Requires excessive admiration</td>
</tr>
<tr>
<td></td>
<td>5. Inappropriate or restricted affect</td>
<td>5. Sense of entitlement</td>
</tr>
<tr>
<td></td>
<td>6. Odd, eccentric appearance or behavior (e.g. involved in cults, strange religious practices)</td>
<td>6. Takes advantage of others</td>
</tr>
<tr>
<td></td>
<td>7. Few close friends</td>
<td>7. Lacks empathy</td>
</tr>
<tr>
<td></td>
<td>8. Odd thinking, odd speech (e.g. vague, stereotyped)</td>
<td>8. Envious of others or believes that others are envious of him/her</td>
</tr>
<tr>
<td>Schizoid Personality Disorder</td>
<td></td>
<td>Antisocial Personality Disorder (M: 3%, F: 1%)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Lack of remorse for actions, manipulative and deceitful, often violate the law. May appear charming on first impression. Pattern of disregard for others and violation of rights of others must be present before the age of 15; however, for the diagnosis of ASPD patients must be at least 18. Diagnosis requires 3 of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1. Failure to conform to social norms by committing unlawful acts</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2. Deceitfulness, lying, manipulating others for personal gain</td>

<th>Obsessive-Compulsive Personality Disorder (3-10%)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Timid and socially awkward with a pervasive sense of inadequacy and fear of criticism. Fear of embarrassing or humiliating themselves in social situations so remain withdrawn and socially inhibited. Diagnosis requires 4 of: 1. Avoids occupational activities that involve significant interpersonal contact for fear of criticism or rejection 2. Unwilling to get involved with people unless certain of being liked 3. Restrained in intimate relationships for fear of being shamed or ridiculed 4. Preoccupied with being rejected or criticized in social situations 5. Inhibited in new interpersonal situations due to fear of inadequacy 6. Views him or herself as inferior, socially inept or personally unappealing 7. Reluctant to engage in new activities for fear of embarrassment and fear of criticism.</td>
<td>Preoccupation with orderliness, perfectionism, and mental and interpersonal control. Is inflexible, closed-off, and inefficient. Diagnosis requires 4 of: 1. Preoccupation with details, rules, lists, order, organization, or schedules to the extent that the point of an activity is lost 2. Perfectionism interferes with task completion 3. Excessively devoted to work to the exclusion of leisure activities and friendships 4. Inflexible about morality/ethics/values 5. Unable to discard worthless objects of no sentimental value 6. Reluctant to delegate tasks to others 7. Misery spending style (money is hoarded for future disasters) 8. Rigid and stubborn</td>
</tr>
</tbody>
</table>

Dependent Personality Disorder (1.6-6.7%)

Pervasive and excessive need to be taken care of, excessive fear of separation, clinging and submissive behaviors. Difficulty making everyday decisions.

Diagnosis requires 5 of:
1. Difficulty making everyday decisions without advice and reassurance from others
2. Needs others to assume responsibility for most major areas of his/her life
3. Difficulty expressing disagreement
4. Difficulty initiating projects due to lack of self-confidence
5. Goes to excessive lengths to obtain support
6. Uncomfortable or helpless when alone because of fear of being unable to take care of him/herself
7. Urgently seeks another relationship as a source of care and support when a close relationship ends
8. Unrealistically preoccupied with fears of being left to take care of him/herself

Child Psychiatry

Developmental Concepts

- **temperament**: innate psycho-physiological and behavioral characteristics of a child (e.g. emotionality, activity, and sociability); spectrum from “difficult” to “slow-to-warm-up” to “easy temperament”
- **parental fit**: the congruence between parenting style (authoritative, authoritarian, permissive) and child’s temperament
- **attachment**: special relationship between child and primary caretaker(s); develops during first year, best predictor of a child’s attachment style is their parent’s attachment style
- **separation anxiety** (10-18 mo): separation from attachment figure results in distress
Table 11. Attachment Models

Mood Disorders

MAJOR DEPRESSIVE DISORDER

Epidemiology
- pre-pubertal 1-2% (no gender differences); post-pubertal 4-18% (F:M = 2:1)

Clinical Presentation
- see Adult Mood Disorders, PS6
- physical factors: insomnia (children), hypersomnia (adolescents), somatic complaints, substance abuse
- psychological factors: irritability, boredom, anhedonia, low self-esteem, deterioration in academic performance, social withdrawal, lack of motivation
- comorbid diagnoses of anxiety, ADHD, conduct disorder, and eating disorders

Treatment
- majority never seek treatment
- individual (CBT, IPT)/family therapy and education, modified school program
- SSRIs (strongest evidence for fluoxetine)
- ECT: only in adolescents

Prognosis
- prolonged episodes, up to 1-2 yr
- adolescent onset predicts chronic mood disorder; up to 2/3 will have another depressive episode within 5 yr
- complications
  - negative impact on family and peer relationships
  - school failure
  - significantly increased risk of suicide attempt (10%) or completion (however suicide risk low for pre-pubertal children)
  - substance abuse

BIPOLAR DISORDER

Clinical Presentation
- see Bipolar Disorder, PS9
- mixed presentation and psychotic symptoms (hallucinations and delusions) more common in adolescent population than adult population
- unipolar depression may be an early sign of adult bipolar disorder
  - ~30% of psychotic depressed adolescents receive a bipolar diagnosis within 2 yr of presentation
  - associated with rapid onset of depression, psychomotor retardation, mood-congruent psychosis, affective illness in family, pharmacologically-induced mania

Treatment
- 1st line: mood stabilizers and/or antipsychotics
- 2nd line: antidepressants, benzodiazepines (careful of disinhibiting effect)

Anxiety Disorders

- prevalence 2-15%; F:M = 2:1

Clinical Presentation
- school problems, recurrent physical symptoms (abdominal pain, headaches) especially in mornings, social and relationship problems, social withdrawal and isolation, family conflict, irritability and mood symptoms, alcohol and drug use in adolescent
Treatment
- family psychotherapy, predictive and supportive environment
- CBT: child and parental education, relaxation techniques (e.g. deep breathing), exposure/desensitization, recognizing and correcting anxious thoughts
- pharmacotherapy: SSRIs (e.g. fluoxetine), benzodiazepines (e.g. clonazepam – use with caution, may have disinhibiting effect)
  - fluvoxamine and sertraline also have good evidence, particularly for OCD

SEPARATION ANXIETY DISORDER

Epidemiology
- prevalence: 4% of children/adolescents
- average onset is 7.5 yr old; average age at presentation is 10 yr old
- common for mother to have an anxiety or depressive disorder

Differential Diagnosis
- simple or social phobia, depression, learning disorder, truancy, conduct disorder, school-related problems (e.g. bullying)

Clinical Presentation
- excessive and developmentally inappropriate anxiety on separation from primary caregiver with physical or emotional distress for at least 4 wk
- school refusal (75%)
- persistent worry, refusal to sleep, clinging, nightmares, somatic symptoms
- comorbid major depression common (2/3)
- worry about something happening to parent or themselves if separated

Prognosis
- if inadequately treated early on, may present later in a more severe form
- may develop into panic disorder with/without agoraphobia

SOCIAL PHOBIA (SOCIAL ANXIETY DISORDER)
- must distinguish between shy child and child with social anxiety
  - diagnosis only if anxiety interferes significantly with daily routine, social life, academic functioning, or if markedly distressed
- features: temper tantrums, freezing, clinging behavior, mutism, excessively timid, stays on periphery, refuses to be involved in group play
- must be capable of developing social relationships
- must occur in settings with peers, not just adults

SELECTIVE MUTISM
- consistent failure to speak in specific social situations in which there is an expectation for speaking despite speaking in other situations
- the disturbance interferes with educational or occupational achievement or with social communication

PANIC DISORDER
- diagnostic criteria same as adults (see Panic Disorder, PS10)
- genetic/parental modeling/identification hypothesized as cause
- often parent with panic or depressive disorder

GENERALIZED ANXIETY DISORDER
- diagnostic criteria same as adults (see Generalized Anxiety Disorder, PS12)
  - Note: only 1 item is required in children for Criteria C
- often redo tasks, show dissatisfaction with their work, and tend to be perfectionistic
- often require reassurance and support to take on new tasks

SPECIFIC PHOBIA
- common phobias in childhood include a fear of heights, small animals, doctors, dentists, darkness, loud noises, thunder and lightning
Neurodevelopmental Disorders

Autism Spectrum Disorder

• M:F = 3-4:1 (except for Rett’s with female predominance)

Diagnosis

• persistent deficits in social communication and interaction, manifested in three areas
  ▪ social-emotional reciprocity, ranging, for example, from abnormal social approach and
    failure of normal back-and-forth conversation, to reduced sharing of interests, emotions, or
    affect, to failure to initiate or respond to social interactions
  ▪ nonverbal communicative behaviors, ranging, for example, from poorly integrated verbal
    and nonverbal communication, to abnormalities in eye contact and body language or deficits
    in understanding and use of gestures, to a total lack of facial expressions and nonverbal
    communication
  ▪ developing, maintaining, and understanding relationships, ranging, for example, from
    difficulties adjusting behavior to suit various social contexts; to difficulties in sharing
    imaginative play or in making friends, to absence of interest in peers
• restricted, repetitive patterns of behavior, interests, or activities. Two or more of: stereotyped or
  repetitive motor movements, insistence on sameness, highly restricted fixated interests, hyper/
  hypo-reactivity to sensory input
• symptoms must be present in early developmental period
• symptoms cause clinically significant impairment in social, occupational, or other important
  areas of current functioning
• not better explained by intellectual disability or global developmental delay

• specifiers
  ▪ current severity: requiring very substantial support, requiring substantial support, requiring
    support
  ▪ with or without accompanying language impairment
  ▪ with or without accompanying intellectual impairment
  ▪ associated with known medical or genetic condition or environmental factors (i.e. Rett’s
    disorder)

Differential Diagnosis

• developmental disability, childhood schizophrenia, social phobia, OCD, communication
  disorder, non-verbal learning disorder, ADHD, abuse, hearing or visual impairment, seizure
  disorder, motor impairment

Management

• hearing test to rule out impairment
• psychological testing to assess intellectual functioning and learning
• chromosomal analysis to rule out abnormalities (e.g. Trisomy 21, Fragile X syndrome)
• rule out psychotic disorders, social problems, depression, anxiety, abuse

Treatment

• team-based: school, psychologist, occupational therapist, physiotherapist, speech and language
  therapy, audiology, pediatrics, psychiatry
• family education and support
• treat concomitant disorders such as tics, OCD, anxiety, depression, and seizure disorder
• behavior management, school programming
• pharmacotherapy: atypical antipsychotics (for aggression, agitation, self-mutilation, tics), SSRIs
  (for anxiety, depression), stimulants (for associated inattention and hyperactivity)

Prognosis

• variable, but improves with early intervention
• better if IQ >60 and able to communicate

Attention Deficit Hyperactivity Disorder

• prevalence: 5-12% of school-aged children; M:F = 4:1, although girls may be under-diagnosed
• girls tend to have inattentive/distractible symptoms; boys have impulsive/hyperactive symptoms

Etiology

• genetic: dopamine candidate genes, catecholamine/neuroanatomical hypothesis
• cognitive: developmental disability, inhibitory control and other errors of executive function
• arousal: alterations in the sensory system filters
Diagnosis
- differential: learning disorders, hearing/visual defects, thyroid, atopic conditions, congenital problems (fetal alcohol syndrome, Fragile X), lead poisoning, history of head injury, traumatic life events (abuse)
- diagnosis (3 subtypes)
  - **Combined Type**: 6 or more symptoms of inattention and 6 or more symptoms of hyperactivity-impulsivity
  - **Predominantly Inattentive Type**: 6 or more symptoms of inattention
  - **Predominantly Hyperactive-Impulsive Type**: 6 or more symptoms of hyperactivity-impulsivity
    - for older adolescents (>17 yr) or adults, 5 symptoms required
    - symptoms persist for >6 mo
    - onset before age 12
    - symptoms present in at least two settings (i.e. home, school, work)
    - interferes with academic, family, and social functioning
    - does not occur exclusively during the course of another psychiatric disorder

</tr>
</tbody>
</table>

**Features**
- average onset 3 yr old
- identification upon school entry
- rule out developmental delay, genetic syndromes, encephalopathies or toxins (alcohol, lead)
- risk of substance abuse, particularly cannabis and cocaine, depression, anxiety, academic failure, poor social skills, risk of comorbid CD and/or ODD, risk of adult ASPD
- associated with family history of ADHD, difficult temperamental characteristics

**Treatment**
- non-pharmacological: parent management, anger control strategies, positive reinforcement, social skills training, individual/family therapy, resource room, tutors, classroom intervention, exercise routines, extracurricular activities
- pharmacological
  - standard treatment
    - stimulants: methylphenidates (Ritalin®, Concerta® [long-acting]), Biphetin®
    - amphetamines: dextroamphetamine, mixed amphetamine salts (Adderall®), lisdexamfetamine (Vyvanse®)
  - SNRI: atomoxetine (Strattera®)
  - for comorbid symptoms: antidepressants, antipsychotics

**Prognosis**
- 65% continue into adulthood; secondary personality disorders and compensatory anxiety disorders are identifiable
- 70-80% continue into adolescence, but hyperactive symptoms usually abate
Disruptive, Impulse Control, and Conduct Disorder

Oppositional Defiant Disorder

- prevalence: 2-16%

**Diagnosis**
- pattern of negativistic/hostile and defiant behavior for ≥6 mo with ≥4 of
  - loses temper, argues with adults, defies adult rules, deliberately annoys, blames others,
  - touchy/easily annoyed, angry and resentful, spiteful or vindictive
  - behavior causes significant impairment in social, academic, or occupational functioning
- behaviors do not occur exclusively during the course of a psychotic or mood disorder
- criteria not met for conduct disorder (CD); if 18 yr or older, criteria not met for ASPD
- features that typically differentiate ODD from transient developmental stage: onset <8 yr,
  - chronic duration (>6 mo), frequent intrusive behavior
- impact of ODD: poor school performance, few friends, strained parent/child relationships
- may progress to CD

**Treatment**
- establish boundaries
- parent management training and psychoeducation
- individual/family therapy
- pharmacotherapy for comorbid disorders
- school/day care interventions to help with behavior management

Conduct Disorder

- prevalence: 1.5-3.4% (M:F = 4-12:1)

**Etiology**
- parental/familial factors: parental psychopathology (e.g. ASPD, substance abuse), child-rearing
  practices (e.g. child abuse, discipline), low socio-economic status (SES), family violence
- child factors: difficult temperament, ODD, learning problems, neurobiology

**Diagnosis**
- differential: ADHD, depression, head injury, substance abuse
- diagnosis: use multiple sources (Achenbach Child Behavioral Checklist, Teacher's Report Form)
  - pattern of behavior that violates rights of others and age appropriate social norms with ≥3
    criteria noted in past 12 mo and ≥1 in past 6 mo
    - aggression to people and animals (bullying, physical fights, use of weapons, forced sex)
    - destruction of property, firesetting with intent to damage
    - deceitfulness or theft (breaking and entering, car theft)
    - violation of rules (out all night before age 13, runaway ≥2 times or for long periods of
      time, often truant from school before age 13)
  - disturbance causes clinically significant impairment in social, academic, or occupational
    functioning
  - if individual is 18 yr or older, criteria not met for ASPD
  - diagnostic types
    - childhood onset: at least one criterion prior to age 10
      - poor prognosis: associated with ODD, aggressiveness, impulsiveness
    - adolescent onset: absence of any criteria until age 10
      - better prognosis; least aggressive, gang-related delinquency
    - mild, moderate, severe

**Treatment**
- early intervention necessary and more effective; long-term follow-up required
- parent management training, anger replacement training, CBT, family therapy, education/
  employment programs, social skills training, medications for aggressiveness or comorbid
  disorders
- pharmacotherapy is insufficient; mainly used for treatment of comorbid disorders

**Prognosis**
- poor prognostic indicators include early-age onset, high frequency and variety of behaviors,
  perseverance (i.e. in home, school, community), comorbid ADHD, early sexual activity,
  substance abuse
- 50% of CD children become adult ASPD
Pharmacotherapy

Antipsychotics

• “antipsychotics” and “neuroleptics” are terms used interchangeably
• indications: schizophrenia and other psychotic disorders, mood disorders with or without psychosis, violent behavior, autism, Tourette’s, dementia, OCD
• onset: immediate calming effect and decrease in agitation; thought disorder responds in 2-4 wk
• rational use
  ▪ no reason to combine antipsychotics
  ▪ choosing an antipsychotic
    † all antipsychotics are equally effective, except for clozapine (considered to be most effective in treatment-refractory psychosis)
    † atypical antipsychotics are as effective as typical or first generation antipsychotics but are thought to have better side effect profiles
    † choose a drug that the patient has responded to in the past or that was used successfully in a family member
  ▪ route: PO, short-acting or long-acting depot IM injections, sublingual
  ▪ duration: minimum 6 mo, usually for life

Long-Acting Preparations
• antipsychotics formulated in oil for IM injection
• received on an outpatient basis
• indications: individuals with schizophrenia or other chronic psychosis who relapse because of non-adherence
• dosing: start at low dosages, and then titrate every 2-4 wk to maximize safety and minimize side effects
• should be exposed to oral form prior to first injection
• side effects: risk of EPS, parkinsonism, increased risk of NMS

Table 13. Common Antipsychotic Agents

Effectiveness of Antipsychotic Drugs in Patients with Chronic Schizophrenia
NEJM 2005;353:1209-23
Study: Randomized, double-blind, active-control trial with median follow-up of 6 mo.
Patients: 1,432 patients with a diagnosis of schizophrenia (as per DSM-IV criteria) and able to take antipsychotic medications (as determined by study doctors). Mean age 41, 74% male, 26% female.
Intervention: 1-4 capsules daily of olanzapine (20.1 mg), quetiapine (543.4 mg), risperidone (3.9 mg), perphenazine (20.8 mg), or ziprasidone (112.8 mg), with dosage at the discretion of the study doctor. Mean modal doses in parentheses.
Main Outcome: Discontinuation of treatment for any cause
Results: Olanzapine group had statistically significant lower rate of discontinuation for any cause (64%) from all others (quetiapine – 82%, risperidone – 74%, perphenazine – 75%, ziprasidone – 79%). There were no significant differences in time until discontinuation due to intolerable side effects, however, olanzapine was associated with a significantly higher rate of metabolic side effects.

Typical vs. Atypical Antipsychotics

</tr>
</tbody>
</table>

**Neuroleptic Malignant Syndrome**
- psychiatric emergency
- due to massive dopamine blockade; increased incidence with high potency and depot neuroleptics
- risk factors
  - medication factors: sudden increase in dosage, starting a new drug
  - patient factors: medical illness, dehydration, exhaustion, poor nutrition, external heat load, male, young adults
- clinical presentation
  - mental status changes (usually occur first), fever, autonomic reactivity, rigidity
  - develops over 24-72 h
  - labs: increased creatine phosphokinase, leukocytosis, myoglobinuria
- treatment: discontinue drug, hydration, cooling blankets, dantrolene (hydrantoin derivative, used as a muscle relaxant), bromocriptine (DA agonist)
- mortality: 5%

**Extrapyramidal Symptoms**
- incidence related to increased dose and potency
- acute (early-onset; reversible) vs. tardive (late-onset; often irreversible)
Antidepressants

- **onset of effect**
  - relief of neurovegetative symptoms: 1-3 wk
  - relief of emotional/cognitive symptoms: 2-6 wk
- **may use mild stimulant (e.g. methylphenidate) for severe neurovegetative symptoms briefly and taper down as antidepressant effect increases**
- **taper TCAs slowly (over weeks-months) because they can cause withdrawal reactions**
- **tapering of any kind of antidepressant is usually required and based on the half-life of the medication and the patient's individual sensitivity**
- **it is important to be particularly vigilant over the first 2 wk of therapy as neurovegetative symptoms may start to resolve while emotional and cognitive symptoms may not (patients may be particularly at risk for suicidal behavior during this time)**
- **treatment of bipolar depression**
  - monotherapy with antidepressants is not advisable as a switch from depression to mania can occur
  - patients with bipolar disorder should only be treated with an antidepressant if it is combined with a mood stabilizer or antipsychotic
  - for patients taking mood stabilizers or antipsychotics, consider adding or switching to lithium or lamotrigine, or adding an SSRI or buproprion

### Antiparkinsonian Agents (Anticholinergic Agents)

- **types**
  - benztropine (Cogentin®) 2 mg PO, IM or IV OD (~1-6 mg)
  - amantadine (Symmetrel®) 100 mg PO bid (100-400 mg)
  - diphenhydramine (Benadryl®) 25-50 mg PO/IM qid
- **do not always prescribe with neuroleptics**
  - give antiparkinsonian agents only if at high risk for acute EPS or if acute EPS develops
- **do not give for tardive syndromes because they worsen the condition**

</tbody>
</table>

MAOI = monoamine oxidase inhibitors; NASSA = noradrenergic and specific serotonin antagonists; NDRI = norepinephrine and dopamine reuptake inhibitors; RIMA = reversible inhibition of MAO-A; SNRI = serotonin and norepinephrine reuptake inhibitors; SSRI = selective serotonin reuptake inhibitors; TCA = tricyclic antidepressants

Treatment Strategies for Refractory Depression

- **optimization**: ensuring adequate drug doses for the individual
- **augmentation**: the addition of a medication that is not considered an antidepressant to an antidepressant regimen (e.g. thyroid hormone, lithium, atypical antipsychotics)
- **combination**: the addition of another antidepressant to an existing treatment regimen (e.g. the addition of bupropion to an SSRI or SNRI)
- **substitute**: change in the primary antidepressant (within or outside a class)
- **note**: it is important to fully treat the symptoms of depression in order to decrease rates and severity of relapses

Psychopharmacology of SSRIs

<td>Tremors and seizures seen in acute overdose</td>
<td>Risk of fatal overdose when combined with citalopram or clomipramine</td>
<td>Mild symptoms with overdose</td>
<td></td>
</tr>
<tr>
<td><strong>Drug Interactions</strong></td>
<td>MAOI, Drugs that reduce seizure threshold: antipsychotics, systemic steroids, quinidine antibiotics, antimalarial drugs</td>
<td>MAOI, SSRI, TCA Opioids</td>
<td>MAOI, SSRI, SNRI, RIMA</td>
<td></td>
</tr>
</tbody>
</table>
Serotonin Syndrome
- thought to be due to over-stimulation of the serotonergic system
- can result from medication combinations such as SSRI+MAOI, SSRI+tryptophan, MAOI+meperidine, MAOI+tryptophan
- rare but potentially life-threatening adverse reaction to SSRIs, especially when switching from an SSRI to an MAOI
- symptoms include nausea, diarrhea, palpitations, chills, restlessness, confusion, and lethargy but can progress to myoclonus, hyperthermia, rigor and hypertonicity
- treatment: discontinue medication and administer emergency medical care as needed
- important to distinguish from NMS (see sidebar, PS38)

Discontinuation Syndrome
- caused by the abrupt cessation of an antidepressant
- observed most frequently with paroxetine, fluvoxamine, and venlafaxine
- symptoms usually begin within 1-3 d and include: anxiety, insomnia, irritability, mood lability, N/V, dizziness, headache, dystonia, tremor, chills, fatigue, lethargy, and myalgia
- treatment: symptoms may last between 1-3 wk, but can be relieved within 24 h by restarting antidepressant therapy at the same dose the patient was taking and initiating a slow taper over several weeks
- consider using a drug with a longer half-life such as fluoxetine

Mood Stabilizers

First-Line
Lithium or Valproic Acid (± antipsychotic)
- before initiating, get baseline: CBC, ECG (if patient >45 yr old or cardiovascular risk), urinalysis, BUN, Cr, electrolytes, TSH
- before initiating lithium: screen for pregnancy, thyroid disease, seizure disorder, neurological, renal, cardiovascular diseases
- may need acute coverage with benzodiazepines or antipsychotics
- use carbamazepine in non-responders and rapid cycling bipolar disorder
- can combine lithium and carbamazepine or valproic acid safely in lithium non-responders
- olanzapine may be used as a mood stabilizer, in conjunction with other mood stabilizers
- lithium and lamotrigine have established antidepressant efficacy

Lithium Toxicity
- clinical diagnosis as toxicity can occur at therapeutic levels
- common causes: overdose, sodium/fluid loss, concurrent medical illness
- clinical presentation
  - GI: severe nausea/vomiting and diarrhea
  - cerebellar: ataxia, slurred speech, lack of coordination
  - cerebral: drowsiness, myoclonus, choreiform or Parkinsonian movements, upper motor neuron signs, seizures, delirium, coma
- management
  - discontinue lithium for several doses and begin again at a lower dose when lithium level has fallen to a non-toxic range
  - serum lithium levels, BUN, electrolytes
  - saline infusion
  - hemodialysis if lithium >2 mmol/L, coma, shock, severe dehydration, failure to respond to treatment after 24 h, or deterioration

Second-Line/Adjuvant Mood Stabilizers
Lithium, lamotrigine, divalproex, carbamazepine

**Anxiolytics**

- anxiolytics mask or alleviate symptoms; they do not cure them
- **indications**
  - short-term treatment of transient forms of anxiety disorders, insomnia, alcohol withdrawal (especially delirium tremens), barbiturate withdrawal, organic brain syndrome (agitation in dementia), EPS and akathisia due to antipsychotics, seizure disorders, musculoskeletal disorders
- **relative contraindications**
  - major depression (except as an adjunct to other treatment), history of drug/alcohol abuse, pregnancy, breast feeding
- **mechanism of action**
  - benzodiazepines: potentiate binding of GABA to its receptors; results in decreased neuronal activity
  - buspirone: partial agonist of 5-HT1A receptors

**Benzodiazepines**

- should be used for limited periods (weeks-months) to avoid dependence
- all benzodiazepines are sedating; be wary in use for the elderly
- have similar efficacy, so choice depends on half-life, metabolites and route of administration, OD or bid
- taper slowly over weeks-months because they can cause withdrawal reactions
  - low dose withdrawal: tachycardia, HTN, panic, insomnia, anxiety, impaired memory and concentration, perceptual disturbances
  - high dose withdrawal: hyperpyrexia, seizures, psychosis, death
- avoid alcohol because of potentiation of CNS depression; caution with drinking and use of machinery
• side effects
  ▪ CNS: drowsiness, cognitive impairment, reduced motor coordination, memory impairment
  ▪ physical dependence, tolerance
• withdrawal
  ▪ symptoms: anxiety, insomnia, autonomic hyperactivity (less common)
  ▪ onset: 1-2 d (short-acting), 2-4 d (long-acting)
  ▪ duration: weeks-months
  ▪ complications with above 50 mg diazepam/d: seizures, delirium, arrhythmias, psychosis
  ▪ management: taper with long-acting benzodiazepine
  ▪ similar to but less severe than alcohol withdrawal, can be fatal
• overdose
  ▪ commonly used drug in overdose
  ▪ overdose is rarely fatal
  ▪ benzodiazepines are more dangerous and may cause death when combined with alcohol, other CNS depressants or TCAs

Benzodiazepine Antagonist – Flumazenil (Romazicon®)
• use for suspected benzodiazepine overdose
• specific antagonist at the benzodiazepine receptor site

Buspirone (Buspar®)
• primary use: GAD
• may be preferred over benzodiazepines because are non-sedating, no interaction with alcohol, does not alter seizure threshold, not prone to abuse
• onset of action: 2 wk
• side effects: dizziness, drowsiness, nausea, headache, nervousness, EPS

Electroconvulsive Therapy

• induction of a grand mal seizure using an electrical pulse through the brain while the patient is under general anesthesia with a muscle relaxant
• unilateral vs. bilateral electrode placement
• indications
  ▪ depression refractory to adequate pharmacological trial
  ▪ high suicide risk
  ▪ medical risk in addition to depression (dehydration, electrolytes, pregnancy)
  ▪ previous good response to ECT
  ▪ familial response to ECT
  ▪ elderly
  ▪ psychotic depression
  ▪ catatonic features

Geriatric Benzodiazepines
LOT
lorazepam
Oxazepam
Temazepam
Safe in liver disease because not metabolized by liver

Benozodiazepines used for Alcohol Withdrawal
• Diazepam 20 mg PO/IV q1h prn
• Lorazepam 2-5 mg PO/IV/SL for patients with liver disease, chronic lung disease, or elderly

Efficacy of ECT in Depression: A Meta-Analytic Review
J of ECT 2004; 20:13-20
Study: Meta-analysis of randomized and non-randomized control trials.
Patients: Individuals with unipolar and bipolar depression.
Main Outcomes: The Hamilton Depression Rating scale was used to determine response to treatment.
Results: ECT was found to be superior to simulated ECT, placebo, TCAs, MAOIs, and anti-depressants in general.
Summary: ECT is an efficacious treatment modality, particularly in severe and treatment-resistant depression.
- marked vegetative features
- acute schizophrenia unresponsive to medication
- mania unresponsive to medications

**side effects:** risk of anesthesia, memory loss (may be retrograde and/or anterograde, tends to resolve by 6 to 9 mo, permanent impairment controversial), headaches, myalgias

- evidence that unilateral ECT causes less memory loss than bilateral but may not be as effective

**contraindications:** increased intracranial pressure

Pulmonary Function Tests

- useful in differentiating the pattern of lung disease (obstructive vs. restrictive)
- assess lung volumes, flow rates, and diffusion capacity (see Figures 5A and 5B)
- note: normal values for FEV₁ are approximately ±20% of the predicted values (for age, sex, and height); ethnicity may affect predicted values

Arterial Blood Gases

- provides information on acid-base and oxygenation status
- see Nephrology, NP14

Approach to Acid-Base Status
1. Is the pH acidemic (pH < 7.35), alkalemic (pH > 7.45), or normal (pH 7.35-7.45)?
2. What is the primary disturbance?
   - metabolic: change in HCO₃⁻ and pH in same direction
   - respiratory: change in HCO₃⁻ and pH in opposite direction
3. Is there appropriate compensation? (see Table 8)
   - metabolic compensation occurs over 2-3 d reflecting altered renal HCO₃⁻ production and excretion
   - respiratory compensation through ventilatory control of PₐCO₂ occurs immediately
   - inadequate compensation may indicate a second acid-base disorder

Diffusion Capacity for Carbon Monoxide (DLCO)

DLCO decreases with:
- Decreased surface area (e.g. emphysema)
- Decreased hemoglobin
- Interstitial lung disease
- Pulmonary vascular disease

DLCO increases with:
- Asthma
- Pulmonary hemorrhage
- Polycythemia
- Increased pulmonary blood volume

OG = measured osmolarity – calculated osmolarity; for calculated osmolarity think “2 salts and a sticky BUN” (2Na + glucose + urea)

Note: Mixed acid-base disturbances can still have a “normal” pH

Anion Gap Metabolic Acidoses

MUDPILESCAT
- Methanol
- Uremia
- Diabetic ketoacidosis/starvation
- Phenformin/Paraldehyde
- Isoniazid, Isonicotinyl
- Cyanide, Carbon dioxide
- Alcoholic ketoacidosis
- Toluene, Theophylline

Acidosis ↔ Hyperkalemia
Alkalosis ↔ Hypokalemia

4. If there is metabolic acidosis, what is the anion gap and osmolar gap?
- Anion gap = [Na⁺]−([Cl⁻]+[HCO₃⁻]); normal ≤10-15 mEq/L
- Osmolar gap = measured osmolarity − calculated osmolarity = measured − (2[Na⁺] + glucose + urea); normal ≤10

5. If anion gap is increased, is the change in bicarbonate the same as the change in anion gap?
- If not, consider a mixed metabolic picture

- see Nephrology, NP15 for differential diagnosis of metabolic acidosis and alkalosis
Approach to Hypoxemia

**What is the PaO₂?** (normal 95-100 mmHg)
- PaO₂ < 95 mmHg

**What is the A-a gradient?**
(normal < 15 mmHg but increases with age)
- Increased A-a gradient (>15 mmHg) = lung disease
  - Decreased DL CO
- Lung normal A-a gradient (<15 mmHg) = normal lungs

PaO₂ improves
- V/Q mismatch
- Airway disease (asthma, COPD)
- ILD
- Alveolar disease
- Pulmonary vascular disease

PaO₂ does not improve
- Shunt
- Atelectasis
- Intraalveolar filling (e.g. pulmonary edema, pneumonia)
- Intracardiac shunt
- Vascular shunt within lungs

**Figure 8. Approach to hypoxemia**

**Figure 9. Pathophysiology of shunt**

Diseases of Airway Obstruction

**Pneumonia**
- see Infectious Diseases, ID8

**Asthma**
- see Family Medicine, FM15 and Pediatrics, P91

**Definition**
- chronic inflammatory disorder of the airways resulting in episodes of reversible bronchospasm causing airflow obstruction
- associated with reversible airflow limitation and airway hyper-responsiveness to endogenous or exogenous stimuli

**Epidemiology**
- common, 7-10% of adults, 10-15% of children
- most children with asthma significantly improve in adolescence
- often family history of atopy (asthma, allergic rhinitis, eczema)
- occupational asthma (organic allergies, isocyanates, animals, etc.)

**Red Flags**
- Central cyanosis is not detectable until SaO₂ is <85%. It is more easily detected in polycythemia and less readily detectable in anemia
- Severe tachypnea/tachycardia, respiratory muscle fatigue, diminished expiratory effort, cyanosis, silent chest, decreased LOC

**Asthma Action Plan**
- Is a written plan developed by patients and their physicians which includes signs and symptoms for patients to recognize their current level of respiratory distress (denoted as ‘green’, ‘yellow’, or ‘red/emergency’ zones) and the personalized treatment options for each zone
Pathophysiology
- airway obstruction → V/Q mismatch → hypoxemia → ↑ ventilation → ↓ P_{CO2} → ↑ pH and muscle fatigue → ↓ ventilation, ↑ P_{CO2}/↓ pH

Signs and Symptoms
- dyspnea, wheezing, chest tightness, cough (especially nocturnal), sputum
- symptoms can be paroxysmal or persistent
- signs of respiratory distress (see Figure 4)
- pulse paradoxus

<td></td>
</tr>
<tr>
<td>Exacerbations mild, infrequent</td>
<td></td>
</tr>
</tbody>
</table>

Adapted from Can Respir J 2012; 19:127-164

Investigations
- O₂ saturation
- ABGs (consider in acute exacerbation, along with peak flows, in Emergency Department)
  - decreased P_{O2} during attack (V/Q mismatch)
  - decreased P_{CO2} in mild asthma (hyperventilation)
  - normal or increased P_{CO2} is an ominous sign: patient is no longer able to hyperventilate (worsened airway obstruction or respiratory muscle fatigue)
- PFTs (do when stable)

<td>Children age 6+: PEF ↑ 20%</td>
</tr>
</tbody>
</table>

Adapted from Can Respir J 2012; 19:127-164

Treatment
- environment: avoid triggers
- patient education: features of the disease, goals of treatment, self-monitoring
- pharmacological
  - symptomatic relief in acute episodes: short-acting β₂-agonist, anticholinergic bronchodilators, oral steroids, addition of a long acting β₂-agonist
  - long-term prevention: inhaled/oral corticosteroids, anti-allergic agents, long-acting β₂-agonists, methylxanthine, LTRA, anti-IgE antibodies (e.g. Xolair®)

Emergency Management of Asthma
1. inhaled β₂-agonist first line (MDI route and spacer device recommended)
2. systemic steroids (PO or IV, if severe)
3. if severe, add anticholinergic therapy ± magnesium sulphate
4. rapid sequence intubation in life-threatening cases (plus 100% O₂, monitors, IV access)
5. SC/IV adrenaline if caused by anaphylaxis, IV salbutamol if unresponsive
6. corticosteroid therapy at discharge
Guidelines for Asthma Management

- see Family Medicine, FM15

Definition
- progressive, and irreversible condition of the lung characterized by chronic obstruction to airflow with many patients having periodic exacerbations, gas trapping, lung hyperinflation, and weight loss
- 2 subtypes (chronic bronchitis or emphysema); usually coexist to variable degrees
- gradual decrease in FEV1 over time with episodes of acute exacerbations

Table 13. Clinical and Pathologic Features of COPD*

<table>
<thead>

<td>Decreased elastic recoil of lung parenchyma causes decreased expiratory driving pressure, airway collapse, and air trapping</td>
</tr>
</tbody>
</table>

2 Types
1) Centriacinar (respiratory bronchioles predominantly affected)
   - Typical form seen in smokers, primarily affects upper lung zones
2) Panacinar (respiratory bronchioles, alveolar ducts, and alveolar sacs affected)
   - Accounts for about 1% of emphysema cases
   - α1-antitrypsin deficiency, primarily affects lower lobes

Risk Factors
- smoking is #1 risk factor
- others
  - environmental: air pollution, occupational exposure, exposure to wood smoke or other biomass fuel for cooking
  - treatable factors: α1-antitrypsin deficiency, bronchial hyperactivity
  - demographic factors: age, family history, male sex, history of childhood respiratory infections, low socioeconomic status

Pulmonary Embolism in Patients with Unexplained Exacerbation of COPD: Prevalence and Risk Factors
Ann Intern Med 2006;144:390-396
Study: Prospective cohort study of 211 patients with COPD (all current and former smokers) admitted to hospital for severe COPD exacerbation of unknown origin.

Measurements:
- All patients received spiral CT angiogram (CTA) and venous compression ultrasonography of both legs.

Results:
- 25% of patients met diagnostic criteria for PE (CTA or US).

Conclusions:
- Prevalence of PE in patients hospitalized for COPD exacerbation of unknown origin is 25%.
- Therefore, all patients presenting to hospital with COPD exacerbation without obvious cause require PE workup (leg dopplers or CTA – decision of which to use depends on pre-test probability of the patient).

Non-Invasive Positive Pressure Ventilation for Treatment of Respiratory Failure due to Exacerbations of COPD
Cochrane DB Syst Rev 2009;CD004104
Study: Cochrane Systematic Review. 14 RCTs.
Population: 758 adult patients with COPD and acute respiratory failure due to COPD exacerbation.

Intervention: Usual medical care (UMC) and Non-invasive positive ventilation (NPPV) vs. UMC alone.
Primary Outcome: Treatment failure, mortality, and tracheal intubation.
Results: The risks for all primary outcomes were reduced with NPPV use: treatment failure (RR 0.61); mortality (RR 0.52); and intubation use (RR 0.48). Length of hospital stay was a significant mean 3.24 d shorter, but no difference between ICU length of stay. There is a small and significant improvement in pH (weight mean difference (WMD)=0.40), aCO2 (WMD=0.40 kPa), and respiratory rate (WMD=3.08 bpm) within 1 h post-treatment with NPPV. Complications associated with treatment were reduced in the NPPV treatment arm (RR 0.38).
Conclusion: For patients in respiratory failure due to a COPD exacerbation, NPPV is effective in reducing treatment failure, mortality, and need for intubation when used as a first time treatment adjunct to UMC.

α1-Antitrypsin Deficiency
Inherited disorder of defective production of α1-antitrypsin, a protein produced by hepatocytes. Acts in the alveolar tissue by inhibiting the action of proteases from destroying alveolar tissue. When deficient, proteases can destroy lung alveoli resulting in emphysema

CO2 Retainers
On ABG, retainers have chronically elevated CO2 levels with a normal pH. Maintain QO2 Sat between BR-92% to prevent Haldane effect and decreased respiratory drive

*Note that both chronic bronchitis and emphysema can exist without obstruction. Only if obstruction is also present is it termed COPD

<td></td>
</tr>
<tr>
<td>Theophylline: weak bronchodilator; limited evidence to suggest combination with bronchodilator</td>
<td></td>
</tr>
<tr>
<td>• Side effects: nervous tremor, nausea/vomiting/diarrhea, tachycardia, arrhythmias, sleep changes</td>
<td></td>
</tr>
<tr>
<td>PDE4 inhibitor: roflumilast (Daliresp®) anti-inflammatory medication useful in COPD with chronic bronchitis, severe airflow obstruction, frequent exacerbations</td>
<td></td>
</tr>
</tbody>
</table>

Corticosteroids

ICS monotherapy is contraindicated and ICS should only be used with a LABA in combination in patients with a history of exacerbations COPD airways are usually inflamed but often not responsive to steroids, therefore avoid chronic systemic glucocorticoids (although oral steroids are very important when treating exacerbations)

Surgical

<table>
<thead>
<tr>
<th>Other</th>
<th>Patient education, eliminate respiratory irritants/allergens (occupational/environmental), exercise rehabilitation to improve physical endurance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lung volume reduction surgery (resection of emphysematous parts of lung, associated with higher mortality if FEV1 &lt;20%), lung transplant</td>
<td>Patient education, eliminate respiratory irritants/allergens (occupational/environmental), exercise rehabilitation to improve physical endurance</td>
</tr>
</tbody>
</table>

*Note: The distinction between “blue bloaters” and “pink puffers” is more of historical than practical interest as most COPD patients have elements of both.

Remember to step down therapy to lowest doses which control symptoms/signs of bronchoconstriction.

Complications of COPD

- Polycythemia 2° to hypoxemia
- Chronic hypoxemia
- Pulmonary HTN from vasoconstriction
- Cor pulmonale
- Pneumothorax due to rupture of emphysematous bullae

Influenza Vaccine for Patients with Chronic Obstructive Pulmonary Disease

Cochrane DB Syst Rev 2006;1:CD002733

Study: Cochrane Systematic Review. 10 RCTs included, 8 specifically in COPD patients.

Population: Six of the studies were done on COPD patients in particular, while the others were on elderly and high-risk individuals. Asthma patients were excluded.

Intervention: Live or inactivated virus vaccines vs. placebo.

Outcome: Exacerbation rates, hospitalizations, mortality, lung function and adverse effects.

Results: In patients with COPD, inactive-vaccine correlates with fewer exacerbations per vaccinated subject than placebo (weighted mean difference (WMD) -0.37, 95% CI -0.84 to -0.11). Inactivated vaccine resulted in fewer influenza-related infections than placebo (WMD 0.19, 95% CI 0.07-0.48). There was also an increased risk of local mild transient adverse reactions with the vaccine.

Conclusions: There appears to be a reduction in influenza related infections, as well as exacerbations in patients with COPD receiving the vaccine.

Systemic Corticosteroids for Acute Exacerbations of Chronic Obstructive Pulmonary Disease

Cochrane DB Syst Rev 2006;1:CD001288

Study: Cochrane Systematic Review. 10 RCTs contributed data for analysis.

Population: 1,051 total patients with COPD experiencing acute exacerbations.

Intervention: Oral or parenteral corticosteroids vs. placebo.

Outcome: Rate of treatment failure, length of hospitalization, FEV1.

Results: Patients receiving corticosteroids experienced fewer treatment failures than placebo (OR 0.50, 95% CI 0.36-0.69). The length of stay in hospital was shorter in patients receiving steroids (-1.22 d, 95% CI -2.26 to -0.18). There was also an improvement in FEV1 at 72 h (140 mL, 95% CI 90-190) and at end of treatment (up to 15 d) (89 mL, 95% CI 10-169). The risk of hypoglycemia was increased (OR 4.95, 95% CI 2.47-9.91).

Conclusions: There appears to be a reduction in rate of treatment failure, reduced length of hospitalization and improved FEV1 in patients receiving corticosteroid treatment for an acute exacerbation of COPD. However, there is also an increase in significant adverse effects. The ideal length of treatment remains controversial.
**Acute Exacerbations of COPD**

- **definition**
  - sustained (>24-48 h) worsening of dyspnea, cough, or sputum production leading to an increased use of medications
- **etiology**: viral URTI, bacteria, air pollution, CHF, PE, MI must be considered
- **management**
  - ABCs, consider assisted ventilation if decreasing LOC or poor ABGs
  - O$_2$ target 88-92% SaO$_2$ for CO$_2$ retainers
  - bronchodilators by MDI with spacer or nebulizer
  - SABA + anticholinergic, e.g. salbutamol and ipratropium bromide via nebulizers x 3 back-to-back q15min
  - systemic corticosteroids: IV solumedrol or oral prednisone
  - antibiotics if purulent sputum
  - simple exacerbation (no risk factors): amoxicillin, 2nd or 3rd generation cephalosporin, macrolide, or TMP/SMX
  - complicated exacerbation (one of: FEV$_1$ ≤50% predicted, ≥4 exacerbations per year, ischemic heart disease, home O$_2$ use, chronic oral steroid use): fluoroquinolone or β-lactam + β-lactamase inhibitor (amoxicillin/clavulanate)
  - post exacerbation: rehabilitation with general conditioning to improve exercise tolerance
- **ICU admission**
  - for life threatening exacerbations
  - ventilatory support
  - non-invasive: NPPV, BiPAP
  - conventional mechanical ventilation

**Prognosis in COPD**

- **prognostic factors**
  - level of dyspnea is the single best predictor
  - development of complications, e.g. hypoxemia or cor pulmonale
- **5 yr survival**
  - FEV$_1$ <1 L = 50%
  - FEV$_1$ <0.75 L = 33%
- **BODE index for risk of death in COPD**
  - greater score = higher probability the patient will die from COPD; score can also be used to predict hospitalization
  - 10 point index consisting of four factors
    - Body mass index (BMI): <21 (+1 point)
    - Obstruction (FEV$_1$): 50-64% (+1), 36-49% (+2), <35% (+3)
    - Dyspnea (MRC scale): walks slower than people of same age on level surface, stops occasionally (+1), stops at 100 yards or a few minutes on the level (+2), too breathless to leave house or breathless when dressing/undressing (+3)
    - Exercise capacity (6 minute walk distance): 250-349 m (+1), 150-249 m (+2), <149 m (+3)
Bronchiectasis

**Definition**
- irreversible dilatation of airways due to inflammatory destruction of airway walls resulting from persistently infected mucus
- usually affects medium sized airways
- *P. aeruginosa* is the most common pathogen; *S. aureus*, *H. influenzae*, and nontuberculous mycobacteria also common

**Table 16. Etiology and Pathophysiology of Bronchiectasis**

<table>

**Signs and Symptoms**
- chronic cough, purulent sputum (but 10-20% have dry cough), hemoptysis (can be massive), recurrent pneumonia, local crackles (inspiratory and expiratory), wheezes
- clubbing
- may be difficult to differentiate from chronic bronchitis

**Investigations**
- PFTs: often demonstrate obstructive pattern but may be normal
- CXR
  - nonspecific: increased markings, linear atelectasis, loss of volume in affected areas
  - specific: “tram tracking” – parallel narrow lines radiating from hilum, cystic spaces, honeycomb like structures
- high-resolution thoracic CT (diagnostic, gold standard)
  - 87-97% sensitivity, 93-100% specificity
  - “signet ring”: dilated bronchi with thickened walls where diameter bronchus > diameter of accompanying artery
  - sputum cultures (routine + AFB)
  - serum Ig levels
  - sweat chloride if cystic fibrosis suspected (upper zone predominant)

**Treatment**
- vaccination: influenza and Pneumovax®
- antibiotics (oral, IV, inhaled): routinely used for mild exacerbations, driven by sputum sensitivity; macrolides may be used chronically for an anti-inflammatory effect
- inhaled corticosteroids: decrease inflammation and improve FEV₁
- oral corticosteroids for acute, major exacerbations
- chest physiotherapy, breathing exercises, physical exercise
- pulmonary resection: in selected cases with focal bronchiectasis

Cystic Fibrosis

- see Pediatrics, P92

**Pathophysiology**
- chloride transport dysfunction: thick secretions from exocrine glands (lung, pancreas, skin, reproductive organs) and blockage of secretory ducts

**Clinical Features**
- results in severe lung disease, pancreatic insufficiency, diabetes, and azoospermia
- other manifestations: meconium ileus in infancy, distal ileal obstruction in adults, sinusitis, liver disease
- chronic lung infections
  - *S. aureus*: early
  - *P. aeruginosa*: most common
  - *B. cepacia*: worse prognosis but less common
  - *Aspergillus fumigatus*

**Investigations**
- sweat chloride test
  - increased concentrations of NaCl and K⁺ ([Cl⁻] >60 mEq/L is diagnostic in children)
  - heterozygotes have normal sweat tests (and no symptoms)
- PFTs
  - early: airflow limitation in small airways
  - late: severe airflow hyperinflation, gas trapping, decreased DLCO (very late)
• ABGs
  - hypoxemia, hypercapnia later in disease with eventual respiratory failure and cor pulmonale
• CXR
  - hyperinflation, increased pulmonary markings (especially upper lobes)

Treatment
• chest physiotherapy and postural drainage
• bronchodilators (salbutamol ± ipratropium bromide)
• inhaled mucolytic (reduces mucus viscosity), hypertonic saline DNase
• inhaled tobramycin
• antibiotics (e.g. ciprofloxacin)
• lung transplant
• pancreatic enzyme replacements

Prognosis
• depends on: infections (cepacia colonization), FEV₁, acute pulmonary exacerbations, lung transplant vs. non-lung transplant

### Interstitial Lung Disease

**Definition**
- a group of disorders which cause progressive scarring of lung tissue
- this scarring can eventually impair breathing and bloodstream oxygenation

**Pathophysiology**
- inflammatory and/or fibrosing process in the alveolar walls → distortion and destruction of normal alveoli and microvasculature
- typically associated with:
  - lung restriction (decrease in TLC and VC)
  - decreased lung compliance (increased or normal FEV₁/FVC)
  - impaired diffusion (decreased DLCO)
  - hypoxemia due to V/Q mismatch (usually without hypercapnia until end stage)
  - pulmonary HTN and cor pulmonale occur with advanced disease secondary to hypoxemia and blood vessel destruction

**Etiology**
- >100 known disorders can cause ILD
- majority due to unknown agents or cause

**Table 17. Interstitial Lung Diseases**

**Signs and Symptoms**
- SOB, especially on exertion
- nonproductive cough
- crackles (dry, fine, end-inspiratory)
- clubbing (especially in IPF and asbestosis)
- features of cor pulmonale
- note that signs and symptoms vary with underlying disease process
  - e.g. sarcoidosis is seldom associated with crackles and clubbing

**Investigations**
- CXR/high resolution CT (see Medical Imaging, MI7)
  - usually decreased lung volumes
  - reticular, nodular, or reticulonodular pattern (nodular <3 mm)
  - hilar/mediastinal adenopathy (especially in sarcoidosis)
- PFTs
  - restrictive pattern: decreased lung volumes and compliance
  - normal or increased FEV1/FVC (>70-80%), e.g. flow rates are often normal or high when corrected for absolute lung volume
  - DLco decreased due to V/Q mismatch less surface area for gas exchange ± pulmonary vascular disease
- ABGs
  - with progression of disease, hypoxemia and respiratory alkalosis may be present
- other
  - bronchoscopy, bronchoalveolar lavage, lung biopsy
  - ESR, ANA (lupus), RF (RA), serum-precipitating antibodies to inhaled organic antigens (hypersensitivity pneumonitis), c-ANCA (GPA)

**Unknown Etiologic Agents**

### IDIOPATHIC PULMONARY FIBROSIS

**Definition**
- also known as usual interstitial pneumonia or cryptogenic fibrosing alveolitis
- a progressive, irreversible condition characterized by fibrosis of lung parenchyma with no known cause
  - chest CT usually shows honeycomb lung, lung biopsy shows UIP (usual interstitial pneumonia) pattern
  - commonly presents over age 50, incidence rises with age; males > females
- DDx
  - other idiopathic interstitial pneumonia, especially NSIP, but also COP and:
    - desquamative interstitial pneumonitis (DIP)
    - lymphocytic interstitial pneumonitis (LIP): usually 2° to immune conditions such as HIV (mostly in children), Sjögren's

**Signs and Symptoms**
- commonly presents over age 50, incidence rises with age; males > females
- dyspnea on exertion, nonproductive cough, constitutional symptoms, late inspiratory fine crackles at lung bases, clubbing

**Investigations**
- labs (nonspecific, autoimmune serology usually negative)
- CXR: reticular or reticulonodular pattern with lower lung predominance; may appreciate honeycombing in advanced disease
- high resolution CT: lower zone peripheral reticular markings, traction bronchiectasis, honeycombing, ground glass not prominent in IPF
- biopsy: rarely for UIP as honeycombing makes radiologic diagnosis possible

**Treatment**
- O2
- N-acetylcysteine (anti-oxidant)
- lung transplantation for advanced disease
- mean survival of 3 to 5 yr after diagnosis

### SARCOIDOSIS

**Definition**
- idiopathic non-infectious granulomatous multi-system disease with lung involvement in 90%
- characterized pathologically by non-caseating granulomas
- numerous HLA antigens have been shown to play a role and familial sarcoidosis is now recognized
Epidemiology
- Typically affects young and middle-aged patients
- Higher incidence among African Americans and people at northern latitudes e.g. Scandinavia, Canada

Signs and Symptoms
- Asymptomatic, cough, dyspnea, fever, arthralgia, erythema nodosum, chest pain
- Chest exam often normal
- Common extrapulmonary manifestations
  - Cardiac (arrhythmias, sudden death)
  - Eye involvement (anterior or posterior uveitis)
  - Skin involvement (skin papules, erythema nodosum, lupus pernio)
  - Peripheral lymphadenopathy
  - Arthralgia
  - Hepatomegaly ± splenomegaly
- Less common extra-pulmonary manifestations involve bone, CNS, and kidney, cardiac (arrhythmias, sudden death)
- Two acute sarcoid syndromes
  - Lofgren’s syndrome: fever, erythema nodosum, bilateral hilar lymphadenopathy, arthralgias
  - Heerfordt-Waldenstrom syndrome: fever, parotid enlargement, anterior uveitis, facial nerve palsy

Investigations
- CBC (cytopenias from spleen or marrow involvement)
- Serum electrolytes, creatinine, liver enzymes, calcium (hypercalcemia/hypercalciuria due to vitamin D activation by granulomas)
- Hypergammaglobulinemia, occasionally RF positive
- Elevated serum ACE (non-specific and non-sensitive)
- CXR: predominantly nodular opacities especially in upper lung zones ± hilar adenopathy
- PFTs: normal, obstructive pattern, restrictive pattern with normal flow rates and decreased DLCO or mixed obstructive/restrictive
- ECG: to rule out conduction abnormalities
- Slit-lamp eye exam: to rule out uveitis

Diagnosis
- Biopsy
  - Transbronchial lung biopsy, transbronchial lymph node aspiration, endobronchial ultrasound guided surgical (EBUS) biopsy, or mediastinoscopic lymph node biopsy for granulomas
  - In ~75% of cases, transbronchial biopsy shows granulomas in the parenchyma even if the CXR is normal

Staging
- Radiographic, based on CXR
  - Stage 0: normal radiograph
  - Stage I: bilateral hilar lymphadenopathy ± right paratracheal lymphadenopathy
  - Stage II: bilateral hilar lymphadenopathy and diffuse interstitial disease
  - Stage III: interstitial disease only (reticulonodular pattern or nodular pattern)
  - Stage IV: pulmonary fibrosis (honeycombing)

Treatment
- 85% of stage I resolve spontaneously
- 50% of stage II resolve spontaneously
- Steroids for symptoms, declining lung function, hypercalcemia, or involvement of eye, CNS, kidney, or heart (not for abnormal CXR alone)
- Methotrexate or other immunosuppressives occasionally used

Prognosis
- Approximately 10% mortality secondary to progressive fibrosis of lung parenchyma

Known Etiologic Agents

**Hyperreactivity Pneumonitis**
- Also known as extrinsic allergic alveolitis
- Non-IgE mediated inflammation of lung parenchyma (acute, subacute, and chronic forms)
- Caused by sensitization to inhaled agents, usually organic dust
- Pathology: airway-centered, poorly formed granulomas and lymphocytic inflammation
- Exposure usually related to occupation or hobby
  - Farmer’s Lung (Thermophilic actinomyces)
  - Bird Breeder’s/Bird Fancier’s Lung (immune response to bird IgA)
  - Humidifier Lung (Aureobasidium pullulans)
  - Sauna Taker’s Lung (Aureobasidium spp.)

**Corticosteroids for Pulmonary Sarcoidosis**
- Cochrane DB Syst Rev 2005;CD001114
- Study: Meta-analysis of 13 RCTs involving 1,066 participants examining the use of steroids (oral or inhaled) in sarcoidosis.
- Results: Oral steroids demonstrated an improvement in CXR (RR 1.46, 95% CI 1.01-2.09). For inhaled corticosteroids, two studies showed no improvement in lung function and one study showed an improvement in diffusing capacity. No data on side-effects.
- Conclusions: Oral steroids improve CXR findings and global scores of CXR, symptoms, and spirometry over 3-24 mo, but do not improve lung function or modify disease course. Oral steroids may be of benefit for patients with Stage 2 and 3 disease.
Signs and Symptoms
• acute presentation: (4-6 h after exposure)
  - dyspnea, cough, fever, chills, malaise (lasting 18-24 h)
  - CXR: diffuse infiltrates
  - type III (immune complex) reaction
• subacute presentation: more insidious onset than acute presentation
• chronic presentation
  - insidious onset
  - dyspnea, cough, malaise, anorexia, weight loss
  - PFTs: progressively restrictive
  - CXR: predominantly upper lobe reticulonodular pattern
  - type IV (cell mediated, delayed hypersensitivity) reaction (see Rheumatology, R2)
• in both acute and chronic reactions, serum precipitins may be detectable (neither sensitive nor specific)

Treatment
• early diagnosis: avoidance of further exposure is critical as chronic changes are irreversible
• systemic corticosteroids can relieve symptoms and speed resolution

PNEUMOCONIOSES
• reaction to inhaled inorganic dusts 0.5-5 µm in size
  - no effective treatment, therefore key is exposure prevention through the use of protective equipment
  - smoking cessation, annual influenza and pneumococcal vaccination, rehabilitation, lung transplant for endstage disease

Table 18. Pneumoconioses

ILD ASSOCIATED WITH DRUGS OR TREATMENTS

Drug-Induced
• antineoplastic agents: bleomycin, mitomycin, busulfan, cyclophosphamide, methotrexate, chlorambucil, BCNU (carmustine)
• antibiotics: nitrofurantoin, penicillin, sulfonamide
• cardiovascular drugs: amiodarone, tocainide
• anti-inflammatory agents: methotrexate, penicillamine
• gold salts
• illicit drugs (heroin, methadone)
• rituximab, anti-TNF-α agents (infliximab, etanercept, adalimumab)

Radiation-Induced
• early pneumonitis: approximately 6 wk post-exposure
• late fibrosis: 6-12 mo post-exposure
• infiltrates conform to the shape of the radiation field
Pulmonary Vascular Disease

Pulmonary Hypertension

Definition

- mean pulmonary arterial pressure >25 mmHg at rest and >30 mmHg with exercise, or a systolic pulmonary artery pressure of >40 mmHg at rest
- in the past, pulmonary HTN was classified as primary or secondary pulmonary HTN, but this classification was modified to a more clinically useful, treatment based classification

</tbody>
</table>

Mechanisms of Pulmonary HTN (Simplified)

- hypoxic vasoconstriction
  - chronic hypoxia causes pulmonary vasoconstriction by a variety of actions on the pulmonary artery endothelium and smooth muscle cells, such as: down regulation of endothelial nitric oxide synthase and alteration of voltage gated potassium channels leading to vasoconstriction
  - causes: COPD, chronic alveolar hypoxia
- decreased area of pulmonary vascular bed
- leads to a rise in resting pulmonary arterial pressure
- causes: collagen vascular disease, HIV infection, drugs and toxins, thrombotic or embolic disease, inflammatory, pulmonary capillary hemangiomatosis, interstitial fibrosis, CF
- volume and pressure overload
- significant HTN only occurs with excessive volume overload, since pulmonary artery pressure will not rise in otherwise normal lung until pulmonary blood flow exceeds 2.5x the basal rate
- causes: congenital systemic to pulmonary shunts (e.g. VSD, ASD, PDA), portopulmonary HTN, left-sided heart conditions, pulmonary veno-occlusive disease, extrinsic compression of central pulmonary veins

Pulmonary arterial pressures are measured by pulmonary artery catheters (i.e. Swan-Ganz catheter) which are inserted into a large vein (often internal jugular). A balloon at the end of the catheter tip is inflated causing the catheter to advance through the right side of the heart and into the pulmonary artery. This allows for the measurement of RA, RV, PA, and pulmonary capillary wedge pressures as well as sampling of mixed venous blood. A thermistor near the end of the catheter also allows for assessment of cardiac output by thermodilution.
IDIOPATHIC PULMONARY ARTERIAL HTN (i.e. PRIMARY PULMONARY HTN)

Definition
- pulmonary HTN in the absence of a demonstrable cause
- exclude
  - left-sided cardiac valvular disease
  - myocardial disease
  - congenital heart disease
  - any clinically significant parenchymal lung disease
  - systemic connective-tissue disease
  - chronic thromboembolic disease

Epidemiology
- usually presents in young women (20-40 yr); mean age of diagnosis is 36 yr
- most cases are sporadic; familial predisposition in 10% of cases, some linked to mutations in BMPR2
- may be associated with the use of anorexic drugs (e.g. Aminorex®, Fenfluramine®), amphetamines and cocaine

Signs and Symptoms

Table 20. Signs and Symptoms of Pulmonary HTN

<td>If RV failure: right sided S3, increased JVP, positive HJR, peripheral edema, TR Reynaud’s phenomenon</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Investigations
- CXR: enlarged central pulmonary arteries, cardiac changes due to RV enlargement (filling of retrosternal air space)
- ECG
  - RVH/right-sided strain (see Cardiology and Cardiac Surgery, C7)
- 2-D echo doppler assessment of right ventricular systolic pressure
- cardiac catheterization: direct measurement of pulmonary artery pressures (necessary to confirm diagnosis)
- PFTs to assess for underlying lung disease: DLCO usually reduced; volumes and flows normal
- CT angiogram to assess lung parenchyma and possible PE
- V/Q scan ± pulmonary angiogram to rule out thromboembolic disease
- serology: ANA positive in 30% of patients with primary pulmonary HTN; other serologic markers can be used in the appropriate clinical setting

Treatment
- see Table 19

Prognosis
- 2-3 yr mean survival from time of diagnosis
- survival decreases to approximately 1 yr if severe pulmonary HTN or right-heart failure

Pulmonary Embolism

Definition
- lodging of a blood clot in the pulmonary arterial tree with subsequent increase in pulmonary vascular resistance, impaired V/Q matching, and possibly reduced pulmonary blood flow

Etiology and Pathophysiology
- one of the most common causes of preventable death in the hospital
- proximal leg thrombi (popliteal, femoral, or iliac veins) are the source of most clinically recognized pulmonary emboli
- thrombi often start in calf, but must propagate into proximal veins to create a sufficiently large thrombus for a clinically significant PE
- fewer than 30% of patients have clinical evidence of DVT (e.g. leg swelling, pain, or tenderness)
- always suspect PE if patient develops fever, sudden dyspnea, chest pain, or collapse 1-2 wk after surgery
### Risk Factors
- stasis
  - immobilization: paralysis, stroke, bed rest, prolonged sitting during travel, immobilization of an extremity after fracture
  - obesity, CHF
  - chronic venous insufficiency
- endothelial cell damage
- hypercoagulable states
  - underlying malignancy (particularly adenocarcinoma)
  - cancer treatment (chemotherapy, hormonal)
  - exogenous estrogen administration (OCP, HRT)
  - pregnancy, post-partum
  - prior history of DVT/PE, family history
  - nephrotic syndrome
  - coagulopathies: Factor V Leiden, Prothrombin 20210A variant, inherited deficiencies of antithrombin/protein C/protein S, antiphospholipid antibody, hyperhomocysteinemia, increased Factor VIII levels, and myeloproliferative disease
- increasing age

### Investigations (if highly suspicious, go straight to CT angiogram)
- see Emergency Medicine, Figure 13, ER34

### Table 21. Common Investigations for Pulmonary Embolism

<table>
<thead>
<tr>
<th>Investigation</th>
<th>Purpose/Utility</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pulmonary Angiogram (Gold Standard)</td>
<td>Filling defect indicative of embolus; negative angiogram excludes clinically relevant PE More invasive, and harder to perform than CT, therefore done infrequently</td>
</tr>
<tr>
<td>D-Dimer</td>
<td>Highly sensitive D-dimer result can exclude DVT/PE if pretest probability is already low Little value if pretest probability is high If D-dimer positive, will need further evaluation with compression U/S</td>
</tr>
<tr>
<td>CT Angiogram</td>
<td>Both sensitive and specific for PE Diagnosis and management uncertain for small filling defects CT may identify an alternative diagnosis if PE is not present CT scanning of the proximal leg and pelvic veins can be done at the same time and may be helpful</td>
</tr>
<tr>
<td>Venous Duplex U/S or Doppler</td>
<td>With leg symptoms Positive test rules in proximal DVT Negative test rules out proximal DVT Without leg symptoms Positive test rules in proximal DVT Negative test does not rule out a DVT: patient may have non-occlusive or calf DVT</td>
</tr>
<tr>
<td>ECG</td>
<td>Findings not sensitive or specific Sinus tachycardia most common; may see non-specific ST segment and T wave changes RV strain, RAD, RBBB, S1-Q3-T3 with massive embolization</td>
</tr>
<tr>
<td>CXR</td>
<td>Frequently normal; no specific features Atelectasis (subsegmental), elevation of a hemidiaphragm Pleural effusion: usually small Hampton’s hump: cone-shaped area of peripheral opacification representing infarction Westermark’s sign: dilated proximal pulmonary artery with distal oligemia/decreased vascular markings (difficult to assess without prior films) Dilatation of proximal PA: rare</td>
</tr>
<tr>
<td>V/Q Scan</td>
<td>Very sensitive but low specificity Order scan if CXR normal, no COPD Contraindication to CT (contrast allergy, renal dysfunction, pregnancy) Avoid V/Q scan if CXR abnormal or COPD Inpatient Suspect massive PE Results Normal: excludes the diagnosis of PE High probability: most likely means PE present, unless pre-test probability is low 60% of V/Q scans are nondiagnostic</td>
</tr>
<tr>
<td>Echocardiogram</td>
<td>Useful to assess massive or chronic PE Not routinely done</td>
</tr>
<tr>
<td>ABG</td>
<td>No diagnostic use in PE (insensitive and nonspecific) May show respiratory alkalosis (due to hyperventilation)</td>
</tr>
</tbody>
</table>
Treatment
- admit for observation (patients with DVT only are often sent home on LMWH)
- oxygen: supplemental O₂ if hypoxic or short of breath
- pain relief: analgesics if chest pain – narcotics or acetaminophen
- acute anticoagulation: therapeutic-dose SC LMWH or IV heparin – start ASAP
  - anticoagulation stops clot propagation, prevents new clots and allows endogenous fibrinolytic system to dissolve existing thromboemboli over months
  - get baseline CBC, INR, aPTT ± renal function ± liver function
  - for SC LMWH: dalteparin 200 U/kg once daily or enoxaparin 1 mg/kg bid – no lab monitoring – avoid or reduce dose in renal dysfunction
  - for IV heparin: bolus of 75 U/kg (usually 5,000 U) followed by infusion starting at 20 U/kg/h – aim for aPTT 2-3x control
- long-term anticoagulation
  - warfarin: start the same day as LMWH/heparin – overlap warfarin with LMWH/heparin for at least 5 d and until INR in target range of 2-3 for at least 2 d
  - LMW instead of warfarin for pregnancy, active cancer, or high bleeding risk patients
  - dabigatran has been shown to have lower bleeding risk than warfarin
- IV thrombolytic therapy
  - if patient has massive PE (hypotension or clinical right heart failure) and no contraindications
  - hastens resolution of PE but may not improve survival or long-term outcome and doubles risk of major bleeding
- interventional thrombolytic therapy
  - massive PE is preferentially treated with catheter-directed thrombolysis by an interventional radiologist
  - works better than IV thrombolytic therapy and fewer contraindications
- IVC filter: only if recent proximal DVT + absolute contraindication to anticoagulation
- duration of long-term anticoagulation: individualized, however generally:
  - if reversible cause for PE (surgery, injury, pregnancy, etc.): 3-6 mo
  - if PE unprovoked: 6 mo to indefinite
  - if ongoing major risk factor (active cancer, antiphospholipid antibody, etc.): indefinite

Thromboprophylaxis
- mandatory for most hospital patients: reduces DVT, PE, all-cause mortality, cost-effective
- start ASAP
- continue at least until discharge or recommend extending for 35 d post-operatively, if major orthopedic surgery

Workup for Idiopathic VTE
Thrombophilia Workup: recurrent or idiopathic DVT/PE, age <50, FHx, unusual location, massive
Malignancy Workup: 12% of patients with idiopathic VTE will have a malignancy

Extended Use of Dabigatran, Warfarin or Placebo in Venous Thrombembolism
NEJM 2013;368:709-719
Study: Two double blind, RCTs; one comparing against placebo, the other against active treatment
Population: 4,199 patients (2,656 in active-control study, 1,343 in placebo-control study) with VTE who had completed at least 3 mo of therapy.
Intervention: In the active-control study, patients randomized to either 150 mg dabigatran or warfarin (INR 2.0-3.0). Patients in the placebo-control study received either 150 mg dabigatran or placebo.
Outcome: Recurrence of VTE, risk of major or clinically relevant bleed.
Results: In the active-control study, there was a hazard ratio (HR) of 1.44 (95% CI 0.79-2.64) for non-inferiority of recurrent VTE with dabigatran vs. warfarin. HR of major or clinically relevant bleed was 0.54 (95% CI 0.41-0.71). In the placebo-control study, the HR of VTE with dabigatran vs. placebo was 2.08 (95% CI 0.92-4.64). HR of major or clinically relevant bleed was 2.92 (95% CI 1.52-5.60).
Conclusions: Dabigatran appears to be non-inferior to warfarin in the prevention of VTE recurrence. Dabigatran is associated with a lower risk of major or clinically relevant bleed than warfarin, but greater than placebo.

Excluding Pulmonary Embolism at Bedside without Diagnostic Imaging
Study: Multicenter, prospective cohort study.
Patients: 930 patients with suspected PE at emergency departments at 4 tertiary care hospitals in Canada.
Intervention: A Wells score was used to determine patient’s pretest probability (PTP) of PE along with a D-dimer test. Patients with low PTP and a negative D-dimer test had no further testing and the diagnosis of PE was excluded. All other patients had V/Q scanning, and if non-diagnostic, had bilateral deep venous ultrasonography. Further serial ultrasonography and angiography were done depending on the patients PTP and lung scanning results.
Main Outcomes: Diagnosis of PE and the development of thromboembolic events at 3 mo follow-up.
Results: One of 793 patients in whom PE was initially ruled out developed a thromboembolic event during follow-up (0.1% CI 0.0%-0.3%). One of the 437 patients with negative D-dimers and low clinical PTP developed PE during follow up (NPV 99.5%, CI 99.1-100%).
Conclusions: Managing patients with suspected pulmonary embolism on the basis of PTP and D-dimer results is safe and decreases the need for diagnostic imaging.

## Pulmonary Edema
- see Cardiology and Cardiac Surgery, C35

## Diseases of the Mediastinum and Pleura

### Mediastinal Masses

#### Definition
- mediastinum: bound by the thoracic inlet, diaphragm, sternum, vertebral bodies, and the pleura
- can be broken down into 3 compartments: anterior, middle, and posterior

#### Etiology and Pathophysiology
- diagnosis is made by location and patient's age
- anterior compartment: more likely to be malignant
  - "Four Ts" (see sidebar), lymphoma, lipoma, pericardial cyst
- middle compartment
  - pericardial cyst, bronchogenic cyst/tumor, lymphoma, lymph node enlargement, aortic aneurysm
- posterior compartment
  - neurogenic tumors, meningocoele, enteric cysts, lymphoma, diaphragmatic hernias, esophageal tumor, aortic aneurysm

#### Signs and Symptoms
- 50% asymptomatic (mainly benign); when symptomatic, 50% are malignant
- chest pain, cough, dyspnea, recurrent respiratory infections
- hoarseness, dysphagia, Horner's syndrome, facial/upper extremity edema (SVC compression)
- paraneoplastic syndromes (e.g. myasthenia gravis [thymomas])

#### Investigations
- CXR (compare to previous)
- CT with contrast (anatomic location, density, relation to mediastinal vascular structures)
- MRI: specifically indicated in the evaluation of neurogenic tumors
- U/S (best for assessment of structures in close proximity to the heart and pericardium)
- radionuclide scanning: 131I (for thyroid), gallium (for lymphoma)
- biochemical studies: thyroid function, serum calcium, phosphate, PTH, AFP, β-hCG
- biopsy (mediastinoscopy, percutaneous needle aspiration)
Management
- excision if symptomatic enlarging benign masses or concerns of malignancy
- resect bronchogenic cysts and localized neurogenic tumors via minimally invasive video assisted procedures
- exploration via sternotomy or thoracotomy
- diagnostic biopsy rather than major operation if mass is likely to be a lymphoma, germ cell tumor, or unresectable invasive malignancy
- ± post-operative radiotherapy/chemotherapy if malignant

Mediastinitis
- commonest causes: post-operative complications of cardiovascular or thoracic surgical procedures

Acute
- etiology
  - complication of endoscopy (e.g. esophageal perforation providing entry point for infection)
  - esophageal or cardiac surgery
  - tumor necrosis
- signs and symptoms
  - fever, substernal pain
  - pneumomediastinum, mediastinal compression
  - Hamman’s sign (auscultatory “crunch” during cardiac systole)
- treatment
  - antibiotics, drainage, ± surgical closure of perforation

Chronic
- usually granulomatous process or fibrosis related to previous infection (e.g. histoplasmosis, TB, sarcoidosis, syphilis)

Pleural Effusions
Definition
- excess amount of fluid in the pleural space

Etiology
- disruption of normal equilibrium between pleural fluid formation/entry and pleural fluid absorption/exit
- pleural effusions are classified as transudative or exudative
  - distinguish clinically using Light’s Criteria, which has a sensitivity of 98% and specificity of 83% for identifying exudative pleural effusions

Table 24. Laboratory Values in Transudative and Exudative Pleural Effusion

<td>&gt;0.45 upper limit of N serum LDH</td>
</tr>
</tbody>
</table>

Transudative Pleural Effusions
- pathophysiology: alteration of systemic factors that affect the formation and absorption of pleural fluid (e.g. increased capillary hydrostatic pressure, decreased plasma oncotic pressure)
- etiology
  - CHF: usually right-sided or bilateral cirrhosis
  - nephrotic syndrome, protein losing enteropathy, cirrhosis
  - pulmonary embolism (may cause transudative but more often causes exudative effusion)
  - peritoneal dialysis, hypothyroidism, CF, urinothorax

Exudative Pleural Effusions
- pathophysiology: increased permeability of pleural capillaries or lymphatic dysfunction
- etiology (see Table 25)
### Table 25. Exudative Pleural Effusion Etiologies

<tr>
<td></td>
<td>Pneumotorax (spontaneous, traumatic, tension)</td>
</tr>
</tbody>
</table>

### Signs and Symptoms
- often asymptomatic
- dyspnea: varies with size of effusion and underlying lung function
- pleuritic chest pain
- inspection: trachea deviates away from effusion, ipsilateral decreased expansion
- percussion: decreased tactile fremitus, dullness
- auscultation: decreased breath sounds, bronchial breathing and egophony at upper level, pleural friction rub

### Investigations
- **CXR**
  - must have >200 mL of pleural fluid for visualization on PA film
  - lateral: >50 mL leads to blunting of posterior costophrenic angle
  - PA: blunting of lateral costophrenic angle
  - dense opacification of lung fields with concave meniscus
  - decubitus: fluid will shift unless it is loculated
  - supine: fluid will appear as general haziness
- thoracentesis: indicated if pleural effusion is a new finding; be sure to send off blood work (LDH, glucose, protein) at the same time for comparison
- risk of re-expansion pulmonary edema if >1.5 L of fluid is removed
- inspect for color, character, and odor of fluid
- analyze fluid
- pleural biopsy: indicated if suspect TB, mesothelioma, or other malignancy (and if cytology negative)
- ± U/S: detects small effusions and can guide thoracentesis
- treatment depends on cause, ± drainage if symptomatic
- CT can be helpful in differentiating parenchymal from pleural abnormalities

</tbody>
</table>
Treatment
- thoracentesis
- treat underlying cause
- consider indwelling pleural catheter or pleurodesis in refractory effusions

**Complicated Parapneumonic Effusion**
- persistent bacteria in the pleural space but fluid is non-purulent
- neutrophils, pleural fluid acidosis (pH < 7.00), and high LDH
- often no bacteria grown since rapidly cleared from pleural space
- fibrin layer leading to loculation of pleural fluid
- treatment: antibiotics and drainage, treat as an empyema

**Empyema**

**Definition**
- pus in pleural space or an effusion with organisms seen on a Gram stain or culture (e.g. pleural fluid is grossly purulent)
- positive culture is not required for diagnosis

**Etiology**
- contiguous spread from lung infection (most commonly anaerobes) or infection through chest wall (e.g. trauma, surgery)

**Signs and Symptoms**
- fever, pleuritic chest pain

**Investigations**
- CT chest
- thoracentesis
- PMNs (lymphocytes in TB) ± visible organisms on Gram stain

**Treatment**
- antibiotic therapy for at least 4-6 wk (rarely effective alone)
- complete pleural drainage with chest tube
- if loculated, more difficult to drain – may require surgical drainage with video-assisted thorascopic surgery (VATS)

**Atelectasis**

- see General Surgery, GS10

**Pneumothorax**

**Definition**
- presence of air in the pleural space

**Pathophysiology**
- entry of air into pleural space raises intrapleural pressure causing partial lung deflation

**Etiology**
- traumatic: penetrating or non-penetrating chest injuries
- iatrogenic (central venous catheter, thoracentesis, mechanical ventilation with barotrauma)
- spontaneous (no history of trauma)
  - primary (no underlying lung disease)
    - spontaneous rupture of apical subpleural bleb of lung into pleural space
    - predominantly tall, healthy, young males
  - secondary (underlying lung disease)
    - rupture of subpleural bleb which migrates along bronchioalveolar sheath to the mediastinum then to the intrapleural space
    - necrosis of lung tissue adjacent to pleural surface (e.g. pneumonia, abscess, PCP, lung CA, emphysema)

**Signs and Symptoms**
- can be asymptomatic
- acute-onset pleuritic chest pain, dyspnea
- tachypnea, tachycardia

**Need to Rule Out Life-Threatening Tension Pneumothorax**
- Severe respiratory distress
- Tracheal deviation to contralateral side
- Distended neck veins (JVP)
- Hypotension

Do not perform CXR
Needs immediate treatment
See Emergency Medicine, ER11
• tracheal deviation (contralateral deviation in tension pneumothorax)
• ipsilateral diminished chest expansion
• decreased tactile/vocal fremitus
• hyperresonance
• ipsilateral diminished breath sounds

Investigations
• CXR
  ▪ small: separation of visceral and parietal pleura seen as fine crescentic line parallel to chest wall at apex
  ▪ large: increased density and decreased volume of lung on side of pneumothorax
  ▪ see Medical Imaging, MI8

Treatment
• small pneumothoraces (<20% with no signs of respiratory/circulatory collapse) resolve spontaneously; breathing 100% oxygen accelerates resorption of air
• small intercostal tube with Heimlich valve for most spontaneous pneumothoraces
• large pneumothoraces or those complicating underlying lung disease require placement of a chest tube connected to underwater seal ± suction
• for repeated episodes: pleurodesis with sclerosing agent or apical bullectomy and abrasion
• treat underlying cause (e.g. antibiotic for PCP)

Asbestos-Related Pleural Disease and Mesothelioma

Etiology and Pathophysiology
• benign manifestations of asbestos exposure
  ▪ "benign asbestos pleural effusion"
  ▪ exudative effusion, typically ~10 yr after exposure, resolves
  ▪ pleural plaques, usually calcified
  ▪ marker of exposure; usually an asymptomatic radiologic finding
• mesothelioma
  ▪ primary malignancy of the pleura
  ▪ decades after asbestos exposure (even with limited exposure)
  ▪ smoking not a risk factor, but asbestos and smoking synergistically increase risk of lung cancer

Signs and Symptoms
• persistent chest pain, dyspnea, cough, bloody pleural effusion, weight loss

Investigations
• biopsy (pleuroscopic or open)
• needle biopsy may seed needle tract with tumor

Treatment
• resection (extrapleural pneumonectomy) requires careful patient selection; rarely successful (average survival <1 yr)

Respiratory Failure

Definition
• failure of respiratory system to maintain normal blood gases
• hypoxemic (P_{O2} <60 mmHg)
• hypercapnic (P_{CO2} >50 mmHg)
• acute vs. chronic (compensatory mechanisms activated)

Signs and Symptoms
• signs of underlying disease
• hypoxemia: restlessness, confusion, cyanosis, coma, cor pulmonale
• hypercapnia: headache, dyspnea, drowsiness, asterixis, warm periphery, plethora, increased ICP (secondary to vasodilatation)

Investigations
• serial ABGs
• CXR and/or CT, bronchoscopy to characterize underlying cause if unclear
**Hypoxemic Respiratory Failure**

**Definition**
- \( P_aO_2 \) decreased, \( P_aCO_2 \) normal or decreased

**Treatment**
- reverse the underlying pathology
- oxygen therapy: maintain oxygenation (if shunt present, supplemental \( O_2 \) is less effective; see Anesthesia, A9, for oxygen delivery systems)
- ventilation, BiPAP, and PEEP/CPAP (see Anesthesia, A10): positive pressure can recruit alveoli and redistribute lung fluid
- improve cardiac output: ± hemodynamic support (fluids, vasopressors, inotropes), reduction of \( O_2 \) requirements

<table>

</tbody>
</table>

Reprinted with permission from Dr. Ian Fraser

**Hypercapnic Respiratory Failure**

- \( P_aCO_2 \) increased, \( P_aO_2 \) decreased

**Pathophysiology**
- increased \( CO_2 \) production: fever, sepsis, seizure, acidosis, carbohydrate load
- alveolar hypoventilation: COPD, asthma, CF; chest wall disorder, dead space ventilation (rapid shallow breathing)
  - inefficient gas exchange results in inadequate \( CO_2 \) removal in spite of normal or increased minute volume
- hypoventilation
  - central: brainstem stroke, hypothyroidism, severe metabolic alkalosis, drugs (opiates, benzodiazepines)
  - neuromuscular: myasthenia gravis, Guillain-Barré, phrenic nerve injury, muscular dystrophy, polymyositis, kyphoscoliosis
  - muscle fatigue

**Treatment**
- reverse the underlying pathology
- if \( P_aCO_2 >50 \, mmHg \) and \( pH \) is acidemic consider noninvasive or mechanical ventilation
- correct exacerbating factors
  - NTT/ETT suction: clearance of secretions
  - bronchodilators: reduction of airway resistance
  - antibiotics: treatment of infections
- maintain oxygenation (see above)
- diet: increased carbohydrate can increase \( P_aCO_2 \) in those with mechanical or limited alveolar ventilation; high lipids decrease \( P_aCO_2 \)

**Dead Space**
- Ventilation without perfusion
- The opposite of shunt

**Causes of Hypercapnia**
- High Inspired \( CO_2 \)
- Low Total Ventilation
- High Deadspace Ventilation
- High \( CO_2 \) Production

In chronic hypercapnia, supplemental \( O_2 \) may decrease the hypoxic drive to breathe, but do not deny oxygen if the patient is hypoxic

In COPD patients with chronic hypercapnia (“CO2 retainers”), provide supplemental oxygen to achieve target \( SaO_2 \) from 88-92%
Acute Respiratory Distress Syndrome

- clinical syndrome characterized by severe respiratory distress, hypoxemia, and noncardiogenic pulmonary edema
- The Berlin Criteria (JAMA 2012; 307:2526-2533) for ARDS
  - acute onset
    - within 7 d of a defined event, such as sepsis, pneumonia, or patient noticing worsening of respiratory symptoms
    - usually occurs within 72 h of presumed trigger
    - bilateral opacities consistent with pulmonary edema on either CT or CXR
    - not fully explained by cardiac failure/fluid overload, but patient may have concurrent heart failure
    - an objective assessment (e.g. echocardiogram) should be performed if no clear risk factors

Etiology
- direct lung injury
  - airway: aspiration (gastric contents, drowning), pneumonia, inhalation injury (oxygen toxicity, nitrogen dioxide, smoke)
  - circulation: embolism (fat, amniotic fluid), reperfusion injury
- indirect lung injury
  - circulation: sepsis, shock, trauma, blood transfusion, pancreatitis
  - neurogenic: head trauma, intracranial hemorrhage, drug overdose (narcotics, sedatives, TCAs)

Pathophysiology
- disruption of alveolar capillary membranes → leaky capillaries → interstitial and alveolar pulmonary edema → reduced compliance, V/Q mismatch, shunt, hypoxemia, pulmonary HTN

Clinical Course
A. Exudative Phase
- first 7 d of illness after exposure to ARDS precipitant
- alveolar capillary endothelial cells and type I pneumocytes are injured, resulting in loss of normally tight alveolar barrier
- patients develop dyspnea, tachypnea, increased work of breathing
  - these result in respiratory fatigue and eventually respiratory failure (see Hypoxemic Respiratory Failure, R26)

B. Fibroproliferative Phase
- after day 7
- may still experience dyspnea, tachypnea, fatigue, and hypoxemia
- most patients clinically improve and are able to wean off mechanical ventilation
- some patients develop fibrotic lung changes that may require long-term support on supplemental oxygen or even mechanical ventilation
- if fibrosis present, associated with increased mortality

Treatment
- based on ARDS network (see Landmark Respirology Trials, R36)
- treat underlying disorder (e.g. antibiotics if infection present)
- mechanical ventilation using low tidal volumes (<6 mL/kg) to prevent barotrauma
  - use optimal amount of PEEP (positive end-expiratory pressure) to keep airways open and allow the use of lower FIO2
  - may consider using prone ventilation, and/or inhaled nitric oxide, high frequency oscillator or ECMO (extracorporeal membrane oxygenation) if conventional treatment is failing
- fluids and inotropic therapy (e.g. dopamine, vasopressin) if cardiac output inadequate
- pulmonary-arterial catheter now seldom used for monitoring hemodynamics
- mortality: 30-40%, usually due to non-pulmonary complications
- sequelae of ARDS include residual pulmonary impairment, severe debilitation, polynuropathy and psychologic difficulties, which gradually improve over time
- most survivors eventually regain near-normal lung function, often with mildly reduced diffusion capacity

Lung Cancer

Classification
- Lung tumors can be classified as primary or secondary, benign or malignant, endobronchial or parenchymal.
- Bronchogenic carcinoma (epithelial lung tumors) are the most common type of primary lung tumor (other types make up less than 1%)
  - Small cell lung cancer (SCLC)
  - Non-small-cell lung cancer (NSCLC)
- Squamous cell carcinoma: arise from the proximal respiratory epithelium
- Adenocarcinoma: incidence is increasing; most common subtype in nonsmokers
  - Bronchoalveolar carcinoma: grows along the alveolar wall in the periphery; may arise at sites of previous lung scarring
- Large cell undifferentiated cancer: diagnosis of exclusion
- Benign epithelial lung tumors can be classified as papillomas or adenomas

<table>
<thead>
<tr>
<th>Table 28. Characteristics of Bronchogenic Cancer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cell Type</td>

</tr>
<tr>
<td>Adenocarcinoma</td>
</tr>
<tr>
<td>Squamous Cell Carcinoma (SCC)</td>
</tr>
<tr>
<td>SCLC</td>
</tr>
<tr>
<td>Large Cell Carcinoma</td>
</tr>
</tbody>
</table>

Risk Factors
- Cigarette smoking: the relative risk of developing lung cancer is 10-30 times higher for smokers than for nonsmokers.
- Other risk factors include cigar smoking, pipe smoking, second-hand smoke, asbestos without smoking, environmental tobacco smoke, radon gas, ionizing radiation, genetics.

Signs and Symptoms
- May be due to primary lesion, metastasis, or paraneoplastic syndrome.
- Primary lesion
  - Cough (75%): beware of chronic cough that changes in character
  - Dyspnea (60%)
  - Chest pain (45%)
  - Hemoptysis (35%)
  - Other pain (25%)
  - Clubbing (21%)
- Constitutional symptoms: anorexia, weight loss, fever, anemia
- Metastasis
  - Lung, hilum, mediastinum, pleura: pleural effusion, atelectasis, wheezing
  - Pericardium: pericarditis, pericardial tamponade
  - Esophageal compression: dysphagia
  - Phrenic nerve: paralyzed diaphragm
  - Recurrent laryngeal nerve: hoarseness
  - Superior vena cava syndrome
  - Obstruction of SVC causing neck and facial swelling, as well as dyspnea and cough
  - Other symptoms: hoarseness, tongue swelling, epistaxis, and hemoptysis
  - Physical findings: dilated neck veins, increased number of collateral veins covering the anterior chest wall, cyanosis, edema of the face, arms, and chest, Pemberton’s sign (facial flushing, cyanosis, and distension of neck veins upon raising both arms above head)
  - Milder symptoms if obstruction is above the azygos vein
  - Lung apex (Pancoast tumor): Horner’s syndrome, brachial plexus palsy (most commonly C8 and T1 nerve roots)
  - Rib and vertebrae: erosion
  - Distant metastasis to brain, bone, liver, adrenals
- Paraneoplastic syndromes
  - A group of disorders associated with malignant disease, not related to the physical effects of the tumor itself
  - Most often associated with SCLC

Summary

Reduced Lung Cancer Mortality with Low-Dose CT Screening
NEJM 2011;365:699-709
Study: Multicenter, RCT.
Methods: 53,454 participants at high risk for lung cancer (55-74 yr, >30 yr smoking, and smoking cessation for <5 yr) were assigned to undergo three annual screenings with either low dose CT or single-view PA CXR.
Results: A relative reduction in mortality from lung cancer with low-dose CT screening of 20.0% (95% CI 6.6-26.7; p=0.004). Rate of death from any cause was reduced in the low-dose CT group as compared to the CXR group by 8.7% (95% CI 1.2-13.6; p=0.02).

<table>
<thead>
<tr>
<th>Low-dose CT</th>

<tr>
<td>Deaths from lung cancer per 100 K person yr</td>
<td>247</td>
</tr>
</tbody>
</table>

Conclusion: Screening with low-dose CT reduces mortality from lung cancer.

Malignant lung tumors are the most common cause of cancer mortality throughout the world in both men and women.

Endobronchial Ultrasound (EBUS)
- Allows visualization of peri-bronchial structures and distal peripheral lung lesions
- Provides detailed assessment of the airway wall layers
- Allows for guided biopsies of lymph nodes and tumors
- Used for diagnosis and staging.

Investigations

- **Initial diagnosis**
  - Imaging: CXR, CT chest + upper abdomen, PET scan, bone scan
  - Cytology: sputum
  - Biopsy: bronchoscopy, EBUS, CT-guided percutaneous needle biopsy, mediastinoscopy
- **Staging workup**
  - TMN staging system: T - primary tumor (size); N - regional lymph nodes; M - distant metastasis
  - Blood work: electrolytes, LFTs, calcium, ALP
  - Imaging: CXR, CT thorax and upper abdomen, bone scan, neuroimaging
  - Invasive: bronchoscopy (EBUS), mediastinoscopy, mediastinotomy, thoracotomy
  - Screen adenocarcinoma for EGFR mutations

* Depends on clinical vs. pathologic stage

Refer to AJCC Cancer Staging Manual, 7th ed. (2010) for complete TNM classification

Treatment

- Options include surgery, radiotherapy, chemotherapy, and palliative care for end-stage disease
- Surgery not usually performed for SCLC since it is generally non-curable
- Contraindications for surgery
  - Spread to contralateral lymph nodes or distant sites
  - Patients with potentially resectable disease must undergo mediastinal node sampling since CT thorax is not accurate in 20-40% of cases
  - Poor pulmonary status (e.g., unable to tolerate resection of lung)

Horner has a MAP of the Coast
A Pancoast tumor compresses the cervical sympathetic plexus causing a Horner’s syndrome:
Miosis
Anhydrosis
Ptosis

2/3 of primary lung cancer is found in the upper lung; 2/3 of metastases occur in the lower lung (hematogenous spread secondary to increased blood flow to the base of the lung)

Combination treatment may be superior, giving better response rates

Prevention
Smoking cessation
Avoidance of exposures
Early detection

Prevention
• chemotherapy (used in combination with other treatments)
  ▪ common agents: etoposide, platinum agents (e.g. cisplatin), ifosfamide, vincristine, anthracyclines, paclitaxel, irinotecan, gefitinib (an endothelial growth factor receptor inhibitor)
  ▪ complications
    • acute: tumor lysis syndrome, infection, bleeding, myelosuppression, hemorrhagic cystitis (cyclophosphamide), cardiotoxicity (doxorubicin), renal toxicity (cisplatin), peripheral neuropathy (vincristine)
    • chronic: neurologic damage, leukemia, additional primary neoplasms

### Approach to the Solitary Pulmonary Nodule

• see Medical Imaging, MI7

**Definition**

• a round or oval, sharply circumscribed radiographic lesion up to 3-4 cm, which may or may not be calcified, and is surrounded by normal lung
• can be benign or malignant

**Table 31. Differential Diagnosis for Benign vs. Malignant Solitary Nodule**

</tbody>
</table>

**Investigations**

• CXR: always compare with previous CXR
• CT densitometry and contrast enhanced CT of thorax
• sputum cytology: usually poor yield
• biopsy (bronchoscopic or percutaneous) or excision (thoracoscopy or thoracotomy): if clinical and radiographic features do not help distinguish between benign or malignant lesion
  • if at risk for lung cancer, biopsy may be performed regardless of radiographic features
  • if a biopsy is non-diagnostic, whether to observe, re-biopsy, or resect will depend on the level of suspicion
• watchful waiting: repeat CXR and/or CT scan at 3, 6, 12 mo
• PET scan can help distinguish benign from malignant nodules

**Table 32. CXR Characteristics of Benign vs. Malignant Solitary Nodule**

<tr>
<td>Features</td>
<td>Calcified pattern: central, “popcorn” pattern if hamartoma, usually no cavitation; if cavitating, wall is smooth and thin, no other lung pathology</td>
<td>Usually not calcified; if calcified, pattern is eccentric, no satellite lesions, cavitation with thick wall, may have pleural effusions, lymphadenopathy</td>
</tr>
<tr>
<td>Doubling Time</td>
<td>Doubles in &lt;1 mo or &gt;2 yr</td>
<td>Doubles in &gt;1 mo or &lt;2 yr</td>
</tr>
</tbody>
</table>

**Carcinoids**

• Early onset (40-60 yr)
• Most are central and can produce symptoms and signs of bronchial obstruction
• Hemoptysis is present in ~50% of cases

**Hamartomas**

• 10% of benign lung lesions
• Composed of tissues normally present in lung (flat, epithelium, fibrous tissue, and cartilage), but they exhibit disorganized growth
• Peak incidence is age 60, more common in men
• Usually peripheral and clinically silent
• CXR shows clustered “popcorn” pattern of calcification (pathognomonic for hamartoma)

**Pulmonary neoplasms may present as a solitary pulmonary nodule identified incidentally on a radiographic study (~10% of cases) or as symptomatic disease (most cases)**

**Terminology**

• “nodule” < 3 cm
• “mass” > 3 cm
Sleep-Related Breathing Disorders

Hypoventilation Syndromes

- primary alveolar hypoventilation: idiopathic
- obesity-hypoventilation syndrome (Pickwickian syndrome)
- respiratory neuromuscular disorders

Sleep Apnea

Definition
- episodic decreases in airflow during sleep
- quantitatively measured by the Apnea/Hypopnea Index (AHI) = # of apneic and hypopneic events per hour of sleep
- sleep apnea generally accepted to be present if AHI >15

Classification
- obstructive (OSA)
  - caused by transient, episodic obstruction of the upper airway
  - absent or reduced airflow despite persistent respiratory effort
- central (CSA) (see Neurology, N46)
  - caused by transient, episodic decreases in CNS drive to breathe
  - no airflow because no respiratory effort
  - Cheyne-Stokes Respiration: a form of CSA in which central apneas alternate with hyperpneas to produce a crescendo-decrescendo pattern of tidal volume; seen in severe LV dysfunction, brain injury, and other settings (see Figure 2)
- mixed (MSA)
  - features of both OSA and CSA
  - loss of hypoxic and hypercapnic drives to breathe secondary to “resuscitative breathing”: overcompensatory hyperventilation upon awakening from OSA induced hypoxia

Risk Factors
- for OSA: obesity, upper airway abnormality, neuromuscular disease, hypothyroidism, alcohol/sedative use, nasal congestion, sleep deprivation
- for CSA: LV failure, brainstem lesions, encephalitis, encephalopathy, myxedema, high altitude

Signs and Symptoms
- obtain history from spouse/partner
- secondary to repeated arousals and fragmentation of sleep: daytime somnolence, personality and cognitive changes, snoring
- secondary to hypoxemia and hypercapnia: morning headache, polycythemia, pulmonary/systemic HTN, cor pulmonale/CHF, nocturnal angina, arrhythmias

Apnea: absence of breathing for ≥10 s
Hypopnea: excessive decrease in rate or depth of breathing (>50% reduction in ventilation)
Hyperpnea: excessive increase in rate or depth of breathing

Normal Respiratory Changes during Sleep
- Tidal volume decreases
- Arterial CO2 increases (due to decreased minute ventilation)
- Pharyngeal dilator muscles relax causing increased upper airway resistance

Apnea/Hypopnea Index (AHI) = # of apneic and hypopneic events per hour of sleep

Hypoventilation Syndromes

- primary alveolar hypoventilation: idiopathic
- obesity-hypoventilation syndrome (Pickwickian syndrome)
- respiratory neuromuscular disorders

Sleep Apnea

Definition
- episodic decreases in airflow during sleep
- quantitatively measured by the Apnea/Hypopnea Index (AHI) = # of apneic and hypopneic events per hour of sleep
- sleep apnea generally accepted to be present if AHI >15

Classification
- obstructive (OSA)
  - caused by transient, episodic obstruction of the upper airway
  - absent or reduced airflow despite persistent respiratory effort
- central (CSA) (see Neurology, N46)
  - caused by transient, episodic decreases in CNS drive to breathe
  - no airflow because no respiratory effort
  - Cheyne-Stokes Respiration: a form of CSA in which central apneas alternate with hyperpneas to produce a crescendo-decrescendo pattern of tidal volume; seen in severe LV dysfunction, brain injury, and other settings (see Figure 2)
- mixed (MSA)
  - features of both OSA and CSA
  - loss of hypoxic and hypercapnic drives to breathe secondary to “resuscitative breathing”: overcompensatory hyperventilation upon awakening from OSA induced hypoxia

Risk Factors
- for OSA: obesity, upper airway abnormality, neuromuscular disease, hypothyroidism, alcohol/sedative use, nasal congestion, sleep deprivation
- for CSA: LV failure, brainstem lesions, encephalitis, encephalopathy, myxedema, high altitude

Signs and Symptoms
- obtain history from spouse/partner
- secondary to repeated arousals and fragmentation of sleep: daytime somnolence, personality and cognitive changes, snoring
- secondary to hypoxemia and hypercapnia: morning headache, polycythemia, pulmonary/systemic HTN, cor pulmonale/CHF, nocturnal angina, arrhythmias
the typical presentation for OSA is a middle-aged obese male who snores
OSA can be due to neurological disease

Investigations
- sleep study (polysomnography)
  - evaluates sleep stages, airflow, ribcage movement, ECG, SaO2, limb movements
- indications
  - excessive daytime sleepiness
  - unexplained pulmonary HTN or polycythemia
  - daytime hypercapnia
  - titration of optimal nasal CPAP
- assessment of objective response to other interventions

Treatment
- modifiable factors: weight loss, decreased alcohol/sedatives, nasal decongestion, treatment of underlying medical conditions
- OSA or MSA: nasal CPAP, postural therapy (e.g. no supine sleeping), dental appliance, uvulopalatopharyngoplasty, tonsillectomy
- CSA or hypoventilation syndromes: nasal BiPAP/CPAP, respiratory stimulants (e.g. progesterone) in select cases
- tracheostomy rarely required and should be used as last resort for OSA

Complications
- depression, weight gain, decreased quality of life, workplace and vehicular accidents, cardiac complications (e.g. HTN), reduced work/social function

Introduction to Intensive Care
- goal is to provide stabilization for critically ill patients: hemodynamic, respiratory or cardiac instability, or need for close monitoring

Intensive Care Unit Basics

Lines and Catheters
- arterial lines
  - monitor beat-to-beat blood pressure variations, obtain blood for routine ABGs
  - common sites are the radial and femoral arteries
- central venous catheter (central line)
  - administer IV fluids, monitor CVP, insert pulmonary artery catheters
  - administer TPN and agents too irritating for peripheral line
  - common sites: internal jugular vein, subclavian vein, femoral vein
- pulmonary arterial catheter
  - balloon guides the catheter from a major vein to the right heart
  - measures pulmonary capillary wedge pressure (PCWP) via a catheter wedged in distal pulmonary artery
  - PCWP reflects the LA and LV diastolic pressure (barring pulmonary venous or mitral valve disease)
  - indications (now used infrequently due to associated complications)
    - diagnosis of shock states, primary pulmonary HTN, valvular disease, intracardiac shunts, cardiac tamponade, PE
    - assessment of hemodynamic response to therapies
    - differentiation of high- vs. low-pressure pulmonary edema
    - management of complicated MI, multiorgan system failure and/or severe burns, or hemodynamic instability after cardiac surgery
  - absolute contraindications
    - tricuspid or pulmonary valve mechanical prosthesis
    - right heart mass (thrombus or tumor)
    - tricuspid or pulmonary valve endocarditis

</tr>
</tbody>
</table>

Shock

- see Emergency Medicine, ER3
- inadequate tissue perfusion potentially resulting in end organ injury
  - categories of shock:
    - hypovolemic: hemorrhage, dehydration, vomiting, diarrhea, interstitial fluid redistribution
    - cardiogenic: myopathic (myocardial ischemia ± infarction), mechanical, arrhythmic, pharmacologic
    - obstructive: massive PE (saddle embolus), pericardial tamponade, constrictive pericarditis, increased intrathoracic pressure (e.g. tension pneumothorax)
    - distributive: sepsis, anaphylactic reaction, neurogenic, endocrinologic, toxic

Sepsis

- the leading cause of death in noncoronary ICU settings is multi-organ failure due to sepsis
- the predominant theory is that sepsis is attributable to uncontrollable immune system activation

Definitions

- sepsis: the presence of both infection and SIRS (see Table 36)
- severe sepsis: sepsis associated with organ dysfunction, hyperperfusion or hypotension
- septic shock: sepsis with arterial hypotension despite adequate fluid resuscitation
• multiorgan dysfunction syndrome: sepsis in the presence of altered organ function such that homeostasis cannot be maintained without intervention

Signs and Symptoms

Treatment

• identify the cause and source of infection: blood, sputum, urine Gram stain and C&S
• initiate empiric antibiotic therapy
• monitor, restore and maintain hemodynamic function

Early Goal Directed Therapy

• adjustments of cardiac preload, afterload, and contractility to balance oxygen delivery with demand
• should be started immediately and completed within 6 h of recognition of severe sepsis or septic shock
• patient should meet SIRS criteria and sBP <90 mmHg or lactate >35 mg/dL
  1. supplemental oxygen ± intubation and mechanical ventilation
  2. central venous and arterial catheterization
  3. maintain CVP 8-12 mmHg with IV crystalloids/colloids
  4. MAP maintained 65-90 mmHg with the use of vasoactive agents
  5. $S_{a}O_{2}$ <70% then
    • transfusion of red cells until Hct >30%
    • if $S_{a}O_{2}$ <70% after transfusion then use inotropic agents
• supportive oxygenation and ventilation using lung-protective regimen
• early nutritional support: enteral route is used to preserve function of intestinal mucosal barrier
• control hyperglycemia with insulin to decrease infectious complications
• physiologic dose corticosteroid replacement therapy in patients with relative adrenal insufficiency (nonresponders to corticotropin stimulation test)
  • consider in mechanically ventilated septic shock patients with organ dysfunction requiring vasoressors, despite early goal-directed therapy and appropriate antibiotic therapy
• recombinant activated protein C may be considered in patients with severe sepsis or septic shock with an APACHE II score >25 despite early goal-directed therapy and appropriate antibiotic therapy
• DVT/PE prophylaxis
• advanced care planning, including the communication of likely outcomes and realistic goals of treatment with patients and families

Immunogenetics and Disease

- cell surface molecules called HLAs play a role in mediating immune reactions
- MHCs are genes on the short arm of chromosome 6 that encode HLA molecules
- there are three classes of MHCs
- discrete domains of hypervariability within MHC molecules thought to represent “susceptibility determinants”
- certain HLA haplotypes are associated with increased susceptibility to autoimmune diseases

Table 2. Classes of MHCs

Common Investigations in Rheumatology
- general: CBC, electrolytes, Cr
- acute phase reactants: ESR, CRP, ferritin, albumin, fibrinogen, platelets
- complement (C3, C4)
- U/A to detect disease complications (proteinuria, active sediment)
- serology: autoimmune Abs (ANA, anti-dsDNA, anti-Jo-1, anti-Sm, anti-La, anti-Ro, RF, and anti-CCP)
- synovial fluid analysis
- radiology (plain film, CT, MRI, U/S, bone densitometry, angiography, bone scan)

Synovial Fluid Analysis
- synovial fluid is an ultrafiltrate of plasma plus hyaluronic acid; it lubricates joint surfaces and nourishes articular cartilage

Indications
- diagnostic: mandatory if septic arthritis suspected; advised if crystal arthritis or hemorrhages suspected; advised if unexplained effusion in accessible joint
- therapeutic: drainage of blood, purulent or tense effusions; corticosteroid injection

Contraindications
- absolute: open lesion or suspected infection of overlying skin or soft tissue
- relative: bleeding diathesis, thrombocytopenia, prosthetic joint

Most Important Tests of Synovial Fluid (3 Cs)
- ensure synovial fluid is described in terms of color, clarity, viscosity, and quantity
  1. Cell count and differential
  2. Culture and Gram stain (bacteria, mycobacteria, fungi)
  3. Crystal examination (microscopy with polarized light)
    - gout (monosodium urate) → needle-shaped, negatively birefringent (bright yellow)
    - pseudogout (calcium pyrophosphate dihydrate) → rhomboid-shaped, positively birefringent (pale blue)

</table>
### Septic Arthritis

- for any acute monoarticular arthritis, one must rule out septic etiology; consider empiric antibiotic treatment until septic arthritis is excluded by history, physical exam, and synovial fluid analysis
- poor prognostic factors: older age, immunocompromised, delay in treatment, previously damaged joint, joint prosthesis
- see Infectious Diseases for Gonococcal Arthritis, ID15/Orthopedics, OR10

### Degenerative Arthritis: Osteoarthritis

**Definition**
- progressive deterioration of cartilage and bone due to failed repair of joint damage caused by stresses on the joint

**Classification (Based on Etiology)**
- primary (idiopathic)
  - most common, unknown etiology
- secondary
  - post-traumatic or mechanical
  - post-inflammatory (e.g. RA) or post-infectious
  - heritable skeletal disorders (e.g. scoliosis)
  - endocrine disorders (e.g. acromegaly, hyperparathyroidism, hypothyroidism)
  - metabolic disorders (e.g. gout, pseudogout, hemochromatosis, Wilson’s disease, ochronosis)
  - neuropathic (e.g. Charcot joints)
    - atypical joint trauma due to peripheral neuropathy (e.g. DM, syphilis)
  - AVN
  - other (e.g. congenital malformation)

**Pathophysiology**
- deterioration of articular cartilage due to local biomechanical factors, which leads to joint trauma and release of proteolytic and collagenolytic enzymes
  - OA develops when cartilage catabolism > synthesis
  - loss of proteoglycans and water exposes underlying bone
- abnormal local bone metabolism further damages joint
- altered joint function and damage
- synovitis is secondary to cartilage damage; therefore, may see small effusions in OA

**Epidemiology**
- most common arthropathy
- increased prevalence with increasing age (35% of 30 yr olds, 85% of 80 yr olds)

**Risk Factors**
- genetic predisposition, advanced age, obesity (for knee OA), female, trauma

**Signs and Symptoms**
- localized to affected joints (not a systemic disease)
- pain is often insidious, gradually progressive, with intermittent flares and remissions

<table>
<thead>
<tr>
<th>Signs</th>
<th>Symptoms</th>
</tr>
</thead>
<tbody>
<tr>
<td>Joint line tenderness; stress pain ± joint effusion</td>
<td>Joint pain with motion; relieved with rest</td>
</tr>
<tr>
<td>Bony enlargement at affected joints</td>
<td>Short duration of stiffness (&lt;1/2 h) after immobility</td>
</tr>
<tr>
<td>Malalignment/deformity (angulation)</td>
<td>Joint instability/buckling</td>
</tr>
<tr>
<td>Limited ROM</td>
<td>Joint locking due to “joint mouse” (bone or cartilage fragment)</td>
</tr>
<tr>
<td>Crepitus on passive ROM</td>
<td>Loss of function or other internal derangements (e.g. meniscal tear)</td>
</tr>
<tr>
<td>Inflammation (mild if present)</td>
<td>Periarticular muscle atrophy</td>
</tr>
</tbody>
</table>

**Joint Involvement**
- asymmetric
- hand
  - DIP (Heberden’s nodes = osteophytes → enlargement of joints)
  - PIP (Bouchard’s nodes)
  - CMC (usually thumb squaring)
  - 1st MCP (other MCPs are usually spared)

*Figure 3. Common sites of joint involvement in OA*

- Hand (DIP, PIP, 1st CMC)
- Hip
- Knee
- 1st MTP
- L-spine (L4-L5, L5-S1)
- C-spine
- Uncommon: ankle, shoulder, elbow, MCP, rest of wrist

*Figure 4. Hand findings in OA*

- 1. Thumb squaring
- 2. Heberden’s nodes
- 3. Bouchard’s nodes

Obesity is linked to OA in the knee as well as CMC, which suggests a systemic inflammatory component to OA

Septic arthritis is a medical emergency; it leads to rapid joint destruction, and there is a 10-15% risk of mortality

OA of MCP joints can be seen in hemochromatosis or chondrocalcinosis
• hip
  ▪ usually presents as groin pain ± dull or sharp pain in the trochanteric area, internal rotation
  and abduction are lost first
  ▪ pain can radiate to the anterior thigh, but generally does not go below the knee
• knee
  ▪ initial narrowing of one compartment, medial > lateral; seen on standing x-rays, often
  patellar-femoral joint involved
• foot
  ▪ common in first MTP and midfoot
• lumbar spine
  ▪ very common, especially L4-L5, L5-S1
  ▪ degeneration of intervertebral discs and facet joints
  ▪ reactive bone growth can contribute to neurological impingement (e.g. sciatica, neurogenic
  claudication) or spondylolisthesis (forward or backward movement of one vertebra over
  another)
• cervical spine
  ▪ commonly presents with neck pain that radiates to scapula, especially in mid-lower cervical
  area (C5 and C6)

Investigations
• blood work
  ▪ normal CBC and ESR, CRP
  ▪ negative RF and ANA
• radiology: 4 hallmark findings
• synovial fluid: non-inflammatory (see Table 8)

Treatment
• presently no treatment alters the natural history of OA
• non-pharmacological therapy
  ▪ weight loss (minimum 5-10 lb loss) if overweight
  ▪ physiotherapy: heat/cold, low impact exercise programs
  ▪ occupational therapy: aids, splints, cane, walker, bracing
• pharmacological therapy (see Table 32)
  ▪ oral: acetaminophen/NSAIDs, glucosamine ± chondroitin (nutraceuticals not proven)
  ▪ joint injections: corticosteroid, hyaluronic acid (questionable benefit)
  ▪ topical: capsaicin, NSAIDs
• surgical treatment
  ▪ joint debridement, osteotomy, total and/or partial joint replacement, fusion
  (see Orthopedics, OR28)

SEROPOSITIVE RHEUMATIC DISEASE

• diagnosis vs. classification in rheumatology
  ▪ diagnostic criteria are often dependent on disease progression and evolution over time, as
  early objective measures are often unavailable
  ▪ classification criteria are derived from studying patients with long-term diseases and clear
  diagnoses in order to determine which criteria have good specificity in the early prediction
  of certain diagnoses
  ▪ seropositive arthropathies are characterized by the presence of a serologic marker such as
  positive RF or ANA
  ▪ a small subset of the vasculitides, the small vessel ANCA-associated vasculitides, have a
  measurable serological component, but even these are often considered a separate entity from
  seropositive disease by experts

Blood Work
• general: CBC, Cr
• acute phase reactants: ESR, CRP, ferritin, albumin, complement (C3 and C4), fibrinogen,
  note: C3, C4 often decrease in active SLE
• autoantibodies

Urinalysis
• proteinuria, active sediment

Synovial Fluid Analysis
• see Table 8

Radiology
• plain film, CT, MRI, U/S, bone densitometry, angiography, and bone scan

Meta-Analysis: Chondroitin for Osteoarthritis of the Knee and Hip
Cochrane DB Syst Rev 2009;CD005328
Population: Patients with osteoarthritis (OA) of the knee.
Intervention: Intraarticular (IA) corticosteroid injection.
Results: 20 RCTs and quasi-RCTs (n=1,973). IA corticosteroids were more effective than placebo
for pain relief and global assessment at 1 wk post-injection. There was significant pain reduction
at 2 and 3 wk, but no benefit for pain and function beyond 4 wk post-injection. There was no benefit
for global function beyond 1 wk post-injection. There were higher rates of pain reduction at 4 wk
post-injection for tranexamate hexacetonide vs. betamethasone. There was no difference between
IA corticosteroids and joint lavage in outcomes or safety. Hyaluronic acid injections showed better
response than IA corticosteroids between 5 and 13 wk post-injection.
Conclusion: IA corticosteroid injection is effective for the short-term treatment of OA of the knee
with few side effects. Hyaluronic acid therapy can provide more durable results.

Glucosamine Therapy for Treating Osteoarthritis
Cochrane DB Syst Rev 2009;CD003246
Study: Meta-analysis of 25 RCTs (n=4,963) examining the efficacy of glucosamine on OA.
Results: Collectively the 25 RCTs favored glucosamine over placebo for total reduction in pain
with 22% improvement as well as improvement in function using the Lequesne index. However, results
were not uniformly positive. Only the glucosamine containing Rotta preparation was found to be
significant. Rotta preparation also showed that glucosamine was able to slow radiological evidence
of OA over a 3 yr period. Glucosamine had an excellent safety profile.
Conclusion: Rotta preparation of glucosamine was superior to placebo in the treatment of pain
and functional impairment resulting from OA.

#### Rheumatoid Arthritis

**Definition**
- Chronic, symmetric, erosive synovitis of peripheral joints (e.g. wrists, MCPs, MTPs)
- Characterized by a number of extra-articular features

**Table 12. Classification Criteria for RA**

<table>

Arthritis Rheum 2010;62:2569-2581

RA is an independent risk factor for atherosclerosis and CV disease; RA is associated with increased overall mortality/morbidity from all causes: CV disease, neoplasm (especially lymphoma), infection

Common Presentation
- Morning stiffness >1 h, improves with use
- Symmetric joint involvement
- Initially involves small joints of hands and feet
- Constitutional symptoms

1987 American Rheumatism Association RA Criteria

At least 4 of:
- Morning stiffness >1 h for >6 wk
- Arthritis ≥3 joints for >6 wk
- Arthritis of hand joints for >6 wk
- Arthritis of foot joints for >6 wk
- Symmetric arthritis for >6 wk
- Rheumatoid nodules
- Serum RF positive
- Radiographic changes (erosions or periarticular osteosclerosis)

Criteria are 91-94% sensitive and 89% specific for RA
Pathophysiology
- autoimmune disorder, unknown etiology
- hallmark of RA is hypertrophy of the synovial membrane
  - activated rheumatoid synovium (pannus) grows into and over the articular surface; inflammatory mediators lead to release of metalloproteinases and collagenases resulting in destruction of articular cartilage and subchondral bone
- two theories attempt to explain chronic remissions and exacerbations seen in RA
  - sequestered Ag
    - during inflammation, immune complexes (ICs) are deposited at avascular cartilage-bone junction → immune complexes are released as further cartilage breaks down → triggers inflammatory cascade
  - molecular mimicry
    - cartilage damage → altered cartilage resembles undefined offending agent → triggers inflammatory cascade

Epidemiology
- prevalence 1% of adult population
- F:M = 3:1
- age of onset 20-40 yr
- genetic predisposition: HLA-DR4/DR1 association (93% of patients have either HLA type)

Signs and Symptoms
- variable course of exacerbations and remissions
- morning stiffness >1 h, improves with use, increases with rest
- may have joint pain with activity
- symmetric joint involvement
- joint swelling, tender joints
- constitutional symptoms: profound fatigue; rarely myalgia or weight loss
- extra-articular features (EAF)
- complications of chronic synovitis
  - signs of mechanical joint damage: loss of motion, instability, deformity, crepitus, joint deformities
    - swan neck deformity, boutonnière deformity
    - ulnar deviation of MCP, radial deviation of wrist joint
    - hammer toe, mallet toe, claw toe
    - flexion contractures
  - atlanto-axial and subaxial subluxation
  - C-spine instability
  - neurological impingement (long tract signs)
  - difficult/dangerous intubation: risk of worsening subluxation and damage to spinal cord
  - limited shoulder mobility, spontaneous tears of the rotator cuff leading to chronic spasm
  - tenosynovitis → may cause rupture of tendons
  - carpal tunnel syndrome
  - ruptured Baker's cyst (outpouching of synovium behind the knee); presentation similar to acute DVT

Classification of Global Functional Status in RA
- Class I: able to perform usual ADLs (self-care, vocational, avocational)
- Class II: able to perform self-care and vocational activities, restriction of avocational activities
- Class III: able to perform self-care, restriction of vocational and avocational activities
- Class IV: limited ability to perform self-care, vocational, and avocational activities

Figure 5. Common sites of joint involvement in RA

Figure 6. Joint deformities

Syndromes in RA
- SS (common): keratoconjunctivitis sicca and xerostomia (dry eyes and mouth)
- Caplan’s syndrome (rare): multiple pulmonary nodules and pneumoconiosis
- Felty’s syndrome (rare): arthritis, splenomegaly, neutropenia
Investigations
- blood work
  - RF sensitivity ~80% but non-specific; may not be present at onset of symptoms
  - anti-CCP: sensitivity ~80% but more specific; may precede onset of symptoms
  - increased disease activity is associated with decreased Hb (anemia of chronic disease), increased platelets, ESR, CRP, and RF
- imaging
  - x-rays may be entirely normal at onset
  - first change is periarticular osteopenia, followed by erosions
  - U/S, MRI may be used to image hands to detect early synovitis and erosions

Treatment
- goals of therapy: remission or lowest possible disease activity
  - control disease activity
  - relieve pain and stiffness
  - maintain function and lifestyle
  - prevent or control joint damage
  - key is early diagnosis and early intervention with DMARDs
  - "window of opportunity" = early treatment within first 3 mo of disease may allow better control/remission

Education
- The Arthritis Society (Canada), Arthritis Foundation (U.S.), The Rheumatoid Patient Foundation for educational resources

Behavioral
- exercise program (isometrics and active, gentle ROM exercise during flares, aquatic/aerobic/strengthening exercise between flares), assistive devices as needed
- job modification may be necessary

Pharmacologic
1. DMARDs and Biologics (see Table 33)
   - DMARDs: standard of care and should be started as soon as possible
   - treatments guided by disease severity and prognostic features
   - MTX is the gold standard and is first-line unless contraindicated
   - potential toxicities: GL, hematologic, hepatic (liver enzymes), pulmonary, teratogenic
   - if inadequate response (3-6 mo) → combine or switch
   - add-ons include: hydroxychloroquine, sulfasalazine, leflunomide
   - biologics: indicated if inadequate response to DMARDs
     - can be combined with DMARD therapy
     - agents include infliximab, etanercept, adalimumab, abatacept, rituximab, tocilizumab
     - reassess every 3-6 mo and monitor disease severity

2. Reducing Inflammation and Pain
   - NSAIDs
     - individualize according to efficacy and tolerability
     - contraindicated or cautioned in some patients (e.g. PUD, ischemic cardiac disease, pregnancy); add acetaminophen ± opioid prn for synergistic pain control
   - corticosteroids
     - local
       - IA injections to control symptoms in a specific joint
       - systemic (prednisone)
         - low dose (5-10 mg/d) useful for short-term to improve symptoms if NSAIDs ineffective, to bridge gap until DMARD takes effect
         - for severe RA, low dose prednisone can be added to DMARDs
         - do baseline DEXA bone density scan and consider bone supportive pharmacologic therapy if using corticosteroids >3 mo at >7.5 mg/d
         - cautions/contraindications: active infection, TB, osteoporosis, HTN, gastric ulcer, DM

Follow-Up Management of Established RA
- follow-up every 3-6 mo, then 6-12 mo after inflammation has been suppressed
- examine joints for active inflammation – if active, consider adjusting medications, referral to specialist, PT/OT
- if assessment reveals joint damage – consider analgesia, referral to PT/OT, surgical options

Surgical Therapy
- indicated for structural joint damage
- surgical options include: synovectomy, joint replacement, joint fusion, reconstruction/tendon repair

Diagnosis of Systemic Lupus Erythematosus

- MD SOAP BRAIN
  - Malar rash
  - Discoid rash
  - Oral ulcers
  - Photosensitivity
  - Blood
  - Renal
  - Arthritis
  - Immune
  - Neurologic

Side Effects of Steroids
- Weight gain
- Osteoporosis
- AVN
- Cataracts, glaucoma
- PUD
- Susceptibility to infection
- Easy bruising
- Acne
- HTN
- Hyperlipidemia
- Hypokalemia, hyperglycemia
- Mood swings

Comparison of Treatment Strategies in Early Rheumatoid Arthritis

- Poor prognostic features of RA include: young age of onset, high RF titer, elevated ESR, activity of >20 joints, and presence of extra-articular features

- Side Effects of Steroids
  - Weight gain
  - Osteoporosis
  - AVN
  - Cataracts, glaucoma
  - PUD
  - Susceptibility to infection
  - Easy bruising
  - Acne
  - HTN
  - Hyperlipidemia
  - Hypokalemia, hyperglycemia
  - Mood swings

- Only DMARDs (not analgesics or NSAIDs) alter the course of RA

- Comparison of Treatment Strategies in Early Rheumatoid Arthritis
  - Study: RCT of 508 patients comparing 4 different treatment strategies for early RA (known as the BEST trial).
  - Intervention:
    - Group 1: Sequential Monotherapy with traditional DMARDs
    - Group 2: Step-Up Combination Therapy
    - Group 3: Initial Combination Therapy with prednisone (high dose)
    - Group 4: Initial Combination Therapy with infliximab
  - Results: Patients in groups 3 and 4 responded faster and had significantly greater overall change in physical function scores after the first year of treatment. By end of the second year, groups 1 and 2 had achieved a similar response to groups 3 and 4. Groups 3 and 4 also showed significantly less radiologic progression of their disease over 2 yr than groups 1 and 2. There were no significant differences in toxicity levels between the 4 groups.
  - Conclusion: Initial combination therapy with prednisone or infliximab results in faster response rates. Whether faster initial response rates leads to better long-term disease outcomes has not yet been studied.

Diagnostic Criteria of SLE

- MD SOAP BRAIN
  - Malar rash
  - Discoid rash
  - Oral ulcers
  - Photosensitivity
  - Blood
  - Renal
  - Arthritis
  - Immune
  - Neurologic
Systemic Lupus Erythematosus

- see Nephrology, NP24 and Dermatology, D38 for additional details

Definition
- chronic inflammatory multi-system disease of unknown etiology
- characterized by production of autoantibodies and diverse clinical manifestations

Table 14. Diagnostic Criteria of SLE*

</tbody>
</table>

*Note: “4, 7, 11” rule = ≤4 (or more) out of 11 criteria (4 lab, 7 clinical) must be present, serially or simultaneously, for diagnosis American College of Rheumatology, 1997 update

Etiology and Pathophysiology
- production of autoantibodies causing multi-organ inflammation
- multi-factorial etiology
- genetics
  - common association with HLA-B8/DR3; ~10% have positive family history
- estrogen
  - pre-pubertal and post-menopausal women have similar incidence to men
  - men with SLE have higher concentration of estrogenic metabolites
- infection
  - viral (non-specific stimulant of immune response)
- drug-induced
  - anti-hypertensives (hydralazine), anti-convulsants (phenytoin), anti-arrhythmics (procainamide), isoniazid, biologics, oral contraceptive pills
  - anti-histone Ab are commonly seen in drug-induced SLE
- symptoms resolve with discontinuation of offending drug

Epidemiology
- prevalence: 0.05% overall
- F:M = 10:1
- age of onset in reproductive yr (13–40)
- more common and severe in African Americans and Asians
- bimodal mortality pattern
  - early (within 2 yr)
    - active SLE, active nephritis, infection secondary to steroid use
  - late (>10 yr)
    - inactive SLE, inactive nephritis, atherosclerosis likely due to chronic inflammation

Signs and Symptoms
- characterized by periods of exacerbation and remission
Table 15. Symptoms of SLE

<table>
<thead>
<tr>
<th>System</th>
<th>Symptoms</th>
</tr>
</thead>
<tbody>
<tr>
<td>Systemic</td>
<td>Fatigue, malaise, weight loss, fever, lymphadenopathy</td>

</tr>
<tr>
<td>Neurologic</td>
<td>H/A, depression, psychosis, seizures, cerebritis, transverse myelitis, peripheral neuropathy, stroke</td>
</tr>
</tbody>
</table>

Investigations
- blood work: ANA (sensitivity 98%, but poor specificity → used as a screening test, ANA titres are not useful to follow disease course)
- anti-dsDNA and anti-Sm are specific (95-99%)
- anti-dsDNA titer and serum complement (C3, C4) are useful to monitor treatment response in patients who are clinically and serologically concordant
  - anti-dsDNA increases and C3 and C4 decrease with disease activity
- antiphospholipid Ab (anti-cardiolipin Ab and SLE anticoagulant), may cause increased risk of clotting and increased aPTT

Treatment
- goals of therapy
  - treat early and avoid long-term steroid use, if unavoidable see Endocrinology, E42 for osteoporosis management
  - if high doses of steroids necessary for long-term control, add steroid-sparing agents and taper when possible
  - treatment is tailored to organ system involved and severity of disease
  - all medications used to treat SLE require periodic monitoring for potential toxicity
- dermatologic
  - sunscreen, avoid UV light and estrogens
  - topical steroids, hydroxychloroquine
- musculoskeletal
  - NSAIDs ± gastroprotective agent for arthritis (also beneficial for pleuritis and pericarditis)
  - hydroxychloroquine improves long-term control and prevents flares
  - bisphosphonates, calcium, vitamin D to combat osteoporosis
- organ-threatening disease
  - high-dose oral prednisone or IV methylprednisolone in severe disease
  - steroid-sparing agents: azathioprine, MTX, mycophenolate
  - IV cyclophosphamide for serious organ involvement (e.g. cerebritis or SLE nephritis)

Antiphospholipid Antibody Syndrome

Definition
- multi-system vasculopathy manifested by recurrent thromboembolic events, spontaneous abortions, and thrombocytopenia
- often presents with migraine-type headaches
- circulating antiphospholipid autoantibodies interfere with coagulation cascade
- primary APLA: occurs in the absence of other disease
- secondary APLA: occurs in the setting of a connective tissue disease (including SLE), malignancy, drugs (hydralazine, procainamide, phenytoin, interferon, quinidine), and infections (HIV, TB, hepatitis C, infectious mononucleosis)
- catastrophic APLA: development within 1 wk of small vessel thrombotic occlusion in ≥3 organ systems with positive antiphospholipid Ab (high mortality)
Table 16. Classification Criteria of APLA*

</tbody>
</table>

*1 clinical and 1 laboratory criteria must be present for diagnosis

Signs and Symptoms
- see clinical criteria in Table 16
- hematologic
  - thrombocytopenia, hemolytic anemia, neutropenia
- dermatologic
  - livedo reticularis, Raynaud’s phenomenon, purpura, leg ulcers, and gangrene

Treatment
- thrombosis
  - lifelong anti-coagulation with warfarin
  - target INR 2.0-3.0 for first venous event, >3.0 for recurrent and/or arterial event
- recurrent fetal loss
  - heparin/low molecular weight heparin ± Aspirin® during pregnancy
- catastrophic APLA
  - high-dose steroids, anti-coagulation, cyclophosphamide, plasmapheresis

Scleroderma

Definition
- a non-inflammatory autoimmune disorder characterized by widespread small vessel vasculopathy and fibrosis

Figure 8. Forms of scleroderma

Table 17. Classification Criteria of Systemic Sclerosis*

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Description</th>

</tr>
<tr>
<td>Bibasilar</td>
<td>Pulmonary fibrosis</td>
</tr>
</tbody>
</table>

*Diagnosed if 1 major or 2 minor criteria must be present

American Rheumatism Association, 1980

Etiology and Pathophysiology
- idiopathic vasculopathy (not vasculitis) leading to atrophy and fibrosis of tissues
  - intimal proliferation and media mucinous degeneration → progressive obliteration of vessel lumen → fibrotic tissue
  - resembles malignant HTN
Epidemiology
- F:M = 3-4:1, peaking in 5th and 6th decades
- associated with HLA-DR1
- associated with environmental exposure (silica, epoxy resins, toxic oil, aromatic hydrocarbons, polyvinyl chloride)
- limited systemic sclerosis has a higher survival prognosis (>70% at 10 yr) than diffuse systemic sclerosis (40-60% at 10 yr)

Signs and Symptoms

Table 18. Clinical Manifestations of Scleroderma

<table>
<thead>
<tr>
<th>System</th>

</tr>
<tr>
<td></td>
<td>Proximal weakness Z° to disuse, atrophy, low grade myopathy</td>
</tr>
<tr>
<td>Endocrine</td>
<td>Hypothyroidism</td>
</tr>
</tbody>
</table>

Investigations
- blood work
  - CBC, Cr, ANA
  - anti-topoisomerase 1/anti-Scl-70: specific but not sensitive for diffuse systemic sclerosis
  - anti-centromere: favors diagnosis of CREST (limited systemic sclerosis)
- PFT
  - assess for pulmonary HTN or interstitial lung disease
- imaging
  - CXR for fibrosis, echo for pulmonary HTN

Treatment
- dermatologic
  - good skin hygiene
  - low-dose prednisone (>20 mg may provoke renal crisis if susceptible), MTX (limited evidence)
- vascular
  - patient education on cold avoidance
  - vasodilators (CCBs, local nitroglycerine cream, systemic PGE2 inhibitors, PDE5 inhibitors)
- gastrointestinal
  - GERD: PPIs are first line, then H2-receptor agonists
  - small bowel bacterial overgrowth: broad spectrum antibiotics (tetracycline, metronidazole)
- renal disease
  - ACE inhibitors for hypertensive crisis
- pulmonary
  - early interstitial disease: cyclophosphamide
  - pulmonary HTN: vasodilators e.g. bosentan (Tracleer*), epoprostenol (Flolan*), PDE5 inhibitors
- cardiac
  - pericarditis: systemic steroids
- musculoskeletal
  - arthritis: NSAIDs
  - myositis: systemic steroids
Idiopathic Inflammatory Myopathy

Definition
- autoimmune diseases characterized by proximal muscle weakness ± pain
- muscle becomes damaged by a non-suppurative lymphocytic inflammatory process

Classification
- PM/DMM
- adult and juvenile form
- associated with malignancy
  - increased risk of malignancy: age >50, DMM>PM, normal CK, refractory disease
  - 2.4-6.5 fold increased risk of underlying malignancy usually in internal organs
- associated with other connective tissue disease, Raynaud’s phenomenon, autoimmune disorders
- inclusion body myositis
  - age >50, M>F, slowly progressive, vacuoles in cells on biopsy
  - suspect when patient unresponsive to treatment
  - distal as well as proximal muscle weakness
  - muscle biopsy positive for inclusion bodies

POLYMYOSITIS/DERMATOMYOSITIS

Table 19. Classification Criteria for PM/DMM

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Symmetric proximal muscle weakness</td>
<td>Typical involvement of shoulder girdle and hip girdle</td>
</tr>
<tr>
<td>2. Elevated muscle enzymes</td>
<td>↑ CK, aldolase, LDH, AST, ALT</td>
</tr>
<tr>
<td>3. EMG changes</td>
<td>Short polyphasic motor units, high frequency repetitive discharge, insertional irritability</td>
</tr>
<tr>
<td>4. Muscle biopsy</td>
<td>Segmental fiber necrosis, basophilic regeneration, perivascular inflammation (DMM), endomysial inflammation (PM) and atrophy</td>
</tr>
<tr>
<td>5. Typical rash of dermatomyositis</td>
<td>Required for diagnosis of DMM (see below)</td>
</tr>
</tbody>
</table>

Etiology and Pathophysiology
- PM is CD8 cell-mediated muscle necrosis, found in adults
- DMM is B-cell and CD4 immune complex-mediated peri-fascicular vascular abnormalities

Signs and Symptoms
- progressive symmetrical proximal muscle weakness (shoulder and hip) developing over weeks to months
- difficulty lifting head off pillow, arising from chair, climbing stairs
- dermatological
  - DMM has characteristic dermatological features (F>M, children and adults)
    - Gottron’s papules
      - pink-violaceous, flat-topped papules overlying the dorsal surface of the interphalangeal joints
    - Gottron’s sign
      - erythematous, smooth or scaly patches over the dorsal IPs, MCPs, elbows, knees, or medial malleoli
    - heliotrope rash: violaceous rash over the eyelids, usually with edema
    - shawl sign: erythematous rash over neck, upper chest, and shoulders
    - mechanic’s hands: dark, dry, thick scale on palmar and lateral surface of digits
    - periungual erythema
- cardiac
  - dysrhythmias, CHF, conduction defect, ventricular hypertrophy, pericarditis
- gastrointestinal
  - oropharyngeal and lower esophageal dysphagia, reflux
- pulmonary
  - weakness of respiratory muscles, interstitial lung disease, aspiration pneumonia

Investigations
- blood work: CK, ANA, anti-Jo-1 (DMM), anti-Mi-2, anti-SRP
- imaging: MRI may be used to localize biopsy site
- EMG, muscle biopsy

Treatment
- non-pharmacological: physical therapy and occupational therapy
- pharmacological treatment
  - high-dose corticosteroid (1-2 mg/kg/d) and slow taper
  - add immunosuppressive agents (azathioprine, MTX, cyclosporine)
  - intravenous immunoglobulin if severe or refractory
  - hydroxychloroquine for DMM rash
• malignancy surveillance
  ▪ detailed history and physical (breast, pelvic, and rectal exam)
  ▪ CXR, abdominal and pelvic U/S, fecal occult blood, Pap test, mammogram ± CT scan
    (thoracic, abdominal, pelvic)

### Sjögren’s Syndrome

**Definition**
- autoimmune condition characterized by dry eyes (keratoconjunctivitis sicca/xerophthalmia) and dry mouth (xerostomia), caused by lymphocytic infiltration of salivary and lacrimal glands
- may evolve into systemic disorder with diminished exocrine gland activity in respiratory tract and skin
- primary and secondary form (associated with RA, SLE, DMM, and HIV)
- incidence estimated at 4/100,000 people
- 90% of cases are among females
- mean age of diagnosis is 40-60 yr

**Table 20. Classification Criteria for SS***

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Dry eye symptoms</td>
<td>Dry &gt;3 mo, foreign body sensation, or requiring tear substitutes</td>
</tr>
<tr>
<td>2. Dry mouth symptoms</td>
<td>Dry &gt;3 mo, swollen salivary glands, or requiring liquids to swallow food</td>
</tr>
<tr>
<td>3. Dry eye signs</td>
<td>Schirmer test (to assess tear flow) or slit lamp exam with Rose Bengal stain</td>
</tr>
<tr>
<td>4. Dry mouth signs</td>
<td>Low salivary flow, sialography</td>
</tr>
<tr>
<td>5. Salivary gland biopsy</td>
<td>Focal lymphocytic sialoadenitis</td>
</tr>
<tr>
<td>6. Autoantibodies</td>
<td>anti-Ro and/or anti-La, ANA, RF</td>
</tr>
</tbody>
</table>

*Diagnosed if 4 of the above criteria present, one of which includes salivary gland biopsy or autoantibodies
Ann Rheum Dis 2002;61:554-558

**Signs and Symptoms**
- "sicca complex": dry eyes (keratoconjunctivitis sicca/xerophthalmia), dry mouth (xerostomia)
- staphylococcus blepharitis
- dental caries, oral candidiasis, angular cheilitis (inflammation and fissuring at the labial commissures of the mouth)
- systemic complications
  ▪ sinusitis, autoimmune thyroid dysfunction
  ▪ arthralgias, arthritis
  ▪ subclinical diffuse interstitial lung disease, xerotrachea leading to chronic dry cough
  ▪ renal disease, glomerulonephritis
  ▪ palpable purpura, vasculitis
  ▪ peripheral neuropathy
  ▪ lymphoma risk greatly increased

**Treatment**
- ocular
  ▪ artificial tears or surgical punctal occlusion for dry eyes
- oral
  ▪ good dental hygiene, hydration
  ▪ agents that stimulate salivary flow (e.g. pilocarpine)
  ▪ topical nystatin or clotrimazole x 4-6 wk for oral candidiasis
- systemic
  ▪ e.g. hydroxychloroquine, corticosteroids

### Mixed Connective Tissue Disease

- syndrome with features of 3 different connective tissue diseases (e.g. SLE, scleroderma, PM)
- common symptoms: Raynaud’s phenomenon, swollen fingers
- blood work: anti-RNP (see Table 10)
- treatment is generally guided by the severity of symptoms and organ system involvement
- prognosis
  ▪ 50-60% will evolve into SLE
  ▪ 40% will evolve into scleroderma
  ▪ only 10% will remain as MCTD for the rest of their lives
  ▪ cardiac involvement (dysrhythmia) common, renal or lung involvement rare

### Overlap Syndrome

- syndrome with sufficient diagnostic features of 2+ different connective tissue diseases
Vasculitides

- inflammation and subsequent necrosis of blood vessels leading to tissue ischemia or infarction
- any organ system can be involved
- keys to diagnosis
  - clinical suspicion: suspect in cases of unexplained multiple organ ischemia or systemic illness with no evidence of malignancy or infection
  - labs non-specific: anemia, increased WBC and ESR, abnormal U/A
  - biopsy if tissue accessible
  - angiography if tissue inaccessible
- treatment generally involves corticosteroids and/or immunosuppressive agents

<td></td>
</tr>
<tr>
<td>Buerger’s disease</td>
<td>Inflammation secondary to pathological clotting, affects small and medium-sized vessels of distal extremities, may lead to distal claudication and gangrene, most important etiologic factor is cigarette smoking</td>
</tr>
<tr>
<td>(“Thromboangiitis Obliterans”)</td>
<td>Most common in young Asian males</td>
</tr>
<tr>
<td>Behçet’s disease</td>
<td>Leukocytoclastic vasculitis, multi-system disorder presenting with ocular involvement (uveitis), recurrent oral and genital ulceration, venous thrombosis, skin and joint involvement, more common in Mediterranean and Asia, average age 30s, M&gt;F</td>
</tr>
<tr>
<td>Vasculitis mimicry</td>
<td>Cholesterol emboli, atrial myxoma</td>
</tr>
</tbody>
</table>
Small Vessel Non-ANCA Associated Vasculitis

PREDOMINANTLY CUTANEOUS VASCULITIS
- subdivided into
  - drug-induced vasculitis
  - serum sickness reaction
  - vasculitis associated with other underlying primary diseases

Etiology and Pathophysiology
- cutaneous vasculitis following
  - drug exposure (allopurinol, gold, sulfonamides, penicillin, phenytoin)
  - viral or bacterial infection
  - idiopathic causes
- small vessels involved (post-capillary vessels most frequently)
- usually causes a leukocytoclastic vasculitis: debris from neutrophils around vessels
- sometimes due to cryoglobulins which precipitate in cold temperatures

Signs and Symptoms
- palpable purpura ± vesicles and ulceration, urticaria, macules, papules, bullae, subcutaneous nodules
  - renal or joint involvement may occur, especially in children

Investigations
- vascular involvement (both arteriole and venule) established by skin biopsy

Treatment
- stop possible offending drug
- corticosteroids ± immunosuppressive agents
- usually self-limiting

Small Vessel ANCA-Associated Vasculitis

GRANULOMATOSIS WITH POLYANGIITIS (GPA, formerly known as Wegener’s Granulomatosis)

Definition
- granulomatous inflammation of vessels that may affect the upper airways (rhinitis, sinusitis), lungs (pulmonary nodules, infiltrates), and kidneys (glomerulonephritis, renal failure)
- highly associated with c-ANCA
- incidence 5 per 100,000; more common in Northern latitudes

Table 22. Classification Criteria for GPA*

<table>
<thead>
<tr>
<th>Criteria</th>

<td>Microscopic hematuria ± RBC casts</td>
</tr>
<tr>
<td>4. Biopsy of involved tissue</td>
<td>Lungs show granulomas, kidneys show necrotizing segmental glomerulonephritis</td>
</tr>
</tbody>
</table>

*Diagnosed if 2 or more of the above 4 criteria present
American College of Rheumatology, 1990
Etiology

- pathogenesis depends on genetic susceptibility and environmental triggers (e.g. infection)
  - dysregulated immune response due to loss of B and T-cell tolerance
  - acute vascular injury mediated by neutrophils and monocytes

Signs and Symptoms

- systemic
  - malaise, fever, weakness, weight loss
- HEENT
  - sinusitis or rhinitis, nasal crusting and bloody nasal discharge, saddle nose deformity
  - proptosis due to: inflammation/vasculitis involving extra-ocular muscles, granulomatous retrobulbar space occupying lesions or direct extension of masses from the upper respiratory tract
  - hearing loss due to involvement of CN VIII
- pulmonary
  - cough, hemoptysis, granulomatous upper respiratory tract masses
- renal
  - hematuria
- other
  - joint, skin, eye complaints, vasculitic neuropathy

Investigations

- blood work: anemia (normal MCV), increased WBC, increased Cr, increased ESR, elevated platelet count, ANCA (PR3 > MPO)
- U/A: proteinuria, hematuria, RBC casts
- CXR: pneumonitis, lung nodules, infiltrations, cavitary lesions
- biopsy: renal (segmental necrotizing glomerulonephritis), lung (granulomas, tracheobronchial erosion)
- possible decline in c-ANCA and ESR used to monitor response to treatment in some patients

Treatment

- prednisone 1 mg/kg/d PO for 3-6 mo ± cyclophosphamide 2 mg/kg/d PO for 3-6 mo followed by high dose MTX (20-25 mg PO/SC weekly) or azathioprine (2 mg/kg/d PO OD)
- consider biologic agents (rituximab, IVIg) and plasmapheresis (PEXIVAS trial)
- RAVE trial (NEJM 2010;363:221-232): rituximab equivalent or superior to cyclophosphamide in severe or relapsing disease

Medium Vessel Vasculitis

POLYARTERITIS NODOSA

Definition

- systemic, necrotizing vasculitis of medium sized vessels
- ANCA negative
- often associated with hepatitis B positivity
- incidence 0.7 per 100,000; affects individuals between 40-60 yr; M:F = 2:1

<tr>
<td>8. Hepatitis B positive</td>
<td>Presence of hepatitis B surface antigen or Ab</td>
</tr>
<tr>
<td>9. Arteriographic abnormality</td>
<td>Commonly aneurysms</td>
</tr>
<tr>
<td>10. Biopsy of artery</td>
<td>Presence of granulocytes and/or mononuclear leukocytes in the artery wall</td>
</tr>
</tbody>
</table>

*Diagnosed if 3 or more of the above 10 criteria present.
American College of Rheumatology, 1990
Etiology and Pathophysiology
• focal panmural necrotizing inflammatory lesions in small and medium-sized arteries
• thrombosis, aneurysm, or dilatation at lesion site may occur
• healed lesions show proliferation of fibrous tissue and endothelial cells that may lead to luminal occlusion

Investigations
• blood work: CBC, ESR, Cr, BUN, p-ANCA, hepatitis B serology
• imaging: angiography
• arterial biopsy

Treatment
• prednisone 1 mg/kg/d PO and cyclophosphamide 2 mg/kg/d PO
• ± anti-viral therapy to enhance clearance of hepatitis B virus

Large Vessel Vasculitis

• see Neurology, N44 and Ophthalmology, OP38 for more details

GCA/TEMPORAL ARTERITIS

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Age at onset ≥50</td>
<td></td>
</tr>
<tr>
<td>2. New headache</td>
<td>Often temporal</td>
</tr>
<tr>
<td>3. Temporal artery abnormality</td>
<td>Temporal artery tenderness or decreased pulsations, not due to arteriosclerosis</td>
</tr>
<tr>
<td>4. Elevated ESR</td>
<td>ESR ≥50 mm/h</td>
</tr>
<tr>
<td>5. Abnormal artery biopsy</td>
<td>Mononuclear cell infiltration or granulomatous inflammation, usually with multinucleated giant cells</td>
</tr>
</tbody>
</table>

*Diagnosed if 3 or more of the above 5 criteria present
American College of Rheumatology, 1990

Epidemiology
• most frequent vasculitis in North America
• patients >50 yr
• F:M = 2:1
• North-South gradient (predominance in Northern Europe/US)
• affects extracranial arteries

Signs and Symptoms
• new onset temporal headache ± scalp tenderness due to inflammation of involved portion of the temporal or occipital arteries
• sudden, painless loss of vision and/or diplopia due to narrowing of the ophthalmic or posterior ciliary arteries (PCA more common); can affect both eyes
• tongue and jaw claudication (pain in muscles of mastication on prolonged chewing)
• PMR (proximal myalgia, constitutional symptoms, elevated ESR) occurs in 30% of patients
• aortic arch syndrome (involvement of subclavian and brachial branches of aorta result in pulseless disease), aortic aneurysm ± rupture are late complications

Investigations
• diagnosis made by clinical suspicion, increased ESR, increased CRP, temporal artery biopsy within 14 d of starting steroids, possible U/S

Treatment
• if suspect GCA, immediately start high dose prednisone 1 mg/kg in divided doses for approximately 4 wk, and then tapering prednisone as symptoms resolve; highly effective in treatment and in prevention of blindness and other vascular complications
• consider low dose ASA

Prognosis
• increased risk of thoracic aortic aneurysm and aortic dissection
• yearly CXR ± abdominal U/S as screening

Ankylosing Spondylitis

Definition
- chronic inflammatory arthritis involving the sacroiliac joints and vertebrae
- AS in women: more peripheral arthritis and upper spine spondylitis
- prototype of the spondyloarthropathies

Table 26. ASAS Classification Criteria for Axial Spondyloarthritis*

| Sacroiliitis on imaging plus ≥1 AS feature or HLA-B27 positive plus ≥2 AS features |
|-------------------------------------|-------------------------------------|
| AS features:                        | Sacroiliitis on imaging:             |
| • Inflammatory back pain            | • Active (acute) inflammation on MRI highly suggestive of sacroiliitis associated with AS |
| • Arthritis                         | • Definite radiographic sacroiliitis ≥ grade 2 bilaterally or grade 3-4 unilaterally |
| • Enthesitis (heel)                 |                                       |
| • Uveitis                           |                                       |
| • Dactylitis                        |                                       |
| • Psoriasis                         |                                       |
| • Crohn’s disease/colitis           |                                       |
| • Good response to NSAIDs           |                                       |
| • Family history of AS              |                                       |
| • HLA-B27 positive                  |                                       |
| • Elevated CRP                      |                                       |

*For patients with ≥3 mo back pain and age at onset ≤45 yr

Etiology and Pathophysiology
- enthesitis (inflammation of tendon or ligament at site of attachment to bone)
- inflammation → osteopenia → erosion → ossification → osteoproliferation (syndesmophytes)

Epidemiology
- M:F = 5:1; females have milder disease which may be under-recognized
- 95% of patients have HLA-B27 (9% HLA-B27 positive in general population)
Table 27. Types of Back Pain

<td>+</td>
<td>–</td>
</tr>
</tbody>
</table>

Signs and Symptoms

- **axial**
  - Mid and lower back stiffness, prolonged morning stiffness, night pain, persistent buttock pain, painful sacroiliac joint (+ Faber test)
  - Spinal restriction (decreased ROM): lumbar (decreased Schober), thoracic (decreased chest wall expansion, normal >5 cm at T4), cervical (global decrease, often extension first)
  - Postural changes: decreased lumbar lordosis + increased thoracic kyphosis + increased cervical flexion = increased occiput to wall distance (>5 cm)

- **peripheral**
  - Asymmetrical large joint arthritis, most often involving lower limb
  - Enthesitis: tenderness over tendon insertion, or Achilles tendon and plantar fascia insertions into the calcaneus

- **extra-articular manifestations**
  - Ophthalmic: acute anterior uveitis is common (25-30% patients)
  - Renal: amyloidosis (late and rare) and IgA nephropathy
  - Gastrointestinal: IBD
  - Cardiac: aortitis, aortic regurgitation, pericarditis, conduction disturbances, heart failure (rare)
  - Respiratory: apical fibrosis (rare)
  - Neurologic: cauda equina syndrome (rare)
  - Skin: psoriasis

Investigations

- X-ray of SI joint: “pseudowidening” of joint due to erosion with joint sclerosis → bony fusion (late), symmetric sacroiliitis
- X-ray of spine: “squaring of edges” from erosion and sclerosis on corners of vertebral bodies (shiny corner sign) leading to ossification of outer fibers of annulus fibrosis (bridging syndesmophytes) → “bamboo spine” radiographically
- MRI of spine: assess activity in early disease; detection of cartilage changes, bone marrow edema, bone erosions, and subchondral bone changes. Best seen on T2 STIR images (suppress fat and see bone edema)

Treatment

- **conservative/non-pharmacologic**
  - Prevent fusion from poor posture and disability through: exercise (e.g. swimming), postural and deep breathing exercises, outpatient PT, smoking cessation
- **medical**
  - NSAIDs (first line of treatment)
  - Glucocorticoids (topical eye drops, local injections)
  - DMARDs for peripheral arthritis (sulfasalazine, MTX)
  - Biologics for axial and peripheral involvement
  - Manage extra-articular manifestations
- **surgical**
  - Hip replacement, vertebral ostectomy for marked deformity

Prognosis

- Spontaneous remissions and relapses are common and can occur at any age
- Function may be excellent despite spinal deformity
- Favorable prognosis if female and age of onset >40 yr
- Early onset with hip disease may lead to severe disability; may require arthroplasty
Enteropathic Arthritis

- see Gastroenterology, Inflammatory Bowel Disease, G19
- MSK manifestations in the setting of either ulcerative colitis or Crohn’s disease include peripheral arthritis (large joint, asymmetrical), spondylitis, and hypertrophic osteoarthropathy
- non-arthritic MSK manifestations can occur 2º to steroid treatment of bowel inflammation (arthralgia, myalgia, osteoporosis, AVN)
- NSAIDs should be used cautiously as they may exacerbate bowel disease

| Table 28. Comparing Features of Spondylitis vs. Peripheral Arthritis in EA |
|-----------------------------|-----------------------------|
| Parameter                  | Spondylitis | Peripheral Arthritis |
| HLA-B27 Association        | Yes          | No                     |
| Gender                     | M>F          | M=F                    |
| Onset Before IBD           | Yes          | No                     |
| Parallels IBD Course       | No           | Yes                    |
| Type of IBD                | UC=CD        | CD                     |

Psoriatic Arthritis

Etiology and Pathophysiology
- unclear but many genetic, immunologic, and some environmental factors involved (e.g. psoriatic plaque flora, particularly Group A Streptococcus, and trauma)

Epidemiology
- psoriasis affects 1% of population
- arthropathy in 10% of patients with psoriasis
- 15-20% of patients will develop joint disease before skin lesions appear

Signs and Symptoms
- dermatologic
  - well-demarcated erythematous plaques with silvery scale
  - nail involvement: pitting, transverse or longitudinal ridging, discoloration, subungual hyperkeratosis, onycholysis, and oil drops
- musculoskeletal
  - 5 general patterns
    - asymmetric oligoarthritis (most common – 70%)
    - arthritis of DIP joints with nail changes
    - destructive (mutlans) arthritis (5%)
    - symmetric polyarthritis (similar to RA)
    - sacroiliitis and spondylitis (usually older, male patients)
- other findings: dactylitis, enthesopathy
- ophthalmic
  - conjunctivitis, iritis (anterior uveitis)
- cardiac and respiratory (late findings)
  - aortic insufficiency
  - apical lung fibrosis
- neurologic
  - cauda equina syndrome
- radiologic
  - floating syndesmophytes
  - pencil-in-cup appearance at IP joints
  - osteolysis, periostitis

Treatment
- treat skin lesions (e.g. steroid cream, salicylic and/or retinoic acid, tar, UV light)
- NSAIDs or IA steroids
- DMARDs, biologic therapies to minimize erosive disease (use early if peripheral joint involvement)

*To meet the CASPAR (Classification criteria for Psoriatic Arthritis) criteria, a patient must have inflammatory arthritic disease (joint, spine, or enthesis) with ≥3 points from the above 5 categories

Arthritis Rheum 2006;54(8):2665-2673. Classification criteria for psoriatic arthritis: development
**Reactive Arthritis**

**Definition**
- two meanings
  1. ReA: a sterile arthritis following an infection (e.g. rheumatic fever, post-viral arthritis, etc.), not used frequently by rheumatologists
  2. ReA: one of the seronegative spondyloarthropathies in which patients have a peripheral arthritis (≥1 mo duration) accompanied by one or more extra-articular manifestations that appears shortly after certain infections of the GI or GU tracts

**Etiology**
- onset following an infectious episode either involving the GI or GU tract
  - GI: *Shigella*, *Salmonella*, *Campylobacter*, *Yersinia* species
  - GU: *Chlamydia* (isolated in 16-44% of ReA cases), *Mycoplasma* species
- acute clinical course
  - 1-4 wk post-infection
  - lasts weeks to years
  - often recurring
  - spinal involvement persists

**Epidemiology**
- in HLA-B27 patients, axial > peripheral involvement
- M>F

**Signs and Symptoms**
- **musculoskeletal**
  - peripheral arthritis, asymmetric pattern, spondylitis, Achilles tendinitis, plantar fasciitis, dactylitis
- **ophthalmic**
  - iritis (anterior uveitis), conjunctivitis
- **dermatologic**
  - keratoderma blenorrhagicum (hyperkeratotic skin lesions on palms and soles) and balanitis circinata (small, shallow, painless ulcers of glans penis and urethral meatus) are diagnostic
- **gastrointestinal**
  - oral ulcers, diarrhea
- **urethritis and cervicitis**
  - sterile cultures; presence not related to site of initiating infection

**Investigations**
- diagnosis is clinical plus laboratory
- blood work: normocytic, normochromic anemia, and leukocytosis
- sterile cultures
- serology: HLA-B27 positive

**Treatment**
- antibiotics for non-articular infections
- NSAIDs, physical therapy, exercise
- local therapy
  - joint protection
  - IA steroid injection
  - topical steroid for ocular involvement
- systemic therapy
  - corticosteroids, sulfasalazine, MTX (for peripheral joint involvement only)
  - TNF-α inhibitors for spinal inflammation

**Prognosis**
- self-limited, typically 3-5 mo, varies based on pathogen and patient’s genetic background
- chronic in 15-20% of cases

---

**Crystal-Induced Arthropathies**

Gout

Definition
- derangement in purine metabolism resulting in hyperuricemia; monosodium urate crystal deposits in tissues (tophi) and synovium (microtophi)

Etiology and Pathogenesis
- sources of uric acid: diet and endogenous
  - hypoxanthine \( \rightarrow \) xanthine \( \rightarrow \) uric acid
  - both steps catalyzed by xanthine oxidase
- primary or genetic
  - mostly due to idiopathic renal underexcretion (90%)
  - also idiopathic overproduction or abnormal enzyme production/function
- secondary
  - dietary excess (particularly high consumption of beer, seafood, and meat)
  - underexcretion (>90%): renal failure, drugs, systemic conditions
  - overproduction (<10%): increased nucleic acid turnover states (e.g. malignancy, post-chemotherapy)
- sudden changes (increasing or decreasing) in uric acid concentration are more important than absolute values
  - acute gout can occur with normal serum uric acid
  - changes in pH, temperature, or initiation of antihyperuricemics may precipitate an acute gouty attack
- common precipitants: alcohol, dietary excess, dehydration, drugs (e.g. thiazide and loop diuretics), trauma, illness, surgery, starting xanthine oxidase inhibitor therapy
- other associated conditions: HTN, obesity, DM, starvation

Epidemiology
- most common in males >45 yr old
- extremely rare in premenopausal females

Signs and Symptoms
- single episode progressing to recurrent episodes of acute inflammatory arthritis
- acute gouty arthritis
  - severe pain, redness, joint swelling, usually involving lower extremities
  - joint mobility may be limited
  - attack will subside spontaneously within several days to weeks; may recur
- tophi
  - urate deposits on cartilage, tendons, bursae, soft tissues, and synovial membranes
  - common sites: first MTP, ear helix, olecranon bursae, tendon insertions (common in Achilles tendon)
- kidney
  - gouty nephropathy
  - uric acid calculi

Investigations
- joint aspirate: >90% of joint aspirates show crystals of monosodium urate (see Table 30)
- x-rays may show tophi as soft tissue swelling, punched-out lesions – erosion with “over-hanging” edge

Treatment
- acute gout
  - NSAIDs: high dose, then taper as symptoms improve
  - corticosteroids: IA, oral, or intra-muscular (if renal, cardiovascular, or GI disease and/or if NSAIDs contraindicated or failed)
  - colchicine within first 12 h but effectiveness limited by narrow therapeutic range
  - allopurinol can worsen an acute attack (do not start during acute flare)
- chronic gout
  - conservative
    - avoid foods with high purine content (e.g. visceral meats, sardines, shellfish, beans, peas)
    - avoid drugs with hyperuricemic effects (e.g. pyrazinamide, ethambutol, thiazide, alcohol)
medical
- antihyperuricemic drugs (allopurinol and febuxostat): decrease uric acid production by inhibiting xanthine oxidase
- uricosuric drugs (probenecid, sulfinpyrazone): use if failure on or intolerant to allopurinol; do not use in renal failure
- prophylaxis prior to starting antihyperuricemic drugs (colchicine/low-dose NSAID)
- in renal disease secondary to hyperuricemia, use low-dose allopurinol and monitor Cr
- indications for treatment with antihyperuricemic medications include:
  - recurrent attacks, tophi, bone erosions, urate kidney stones
  - perhaps in renal dysfunction with very high urate load (controversial)

Pseudogout (Calcium Pyrophosphate Dihydrate Disease)

Etiology and Pathophysiology
- acute inflammatory arthritis due to phagocytosis of IgG-coated CPPD crystals by neutrophils and subsequent release of inflammatory mediators within joint space
- more frequently polyarticular
- slower in onset in comparison to gout, lasts up to 3 wk but is self-limited

Risk Factors
- old age, advanced OA, neuropathic joints
- other associated conditions: hyperparathyroidism, hypothyroidism, hypomagnesemia, hypophosphatasia (low ALP), DM, hemochromatosis

Signs and Symptoms
- affects knees, wrists, MCPs, hips, shoulders, elbows, ankles, big toe
- multiple manifestations
  - asymptomatic crystal deposition (seen on radiograph only)
  - acute crystal arthritis (self-limited flares of acute inflammatory arthritis resembling gout)
  - pseudo-OA (progressive joint degeneration, sometimes with episodes of acute inflammatory arthritis)
  - pseudo-RA (symmetrical polyarticular pattern with morning stiffness and constitutional symptoms)
- acute may be triggered by dehydration, acute illness, surgery, trauma

Investigations
- must aspirate joint to rule out septic arthritis, gout
- CPPD crystals: present in 60% of patients, often only a few crystals
- x-rays show chondrocalcinosis in 75%: radiodensities in fibrocartilaginous structures (e.g. knee menisci) or linear radiodensities in hyaline articular cartilage

Treatment
- joint aspiration, rest, and protection
- NSAIDs: also used for maintenance therapy
- prophylactic colchicine PO (controversial)
- IA or oral steroids to relieve inflammation

Pediatric Rheumatology
- see Pediatrics, P93

Non-Articular Rheumatism

Definition
- disorders that primarily affect soft tissues or periarticular structures
- includes bursitis, tendinitis, tenosynovitis, fibromyalgia, and PMR

Polymyalgia Rheumatica

Definition
- characterized by pain and stiffness of the proximal extremities (girdle area)
- closely related to GCA (15% of patients with PMR develop GCA)
- no muscle weakness
Table 31. PMR Classification Criteria Scoring Algorithm*

<table>
<thead>

</tr>
<tr>
<td>Both shoulders with subdeltoid bursitis, biceps tenosynovitis, or gleno-humeral synovitis on U/S</td>
<td>N/A</td>
</tr>
</tbody>
</table>

*Required criteria: age ≥50 yr, bilateral shoulder aching, and abnormal ESR/CRP
**A score of 4 or more is categorized as PMR in the algorithm without U/S and a score of 5 or more is categorized as PMR in the algorithm with U/S

Epidemiology
- incidence 50 per 100,000 per year in those >50 yr
- age of onset typically >50, F:M = 2:1

Signs and Symptoms
- constitutional symptoms prominent (fever, weight loss, malaise)
- pain and stiffness of symmetrical proximal muscles (neck, shoulder and hip girdles, thighs)
- gel phenomenon (stiffness after prolonged inactivity)
- physical exam reveals tender muscles, but no weakness or atrophy

Investigations
- blood work: often shows anemia, elevated platelets, elevated ESR and CRP, and normal CK; up to 5% of PMR reported with normal inflammatory markers

Treatment
- goal of therapy: symptom relief
- start with prednisone dose of 15-20 mg PO OD
- taper slowly over 2 yr period monitoring ESR and symptoms closely
- relapses should be diagnosed and treated on clinical basis; do not treat a rise in ESR as a relapse
- treat relapses aggressively (50% relapse rate)
- monitor for steroid side effects, glucocorticoid-induced osteoporosis prevention, and follow for symptoms of GCA

Fibromyalgia

Definition
- chronic (>3 mo), widespread (axial, left- and right-sided, upper and lower segment), non-articular pain with characteristic tender points

Diagnosis
2010 Diagnostic Criteria for Fibromyalgia
1. widespread pain index ≥7 and symptom severity score ≥5 or WPI 3-6 and SS ≥9
2. symptoms have been present at a similar level for ≥3 mo
3. the patient does not have a disorder that would otherwise explain the pain

- widespread pain index = number of areas in which the patient had pain over the last week (L and R: shoulder girdle, upper arm, lower arm, hip, upper leg, lower leg, jaw, chest, abdomen, upper and lower back, neck = max score 19)
- symptom severity score = sum of a) severity of fatigue, b) waking unrefreshed, and c) cognitive symptoms over the past week, plus d) extent of somatic symptoms (IBS, H/A, Abdominal pain/ cramps, dry mouth, fever, hives, ringing in ears, vomiting, heartburn, dry eyes, SOB, loss of appetite, rash, hair loss, easy bruising, etc.); all (a-d) rated on 0-3 scale:
  - 0 = no problem, 1 = mild, 2 = moderate, 3 = severe
- this clinical definition identified 88.1% of American College of Rheumatology classified fibromyalgia and can allow longitudinal assessment of symptom severity

Epidemiology
- F:M = 3:1
- primarily ages 25-45 yr, some adolescents
- prevalence of 2-5% in general population
- overlaps with chronic fatigue syndrome and myofascial pain syndrome
- strong association with psychiatric illness
Signs and Symptoms
- widespread aching, stiffness
- easy fatigability
- sleep disturbance: non-restorative sleep, difficulty falling asleep, and frequent waking
- symptoms aggravated by physical activity, poor sleep, emotional stress
- patient feels that joints are diffusely swollen although joint examination is normal
- neurologic symptoms of hyperalgesia, paresthesias
- associated with irritable bowel or bladder syndrome, migraines, tension headaches, restless legs syndrome, obesity, depression, and anxiety
- physical exam should reveal only tenderness with palpation of soft tissues, with no specificity for trigger/tender points

Investigations
- blood work: includes TSH and ESR; all typically normal unless unrelated, underlying illness present
- serology: do not order ANA or RF unless there is clinical suspicion for a connective tissue disease
- laboratory sleep assessment

Differential Diagnosis
- diagnosis of exclusion
- rule out other disorders by history and physical exam

Treatment
- conservative
  - education
  - exercise program (walking, aquatic exercises), physical therapy (good posture, stretching, muscle strengthening, massage)
  - stress reduction, CBT
  - no evidence for alternative medicine such as biofeedback, meditation, acupuncture
- medical
  - low dose tricyclic antidepressant (e.g. amitriptyline)
    - for sleep restoration
  - select those with lower anticholinergic side effects
  - SNRI: duloxetine, milnacipran
  - anticonvulsant: pregabalin, gabapentin
  - analgesics may be beneficial for pain that interferes with sleep (NSAIDs, not narcotics)

Prognosis
- variable; usually chronic, unless diagnosed and treated early

Adult Onset Still’s Disease

Definition
- systemic inflammatory condition (ANA and RF negative) with fevers and characteristic rash, numerous systemic symptoms, and may have severe arthritis

Etiology and Pathophysiology
- idiopathic; infectious triggers likely – various viruses and bacteria have been implicated
- stress increases risk

Epidemiology
- F:M; age of onset typically 16-40, approximately 1 per 100,000

Signs and Symptoms
- classic triad of symptoms
  - high-spiking fevers (95.7% of patients, typically T = 102.2°F/39°C, <4 h duration, quotidian pattern)
  - characteristic “salmon rash” (~72% of patients, on proximal limbs + trunk)
  - arthralgia/arthritis (64-100%)
  - sore throat, myalgias and serositis may also occur
  - arthritis is symmetric, typically affects large joints, i.e. wrists, knees and ankles, may involve PIP and DIPs, elbow, MTPs
  - liver abnormalities ± hepatomegaly (50-75% patients)
  - splenomegaly (44%)
Classification
• numerous classification systems proposed
• Yamaguchi’s criteria (J Rheumatol 1992;19:424-30): need 5 criteria to diagnose Still’s, at least 2 major
  ▪ major criteria
    • T >39°C, intermittent, >1 wk
    • typical rash
    • WBC >10,000 (>80% granulocytes)
  ▪ minor criteria
    • sore throat
    • lymphadenopathy ± splenomegaly
    • abnormal transaminases
    • negative ANA and RF
• exclusion criteria: infection, malignancy, rheumatic disease

Investigations
• ANA and RF negative
• markedly elevated ESR, CRP, ferritin (typically >1000 ng/mL, >2200 pmol/L)
  ▪ total ferritin >5x ULN = 80% sensitive, 41% specific
• anemia, thrombocytosis, leukocytosis may occur
• transaminases, LDH may be elevated

Treatment
• refer to rheumatologist for treatment with biologics (anti-IL1 and anti-IL6 agents)
• begin management with low-dose glucocorticoids ± MTX

Basic Anatomy Review

- recall that the anatomical position of the penis is erect; therefore, the anatomical ventral side of the penis appears to be the dorsal side of the flaccid penis

Figure 1. Midline cross-section of abdominal wall

Figure 2. Anatomy of scrotum

Figure 3. Essential genitourinary tract male anatomy
Urologic History

- follow the OPQRSTUVW approach
  - note that pain may not be limited to the genital region (e.g. lower abdomen, CVA)
- inquire about risk factors: past urologic disease (e.g. UTI, stones, STD, cancers, anatomic abnormalities, family Hx, medications, lifestyle factors, trauma, previous surgical procedures)
- urinary habits
  - frequency of voiding, quality of urine, volume of voids, incontinence, nocturia
  - specific urinary symptoms include
    - storage symptoms: frequency, nocturia, urgency
    - voiding symptoms: straining, hesitancy, dysuria, intermittency, post-void dribbling, reduced stream, feeling of incomplete voiding
    - hematuria: part of stream during which bleeding occurs, blood clots
    - incontinence: rushing to washroom (urge); leakage with coughing, sneezing, laughing (stress); constant dribbling (overflow)
- sexual function
  - scrotal mass: see Scrotal Mass, U28
  - ED: see Erectile Dysfunction, U30
  - infertility: see Infertility, U33
- risk factors
  - past urologic disease (e.g. UTI, stones, cancers, STD), anatomic abnormalities, trauma, previous surgical procedures, medications, family Hx, lifestyle factors
- associated symptoms
  - N/V
  - bowel dysfunction
- constitutional symptoms
  - fever, chills, unintentional weight loss, night sweats, fatigue, malaise

Always ask about sexual function on history. Change in erectile function can be one of the first symptoms that there is concomitant vascular disease. If there is new onset ED, consider screening for diabetes and CAD risk factors.
Hematuria (Blood in the Urine)

Macroscopic (Gross) Hematuria

Definition
- blood in the urine that can be seen with the naked eye

Classification
- see Nephrology, NP21

History
- inquire about timing of hematuria in urinary stream
  - initial: anterior urethra
  - terminal: bladder neck and prostatic urethra
  - total: bladder and/or above

Investigations
- CBC (r/o anemia, leukocytosis), electrolytes, Cr, BUN, INR, PTT
- urine studies
  - U/A, C&S, cytology
- imaging
  - CT (with contrast) has largely replaced IVP to investigate upper tracts
    - consider contraindications to contrast; allergy, renal insufficiency
  - U/S alone is not sufficient
  - cystoscopy to investigate lower tract (possible retrograde pyelogram)

Acute Management of Severe Bladder Hemorrhage
- manual irrigation via catheter with normal saline to remove clots
- CBI using large (22-26 Fr) 3-way Foley to help prevent clot formation
- cystoscopy if active bleeding
  - identify resectable tumors
  - coagulate obvious sites of bleeding
- refractory bleeding
  - intravesical agents
    - continuous intravesical irrigation with 1% aluminum potassium sulfate solution as needed
    - intravesical instillation of 1% silver nitrate solution
    - intravesical instillation of 1-4% formalin (requires GA and pre-procedure cystogram to rule out reflux)
    - embolization or ligation of iliac arteries
    - cystectomy and diversion (rarely performed)

Common Urologic Causes of Hematuria
Can Be Classified as:
- TICS
  - Trauma/Tumor/Toxins
  - Infection/Inflammatory
  - Calculi/Cysts
  - Surgery/Sickle cell and other hematological causes

Upper Tract Imaging Options
- Intravenous Pyelogram (IVP)
  - Traditional option but rarely used (replaced by CTU), reasonable sensitivity for UCC, but poor sensitivity for RCC
- U/S: Superior to IVP for evaluation of renal parenchyma and renal cysts. Limited sensitivity for UCC and small renal masses. U/S alone is not sufficient for upper tract imaging
- CT Urography (CTU): Optimal test for renal parenchyma, calculi, and infections. Involves exposure to radiation and IV contrast. Assess kidney function, allergies prior to use of contrast

Gross, painless hematuria in adults is bladder cancer until proven otherwise
Microscopic Hematuria

Definition
- blood in the urine that is not visible to the naked eye
- > 3 RBCs/HPF on urinalysis of at least two separate samples

Figure 6. Workup of asymptomatic microscopic hematuria
Based on CUA Guidelines. Alternatively, the AUA recommends cystoscopy and CT urogram for all patients with confirmed microscopic hematuria; follow-up for negative workup is urinalysis yearly for two years, with repeat anatomic evaluation if microscopic hematuria persists

Voiding Dysfunction
- see Gynecology, GY34 for relevant female topics

Voiding
- two phases of lower urinary tract function
  1. storage phase (bladder filling and urine storage)
     • accommodation and compliance
     • no involuntary contraction
  2. voiding phase (bladder emptying)
     • coordinated detrusor contraction
     • synchronous relaxation of outlet sphincters
     • no anatomic obstruction
- voiding dysfunction can therefore be classified as
  • failure to store: due to bladder or outlet
  • failure to void: due to bladder or outlet
- three types of symptoms
  • storage (formerly known as irritative)
  • voiding (formerly known as obstructive)
  • post-voiding

Urinary Incontinence

Definition
- involuntary leakage of urine

Etiology
- urgency incontinence
  • detrusor overactivity
    • CNS lesion, inflammation/infection (cystitis, stone, tumor), bladder neck obstruction (tumor, stone), BPH, idiopathic

- decreased compliance of bladder wall (inability to store urine)
  - CNS lesion, fibrosis
  - sphincter/urethral problem
- stress urinary incontinence (SUI)
  - common in women; seen in men after prostate cancer treatment or pelvic operations
  - urethral hypermobility
    - weakened pelvic floor and musculofascial urethral and vaginal supporting mechanisms allows bladder neck and urethra to descend with increased intra-abdominal pressure
    - urethra is pulled open by greater motion of posterior wall of outlet relative to anterior wall
    - associated with childbirth, pelvic surgery, aging, levator muscle weakness, obesity
  - intrinsic sphincter deficiency (ISD): weakness of the urethra and associated smooth and striated muscle elements
  - pelvic surgery, neurologic problem, aging and hypoestrogen state
  - ISD and urethral hypermobility can co-exist
- mixed incontinence
  - combination of stress and urgency incontinence
- overflow incontinence
  - is a term sometimes used to describe urinary incontinence as a complication of urinary retention; for causes of urinary retention see Table 4
  - use of the term is used it should be accompanied by the associated pathophysiology (e.g. BPH with overflow incontinence)

**Epidemiology**
- variable prevalence in women: 25-45%
- F:M = 2:1
- more frequent in the elderly, affecting 5-15% of those living in the community and 50% of nursing home residents

</tbody>
</table>

**Clinical Features**
- suprapubic pain
- palpable and/or percussible bladder (suprapubic)
- possible purulent/bloody meatal D/C
- increased size of prostate or reduced anal sphincter tone on DRE
- neurological: presence of abnormal or absent deep tendon reflexes, reduced “anal wink”, saddle anesthesia

**Causes of Reversible Urinary Incontinence**
- DIAPERS
  - Delirium
  - Inflammation/Infection
  - Atrophic vaginitis/urethritis
  - Psychiatric/psychological
  - Excess U/O
  - Restricted mobility/Retention
  - Stool impaction

**Urgency is the symptom of a strong need to void; it is not necessarily associated with incontinence**

**Acute vs. Chronic Retention**
- Acute retention is a medical emergency characterized by suprapubic pain and anuria with normal bladder volume and architecture
- Chronic retention can be painless with greatly increased bladder volume and detrusor hypertrophy followed by atony (late)

If a trauma patient is unable to void, has blood at urethral meatus, a scrotal hematoma, or a high riding prostate, there is urethral injury until proven otherwise so catheterization is CONTRAINDICATED unless performed by urology staff or resident
Investigations
- CBC, electrolytes, Cr, BUN, U/A and urine C&S, U/S, cystoscopy, urodynamic studies, PVR

Treatment
- treat underlying cause
- catheterization
  - acute retention
    - immediate catheterization to relieve retention; leave Foley in to drain bladder; follow-up to determine cause; closely monitor fluid status and electrolytes (risk of POD)
  - chronic retention
    - intermittent catheterization by patient may be used; definitive treatment depends on etiology
  - suprapubic tube placement
  - for post-operative patients with retention:
    - encourage ambulation
    - α-blockers to relax bladder neck outlet
    - may need catheterization
    - definitive treatment will depend on etiology

Benign Prostatic Hyperplasia

Definition
- periurethral hyperplasia of stroma and epithelium in prostatic transition zone
- prostatic smooth muscle cells play a role in addition to hyperplasia

Etiology
- etiology unknown
  - DHT required (converted from testosterone by 5-α reductase)
  - possible role of impaired apoptosis, estrogens, other growth factors
  - genetic: increased risk in 1st degree relatives and twin studies

Epidemiology
- age-related, extremely common (50% of 50 yr olds, 80% of 80 yr olds)
- 25% of men will require treatment

Clinical Features
- result from outlet obstruction and compensatory changes in detrusor function
- voiding and storage symptoms
- DRE
  - prostate is smooth, rubbery, and symmetrically enlarged
- complications
  - retention
  - overflow incontinence
  - hydronephrosis
  - renal insufficiency
  - infection
  - gross hematuria
  - bladder stones

Investigations
- Hx, assessing LUTS and impact on QOL
  - may include self-administered questionnaires (IPSS or AUA symptom index for severity, progression, and treatment response)
  - P/E, including DRE
  - U/A to exclude UTI
  - Cr to assess renal function
  - uroflowmetry to measure flow rate (optional)
  - PVR (optional)
  - consider cystoscopy or transrectal ultrasound prior to potential surgical management to evaluate outlet and prostate volume
  - biopsy if suspicious for malignancy, i.e., elevated PSA or abnormal DRE

AUA BPH Symptom Score
FUNWISE
- Frequency
- Urgency
- Nocturia
- Weak stream
- Intermittency
- Straining
- Emptying, incomplete feeling of
  - Each symptom graded out of 5
  - 0-7: Mildly symptomatic
  - 8-19: Moderately symptomatic
  - 20-35: Severely symptomatic
  - Note: dysuria not included in score but is commonly associated with BPH

Approximate Prostate Sizes
- • 20 cc – chestnut
- • 25 cc – plum
- • 50 cc – lemon
- • 75 cc – orange
- • 100 cc – grapefruit

Figure 7. Cross-section of prostate

Patients with ascites may have a falsely elevated PVR measured by bladder scan

Prostate size does not correlate well with symptoms in BPH

Urethral Stricture

Definition
- decrease in urethral calibre due to scar formation in urethra (may also involve corpus spongiosum)
- M>F

Etiology
- congenital
  - failure of normal canalization (i.e. posterior urethral valves)
- trauma
  - instrumentation/catheterization (most common)
  - external trauma (e.g. burns, straddle injury)
  - foreign body
- infection
  - long-term indwelling catheter
- STD (gonococcal or chlamydial disease)
- inflammation
  - balanitis xerotica obliterans (BXO; lichen sclerosis or chronic progressive sclerosing dermatosis of the male genitalia) causing meatal and urethral stenosis

Clinical Features
- voiding symptoms
- urinary retention
- hydronephrosis
- related infections: recurrent UTI, secondary prostatitis/epididymitis

Investigations
- laboratory findings
  - flow rates <10 mL/s (normal ~20 mL/s) on uroflowmetry
  - urine culture usually negative, but U/A may show pyuria
- radiologic findings
  - RUG and VCUG will demonstrate location
- cystoscopy

Treatment
- urethral dilatation
  - temporarily increases lumen size by breaking up scar tissue
  - healing will often reform scar tissue, recurrence of stricture
- visual internal urethrotomy (VIU)
  - endoscopically incise stricture
  - equal success rates to dilation with mid bulbar strictures <2 cm
  - high rate of recurrence (30-80%), avoid in younger patients
- open surgical reconstruction
  - complete stricture excision with anastomosis, ± urethroplasty depending on location and size of stricture

Men with planned cataract surgery should avoid starting α-adrenergic antagonists until after their surgery due to the risk of intraoperative floppy iris syndrome.

BPH Surgery Absolute Indication
- Renal failure with obstructive uropathy
- Refractory urinary retention

Relative Indications
- Recurrent UTIs
- Recurrent hematuria refractory to medical treatment
- Renal insufficiency (r/o other causes)
- Bladder stones

Finasteride for Benign Prostatic Hyperplasia
Cochrane DB Syst Rev 2010;10:CD0060175

Purpose: To examine the effectiveness and safety of finasteride vs. placebo or other active controls for the treatment of urinary tract symptoms.

Summary of Findings:
1. Finasteride improved urinary symptoms more than placebo in trials >1 yr duration and significantly lowered the risk of BPH progression.
2. Compared with alpha blockers, finasteride was less effective than either doxazosin or terazosin, but equally effective as tamsulosin.
3. Symptom improvement with finasteride + doxazosin is equal to doxazosin alone.
4. Finasteride treatment resulted in an increased risk of ejaculation disorder, impotence and lowered libido compared with placebo.
5. Compared with doxazosin and terazosin, finasteride had a lower risk of asthma, dizziness, and postural hypotension.

MicroWave TherapY for benign prostaTic Hyperplasia
Cochrane DB Syst Rev 2012;10:CD004135

Purpose: To evaluate the efficacy and safety of microwave thermotherapy for the treatment of benign prostatic obstruction.

Selection Criteria: RCTs evaluating transurethral microwave therapy (TUMT) for men with symptomatic BPH with multiple comparison groups.

Results/Conclusions: 15 studies, 1,585 patients, mean age 66.8 yr, 3-60 mo duration. Mean urinary symptom scores decreased by 65% with TUMT and 77% with TURP. The pooled mean peak urinary flow increased by 70% with TUMT and 119% with TURP. Compared with TURP, TUMT was associated with increased risks for retrograde ejaculation, treatment for strictures, hematuria, blood transfusions and transurethral resection syndrome, but increased risk for dysuria, urinary retention and rehospitalization for BPH symptoms. Overall, microwave thermotherapy techniques are effective alternatives to TURP and α blockers for treating symptomatic BPH, although less effective than TURP in improving symptom score and urinary flow.
Neurogenic Bladder

Definition
- malfunctioning urinary bladder due to deficiency in some aspect of its innervation

Neurophysiology

Table 6. Efferent Sympathetic, Parasympathetic, and Somatic Nerve Supply

<table>
<thead>
<tr>
<th>Nerve Fibers</th>
<th>Nerve Roots</th>
<th>Neurotransmitter/Receptor</th>
<th>Target</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>Parasympathetic</td>
<td>S2-4</td>
<td>ACh/Muscarinic (M2, M3)</td>
<td>Detrusor</td>
</tr>
</tbody>
</table>

- stretch receptors in the bladder wall relay information to PMC and activate micturition reflex (normally inhibited by cortical input)
  - micturition
    - stimulation of parasympathetic neurons (bladder contraction)
    - inhibition of sympathetic and somatic neurons (internal and external sphincter relaxation, respectively)
  - urine storage
    - opposite of micturition
- voluntary action of external sphincter (pudendal nerve roots S2-S4) can inhibit urge to urinate
- cerebellum, basal ganglia, thalamus, and hypothalamus all have input at PMC in the brainstem

Classification of Neurologic Voiding Dysfunction
- neuropathic detrusor overactivity (formerly termed detrusor hyperreflexia)
  - lesion above PMC (e.g. stroke, tumor, MS, Parkinson’s disease)
  - loss of voluntary inhibition of voiding
  - intact pathway inferior to PMC maintains coordination of bladder and sphincter
- detrusor sphincter dyssynergia (DSD)
  - suprasacral lesion of spinal cord (e.g. trauma, MS, arteriovenous malformation, transverse myelitis)
  - loss of coordination between detrusor and sphincter (detrusor contracts on closed sphincter and vice versa)
  - component of detrusor overactivity as well
- detrusor atony/areflexia
  - lesion of sacral cord or peripheral efferents (e.g. trauma, DM, disc herniation, MS, congenital spinal cord abnormality, post abdominoperineal resection)
  - flaccid bladder which fails to contract
  - may progress to poorly compliant bladder with high pressures
- peripheral autonomic neuropathy
  - deficient bladder sensation → increasing residual urine → decompensation (e.g. DM, neurosyphilis, herpes zoster)
- muscular lesion
  - can involve detrusor, smooth/striated sphincter

Neuro-Urologic Evaluation
- hx and P/E (urologic and general neurologic)
- U/A, renal profile
- imaging
  - U/S to r/o hydronephrosis and stones
- cystoscopy
- urodynamic studies
  - uroflowmetry to assess flow rate, pattern
  - filling CMG to assess capacity, compliance, detrusor overactivity
  - voiding CMG (pressure-flow study) to assess bladder contractility and extent of bladder outflow obstruction
  - video study to visualize bladder/bladder neck/urethra during CMG using x-ray contrast
  - EMG ascertains presence of coordinated or uncoordinated voiding, allows accurate diagnosis of DSD

Treatment
- goals of treatment
  - prevent renal failure
  - prevent infections
  - achieve social continence
• clean intermittent catheterization (CIC)
• treatment options depend on status of bladder and urethra
  • bladder hyperactivity \(\rightarrow\) anticholinergic medications to relax bladder (see *Urinary Incontinence*, U5)
    • if refractory
      – botulinum toxin injections into bladder wall
      – occasionally augmentation cystoplasty (enlarging bladder volume and improving compliance by grafting section of detubularized bowel onto the bladder)
      – occasionally urinary diversion (ileal conduit or continent diversion) in severe cases if bladder management unsuccessful
  • flaccid bladder \(\rightarrow\) CIC

**Dysuria**

**Definition**
• painful urination

**Etiology**

Table 7. Differential Diagnosis of Dysuria

<table>

<tr>
<td>Psychogenic</td>
<td>Somatization disorder, depression, stress/anxiety disorder</td>
</tr>
<tr>
<td>Other</td>
<td>Contact sensitivity, foreign body, radiation/chemical cystitis, diverticulum</td>
</tr>
</tbody>
</table>

**Investigations**
• focused Hx and P/E to determine cause (fever, d/c, conjunctivitis, CVA tenderness, back/joint pain)
  • any d/c (urethral, vaginal, cervical) should be sent for gonococcus/chlamydia testing; wet mount if vaginal d/c
  • U/A and urine C&S
  • if suspect infection, may start empiric Antibiotic treatment
  • \(\pm\) imaging of urinary tract (tumor, stones)

**Hydronephrosis**

**Definition**
• dilation of the renal pelvis and calyces caused by the impairment in antegrade urine flow

**Etiology**
• mechanical
  • congenital: see *Congenital Abnormalities*, U35
  • acquired
    • intrinsic: trauma, inflammation and bleeding, calculi, urologic neoplasms, BPH, urethral stricture, phimosis, previous urological surgery
    • extrinsic: trauma, neoplasms (uterine fibroid; colorectal, uterine, and cervical malignancies; lymphoma), aortic aneurysm, pregnancy (gravid uterus)
  • functional
    • neuropathic: neurogenic bladder, diabetic neuropathy, spinal cord disease
    • pharmacologic: anticholinergics, \(\alpha\)-adrenergic agonists
    • hormonal: pregnancy (progesterone decreases ureteral tone)

**Investigations**
• focused Hx, inquiring about pain (flank, lower abdomen, testes, labia), U/O, medication use, pregnancy, trauma, fever, Hx of UTIs, calculi, and PID and urological surgery
• CBC, electrolytes, Cr, BUN, U/A, C&S
• imaging studies (U/S is >90% sensitive and specific)
  ▪ MAG3 diuretic renogram: evaluates differential renal function and demonstrates if functional obstruction exists

**Treatment**
• hydronephrosis can be physiologic
• treatment should be guided at improving symptoms, treating infections, or improving renal function
• urgent treatment may require percutaneous nephrostomy tube or ureteral stenting to relieve pressure

---

**Post-Obstructive Diuresis**

**Definition**
• polyuria resulting from relief of severe chronic obstruction
• >3 L/24 h or >200 cc/h over each of two consecutive hours

**Pathophysiology**
• **physiologic POD** secondary to excretion of retained urea, Na⁺, and H₂O (high osmotic load) after relief of obstruction
  ▪ self-limiting; usually resolves in 48 h with PO fluids but may persist to pathologic POD
• **pathologic POD** is a Na⁺-wasting nephropathy secondary to impaired concentrating ability of the renal tubules due to
  ▪ decreased reabsorption of NaCl in the thick ascending limb and urea in the collecting tubule
  ▪ increased medullary blood flow (solute washout)
  ▪ increased flow and solute concentration in the distal nephrons

**Management**
• admit patient and closely monitor hemodynamic status and electrolytes (Na⁺ and K⁺ q6-12h and replace prn; follow Cr and BUN to baseline)
• monitor U/O q2h and ensure total fluid intake <U/O by replacing every 1 cc U/O with 0.5 cc 1/2 NS IV (PO fluids if physiologic POD)
• avoid glucose-containing fluid replacement (iatrogenic diuresis)

---

Urinary Tract Infection

- for UTIs during pregnancy, see Obstetrics, OB19

Definition
- symptoms suggestive of UTI + evidence of pyuria and bacteriuria on U/A or urine C&S
  - if asymptomatic + 100,000 CFU/mL = asymptomatic bacteriuria; only requires treatment in certain patients (e.g. pregnancy)

Classification
- uncomplicated: lower UTI in a setting of functionally and structurally normal urinary tract
- complicated: structural and/or functional abnormality, male patients, immunocompromised, diabetic, iatrogenic complication, pregnancy, pyelonephritis, catheter-associated
- recurrent: see Recurrent/Chronic Cystitis, U13

Risk Factors
- stasis and obstruction
  - residual urine due to impaired urine flow e.g. PUVs, reflux, medication, BPH, urethral stricture, cystocele, neurogenic bladder
- foreign body
  - introduce pathogen or act as nidus of infection e.g. catheter, instrumentation
- decreased resistance to organisms
  - DM, malignancy, immunosuppression, spermicide use, estrogen depletion, antimicrobial use
- other factors
  - trauma, anatomic abnormalities, female, sexual activity, fecal incontinence

Clinical Features
- storage symptoms: frequency, urgency, dysuria
- voiding symptoms: hesitancy, post-void dribbling
- other: suprapubic pain, hematuria, foul-smelling urine
- pyelonephritis – if present: typically presents with more severe symptoms (e.g. fever/chills, CVA tenderness, flank pain)

Organisms
- typical organisms
- atypical organisms
  - tuberculosis (TB)
  - Chlamydia trachomatis
  - Mycoplasma (Ureaplasma urealyticum)
  - fungi (Candida)

Indications for Investigations
- pyelonephritis
- persistence of pyuria/symptoms following adequate antibiotic therapy
- severe infection with an increase in Cr
- recurrent/persistent infections
- atypical pathogens (urea splitting organisms)
- hx of structural abnormalities/decreased flow
Investigations
- U/A, urine C&S
  - UA: leukocytes ± nitrites ± hematuria
  - C&S: midstream, catheterized, or suprapubic aspirate
- if hematuria present, retest post-treatment, if persistent need hematuria workup (see Microscopic Hematuria, U5)
- U/S, CT scan if indicated

Treatment
- see Table 8 for approach to ABx therapy
- if febrile, consider admission with IV therapy and r/o obstruction

Recurrent/Chronic Cystitis

Definition
- ≥3 UTIs/yr

Etiology
- bacterial reinfection (80%) vs. bacterial persistence (relapse)
  - bacterial reinfection
    - recurrence of infection with either 1) a different organism, 2) the same organism if cultured >2 wk following therapy, or 3) with any organism with an intermittent sterile culture
  - bacterial persistence
    - same organism cultured within 2 wk of sensitivity-based therapy

Investigations
- assess predisposing factors as described above
- investigations may include cystoscopy, U/S, CT

Treatment
- lifestyle changes (limit caffeine intake, increase fluid/H2O intake)
- ABx: continuous vs. post-coital
- post-menopausal women: consider topical or systemic estrogen therapy
- no treatment for asymptomatic bacteriuria except in pregnant women or patients undergoing urinary tract instrumentation

Interstitial Cystitis
(Painful Bladder or Bladder Pain Syndrome)

Definition
- bladder pain, chronic urgency and frequency without other reasonable causation

Classification
- non-ulcerative (more common)
- ulcerative

Etiology
- unknown
  - theories: increased epithelial permeability, autoimmune, neurogenic, defective GAG layer overlying mucosa
  - associations: severe allergies, IBS, fibromyalgia

Epidemiology
- prevalence: 20/100,000
- 90% of cases are in females
- mean age at onset is 40 yr (non-ulcerative tends to affect a younger to middle-aged population, while ulcerative tends to be seen in middle-aged to older)

Clinical Features
- pain associated with the bladder
- glomerulations (submucosal petechiae) or Hunner’s lesions (ulcers) on cystoscopic examination
- urinary urgency
- negative U/A, urine C&S, and urine cytology

Differential Diagnosis
- UTI, vaginitis, bladder tumor
- radiation/chemical cystitis
- eosinophilic/TB cystitis
- bladder calculi

Prevention of UTIs
- Maintain good hydration (try cranberry juice)
- Wipe from front to back to avoid contamination of the urethra with feces from the rectum
- Avoid feminine hygiene sprays and scented douches
- Empty bladder immediately before and after intercourse

Cystoscopic evaluation is not necessary to make a diagnosis
Treatment
• first-line: patient empowerment (diet, lifestyle, stress management), pain management
• second-line
  - oral: pentosan polysulfate sodium, amitriptyline, cimetidine, hydroxyzine
  - intravesical: dimethylsulfoxide (DMSO), heparin, lidocaine
• third-line: cystoscopy with bladder hydrodistention (traditionally diagnostic) under GA, treat Hunner's lesions if present
• fourth-line: neuromodulation, pain management
• fifth-line: cyclosporine A, intradetrusor BTX
• sixth-line: diversion w/ or w/out cystectomy, substitution cystoplasty
• surgery (last resort): augmentation cystoplasty, or urinary diversion ± cystectomy

Acute Pyelonephritis
Definition
• infection of the renal parenchyma with local and systemic manifestations
• clinical diagnosis of flank pain, fever and elevated WBC

Etiology
• ascending (usually GN bacilli) or hematogenous route (usually GP cocci)
• causative microorganisms
  - gram positives: Enterococcus faecalis, S. aureus, S. saprophyticus
  - gram negatives: E. coli (most common), Klebsiella, Proteus, Pseudomonas, Enterobacter
• common underlying causes of pyelonephritis
  - stones, strictures, prostatic obstruction, vesicoureteric reflux, neurogenic bladder, catheters, DM, sickle-cell disease, PCKD, immunosuppression, post-renal transplant, instrumentation, pregnancy

Clinical Features
• rapid onset (<24 h)
• LUTS including frequency, urgency, hematuria; NOT dysuria unless concurrent cystitis
• fever, chills, nausea, vomiting, myalgia, malaise
• CVA tenderness or exquisite flank pain

Investigations
• U/A, urine C&S
• CBC and differential: leukocytosis, left shift
• imaging indicated if suspicious of complicated pyelonephritis or symptoms do not improve with 48-72 h of treatment
  - abdominal/pelvic U/S
  - CT
• nuclear medicine: DMSA scan can be used to help secure the diagnosis
  - a photopenic defect indicates active infection or scar; if normal alternative diagnoses should be considered

Treatment
• hemodynamically stable
  - outpatient oral ABx treatment ± single initial IV dose (see Table 8)
• severe or non-resolving
  - admit, hydrate, and treat with IV ABx (see Table 8)
• emphysematous pyelonephritis
  - percutaneous nephrostomy tube and antibiotics first line
  - consider early nephrectomy after IV ABx started and patient stabilized
• renal obstruction
  - admit for emergent stenting or percutaneous nephrostomy tube

Prostatitis/Prostatodynia
Epidemiology
• most common urologic diagnosis in men <50 yr
• prevalence 2-12%

Nitrofurantoin has poor tissue penetration and therefore is not used to treat pyelonephritis (requires post-renal uroconcentration)

It is not recommended to do a serum PSA during acute bacterial prostatitis

---

## Epididymitis and Orchitis

### Etiology

- **common infectious causes**
  - <35 yr: *N. gonorrhoeae* or *Chlamydia trachomatis*
  - ≥35 yr or penetrative anal intercourse: GI organisms (especially *E. coli*)
- **other causes**
  - mumps infection may involve orchitis, post-parotitis
  - TB
  - syphilis
  - granulomatous (autoimmune) in elderly men
  - amiodarone (involves only head of epididymis)
  - chemical: reflux of urine into ejaculatory ducts

### Risk Factors

- UTI
- unprotected sexual contact
- instrumentation/catheterization
- increased pressure in prostatic urethra (straining, voiding, heavy lifting) may cause reflux of urine along vas deferens → sterile epididymitis
- immunocompromise

### Clinical Features

- sudden onset scrotal pain and swelling ± radiation along cord to flank
- scrotal erythema and tenderness
- fever
- storage symptoms, purulent d/c
- reactive hydrocele

### Investigations

- U/A, urine C&S
- urothral d/c: Gram stain/culture
- if diagnosis uncertain, must do
  - color-flow Doppler U/S to r/o testicular torsion

### Treatment

- r/o torsion (see Investigations and Table 23, U28)
- see Table 8 for ABx therapy
- scrotal support, bed rest, ice, analgesia

### Complications

- if severe → testicular atrophy
- 30% have persistent infertility problems

---

**Prehn’s Sign:** pain may be relieved with elevation of testicles in epididymitis but not in testicular torsion. Poor sensitivity, especially in children

**If unsure between diagnoses of epididymitis and torsion, always go to OR**

Remember: torsion >6 h has poor prognosis

**Inadequately treated acute epididymitis may lead to chronic epididymitis or epididymo-orchitis**
# Urethritis

**Etiology**
- infectious or inflammatory (e.g. reactive arthritis)

</tbody>
</table>

**Location of Stones**
- calyx: may cause flank discomfort, persistent infection, persistent hematuria, or remain asymptomatic
- pelvis: tend to cause obstruction at UPJ, may cause persistent infection
- ureter: <5 mm diameter will pass spontaneously in 75% of patients

**Stone Pathogenesis**
- supersaturation of stone constituents (at appropriate temperature and pH)
- stasis, low flow, and low volume of urine (dehydration)
- crystal formation and stone nidus
- loss of inhibitory factors
  - citrate (forms soluble complex with calcium)
  - magnesium (forms soluble complex with oxalate)
  - pyrophosphate
  - Tamm-Horsfall glycoprotein

---

# Stone Disease

**Epidemiology**
- prevalence of 2-3%
- M:F = 3:1
- peak incidence 30-50 yr of age
- recurrence rate: 10% at one yr, 50% at 5 yr, 60-80% lifetime

**Risk Factors**
- hereditary: RTA, Glucose-6-phosphate dehydrogenase deficiency, cystinuria, xanthinuria, oxaluria, etc.
- lifestyle: minimal fluid intake; excess vitamin C, oxalate, purines, calcium
- medications: loop diuretics (furosemide, bumetanide), acetazolamide, topiramate, and zonisamide
- medical conditions: UTI (with urea-splitting organisms: Proteus, Pseudomonas, Providencia, Klebsiella, Mycoplasma, Serratia, S. aureus), myeloproliferative disorders, IBD, gout, DM, hypercalcemia disorders (hyperparathyroidism, tumor lysis syndrome, sarcoidosis, histoplasmosis), obesity (BMI >30)

**Clinical Features**
- urinary obstruction → upstream distention → pain
  - flank pain from renal capsular distension (non-colicky)
  - severe waxing and waning pain radiating from flank to groin, testis, or tip of penis due to stretching of collecting system or ureter (ureteral colic)
- writhing, never comfortable, nausea, vomiting, hematuria (90% microscopic), diaphoresis, tachycardia, tachypnea
- occasionally symptoms of trigonal irritation (frequency, urgency)
- bladder stones result in: storage and voiding LUTS, terminal hematuria, suprapubic pain
- if fever, r/o concurrent pyelonephritis and/or obstruction

---

If culture negative or unresponsive to treatment consider: *Ureaplasma urealyticum*, *Mycoplasma genitalium*, *Trichomonas vaginalis*, HSV, or adenovirus

Reactive Arthritis (formerly known as Reiter’s syndrome)
- Urethritis, uveitis (or conjunctivitis), and arthritis
  - (can’t pee, can’t see, can’t climb a tree)

Key Points in Stone Hx
- Diet (especially FLUID INTAKE)
- Predisposing medical conditions
- Predisposing medications
- Previous episodes/investigations/treatments
- Family Hx (1st degree relative)

The four narrowest passage points for upper tract stones are:
- UPJ
- Pelvic brim
- Under vas deferens/broad ligament
- UVJ

<td>Not good at visualizing stones in ureter</td>
<td>–</td>
</tr>
</tbody>
</table>

**Treatment – Acute**

- **medical**
  - analgesic ± antiemetic
  - NSAIDs help lower intra-ureteral pressure
  - medical expulsion therapy (MET)
    - α-blockers: increase rate of spontaneous passage in distal ureteral stones
    - calcium channel blockers
  - ± Abx for bacteriuria
  - IV fluids if vomiting (note: IV fluids do NOT promote stone passage)
- **interventional**
  - required if obstruction endangers patient, e.g. sepsis, renal failure
  - first line: ureteric stent (via cystoscopy)
  - second line: image-guided percutaneous nephrostomy
  - admit if necessary
    - see sidebar: *Indications for Admission to Hospital*

**Treatment – Elective**

- **medical**
  - likely conservative if ureteral stone <10 mm or kidney stone <5 mm and no complications/symptoms well controlled
  - stones <3 mm especially likely to pass spontaneously
  - PO fluids to increase urine volume to >2 L/d (3-4 L if cystine) and MET
  - specific to stone type (see Table 13)
  - periodic imaging to monitor stone position and assess for hydronephrosis
  - progress to interventional stone removal methods if symptoms worsen or fail to improve (indicating stone passage)

**Indications for Admission to Hospital**

- Intractable pain
- Intractable vomiting
- Fever (suggests infection)
- Compromised renal function (including single kidney, bilateral obstructing stone)
- Pregnancy

**Stones and Infection**

If septic, urgent decompression via ureteric stent or percutaneous nephrostomy is indicated. Definitive treatment of the stone should be delayed until the sepsis has cleared.

**Dissolution therapy**

- Uric acid stone
- Non-uric acid stone
- Intervention
- Observation

**Intervention**

- Helical CT Abdomen/Pelvis
- CT shows stone
- KUB x-ray
- CT shows no stone – Consider alternate causes

**Urgent Intervention required if:**

1. Solitary kidney
2. Bilateral stones
3. Intractable pain or vomiting
4. Acute renal failure

**Non-urgent pathway**

- Likelihood of stone passage
- Low
- High

**24 h urine collections must be done**

AFTER discontinuing stone preventing/promoting medications

**Detailed metabolic studies are NOT recommended unless complex patient (recent stone formers, pregnancy, pediatrics, strong family hx, underlying kidney or systemic disease, etc.)**

**α-blockers as Medical Expulsive Therapy for Ureteral Stones**

*Cochrane DB Syst Rev 2014;4:CD008509*

**Purpose:** To determine whether or not α-blockers compared with other pharmacological treatments or placebo improve stone clearance rates and other clinically relevant outcomes in patients presenting with symptoms of stones less than 10 mm confirmed by imaging.

**Results/Conclusions:** 32 RCTs, 5,864 participants.

- Although patients using α-blockers were more likely to experience adverse effects compared to standard therapy, stone-free rates were significantly higher in the α-blocker group (RR 1.48, 95% CI 1.33-1.64), with a reduction in the number of pain episodes (MD -0.48, 95% CI -0.94 to -0.01), the need for analgesic medication (MD -38.17, 95% CI -74.93 to -1.41), and hospitalization (RR 0.35, 95% CI 0.13-0.97).

- α-blockers should therefore be offered as a primary treatment modality for ureteral stones.
• interventional
  • kidney
    • may stent prior to ESWL if stone is 1.5-2.5 cm
    • ESWL if stone <2 cm
    • PCNL if stone >2 cm
  • ureteral stones >10 mm
    • ESWL and URS are both first line treatment modalities for all locations
      – URS has significantly greater stone-free rates for stones at all locations in ureter, but
        also has higher complication rates (ureter perforation, stricture formation, etc.)
    • PCNL is second line treatment
    • laparoscopic or open stone removal (very rare)
  • bladder
    • transurethral stone removal or cystolitholapaxy
    • remove outflow obstruction (TURP or stricture dilatation)

Prevention
• dietary modification
  • increase fluid (>2 L/d), K+ intake
  • reduce animal protein, oxalate, Na+, sucrose, and fructose intake
  • avoid high-dose vitamin C supplements
• medications:
  • thiazide diuretics for hypercalciuria
  • allopurinol for hyperuricosuria
  • potassium citrate for hypocitraturia, hyperuricosuria

Consideration must be given to monitoring stone formers with periodic imaging (i.e. at 1 yr and then q2-4yr based on likelihood of recurrence)

Key Features
| Treatment | Medical if stone <5 mm and no complications |
|-----------|
| Procedural/Surgical treatment if stone >5 mm or presence of complications (see U17 for treatment) |

| Fluids to increase urine volume to >2 L/d |
| For calcium stones: cellulose phosphate, orthophosphate for absorptive causes |
| Calcium oxalate: thiazides, ± potassium citrate, ± allopurinol |
| Calcium struvite: ABx (stone must be removed to treat infection) |

| Increased fluid intake |
| Alkalization of urine to pH 6.5 to 7 (bicarbonate, potassium citrate) ± allopurinol |

| Complete stone clearance |
| ABx for 6 wk |
| Regular follow-up urine cultures |

| Increased fluid intake (3-4 L of urine/d) |
| Alkalize urine (bicarbonate, potassium citrate), Penicillamine ±MPG or Captopril (form complex with cystine) |
| ESWL not effective |
Urological Neoplasms

Approach to Renal Mass

Figure 9. Workup of a renal mass
*Imaging modality may be different in cases of contrast allergy or elevated creatinine

Benign Renal Neoplasms

CYSTIC KIDNEY DISEASE
- **simple cysts**: usually solitary or unilateral
  - usually incidental finding on abdominal imaging
  - **Bosniak Classification** is used to stratify for risk of malignancy based on cyst features from contrast CT
- **polycystic kidney disease**
  - autosomal recessive: multiple bilateral cysts, often leading to early renal failure in infants
  - autosomal dominant: progressive bilateral disease leading to HTN and renal failure, adult-onset
- **medullary sponge kidney**: cystic dilatation of the collecting ducts
  - usually benign course, but patients are predisposed to stone disease
- **von Hippel-Lindau syndrome**: multiple bilateral cysts or clear cell carcinomas (50% incidence of RCC)
  - renal cysts, cerebellar, spinal and retinal hemangioblastomas, pancreatic and epididymal cysts, pheochromocytomas

</table>

**Malignant Renal Neoplasms**

**RENAL CELL CARCINOMA**

**Etiology**
- cause unknown
- originates from proximal convoluted tubule epithelial cells in clear cell subtype (most common)
- hereditary forms seen with von Hippel-Lindau syndrome and hereditary papillary renal carcinoma

**Epidemiology**
- 8th most common malignancy (accounts for 3% of all newly diagnosed cancers)
- 85% of primary malignant tumors in kidney
- M:F = 3:2
- peak incidence at 50-60 yr of age

**Pathology**
- histological subtypes: clear cell (75-85%), papillary (10-15%), chromophobic (5-10%), collecting duct
- sarcomatoid elements in any subtype is a poor prognostic factor

**Risk Factors**
- top 3 risk factors: smoking, HTN, obesity
- miscellaneous: horseshoe kidney, acquired renal cystic disease
- role of environmental exposures (aromatic hydrocarbons, etc.) remains an unproven risk factor for development of RCC

**Clinical Features**
- usually asymptomatic; frequently diagnosed incidentally by U/S or CT
- poor prognostic indicators: weight loss, weakness, anemia, bone pain
- classic “too late triad” found in 10-15%
  - gross hematuria 50%
  - flank pain <50%
  - palpable mass <30%
- was called the “internist’s tumor” because of paraneoplastic symptomatology – now called the “radiologist’s tumor” because of incidental diagnosis via imaging
- metastases: seen in 1/3rd of new cases; additional 20-40% will go on to develop metastases
  - bone, brain, lung and liver most common site
  - may invade renal veins and inferior vena cava lumen. This may result in ascites, hepatic dysfunction, right atrial tumor, and pulmonary emboli

**Investigations**
- routine labs for paraneoplastic syndromes (CBC, ESR, LFTs, extended electrolytes)
- U/A (60-75% have hematuria)
- renal U/S: solid vs. cystic lesion

**RCC Systemic Effects:**
- paraneoplastic syndromes (10-40% of patients)
  - Hematopoietic disturbances: anemia, polycythemia, raised ESR
  - Endocrinopathies: hypercalcemia (increased vitamin D hydroxylation), erythrocytosis (increased erythropoietin), HTN (increased renin), production of other hormones (prolactin, gonadotropins, TSH, insulin, and cortisol)
  - Hepatic cell dysfunction or Stauffer syndrome: abnormal LFTs, decreased WBC count, fever, areas of hepatic necrosis; no evidence of metastases; reversible following removal of primary tumor
  - Hemodynamic alterations: systolic HTN (due to AV shunting), peripheral edema (due to caval obstruction)
• contrast-enhanced CT: higher sensitivity than U/S for detection of renal masses and for staging purposes
• MRI: useful for evaluation of vascular extension
• renal biopsy: to confirm diagnosis if considering observation or other non-surgical therapy

Staging
• involves CT, CXR, liver enzymes and LFTs, bone/head imaging (if symptoms dictate)

| Table 16. 2010 TNM Classification of Renal Cell Carcinoma |
|---|---|---|
| T | N | M |
| T1: tumor <7 cm, confined to renal parenchyma | N0: no regional nodes | M0: no evidence of metastasis |
| T1a: <4 cm | N1: metastasis to a single node, < 2 cm | M1: presence of distant metastasis |
| T1b: 4-7 cm | N2: metastasis to a single node between 2 and 5 cm or multiple nodes < 2 cm |
| T2: tumor >7 cm, confined to renal parenchyma | N3: node >5 cm |
| T2a: tumor >7 cm but ≤10 cm in greatest dimension, limited to the kidney | |
| T2b: tumor >10 cm, limited to the kidney | |
| T3: tumor extends into major veins or perinephric tissues, but NOT into ipsilateral adrenal or beyond Gerota’s fascia | |
| T3a: into renal vein or sinus fat | |
| T3b: into infradiaphragmatic IVC | |
| T3c: into supradiaphragmatic IVC | |
| T4: tumor extends beyond Gerota’s fascia including extension into ipsilateral adrenal | |

Treatment
• surgical
  ▪ radical nephrectomy: en bloc removal of kidney, tumor, ipsilateral adrenal gland (in upper pole tumors) and intact Gerota's capsule and paraaortic lymphadenectomy
  ▪ partial nephrectomy (parenchyma-sparing): small tumor (roughly <4 cm) or solitary kidney/bilateral tumors
  ▪ surgical removal of solitary metastasis may be considered
• ablative techniques (cryoablation, REA)
• palliative radiation to painful bony lesions
• therapy for advanced stage
  ▪ tyrosine kinase inhibitors for metastatic disease (e.g. sunitinib, sorafenib)
  ▪ anti-angiogenesis/anti-VEGF (e.g. bevacizumab)
  ▪ mTOR inhibitors (e.g. temsirolimus, everolimus)
  ▪ high-dose IL-2 (high toxicity but able to induce long-term cure in 5-7% of patients)
  ▪ IFN α: monotherapy has been largely replaced by molecularly targeted agents listed above

Prognosis
• stage at diagnosis most important prognostic factor
  ▪ T1: 90-100% 5 yr survival
  ▪ T2-T3: 60% 5 yr survival
  ▪ metastatic disease: <5% 10 yr survival

Carcinoma of the Renal Pelvis and Ureter

Etiology
• risk factors include
  ▪ smoking
  ▪ chemicals/dietary exposures (industrial dyes and solvents; aristolochic acid)
  ▪ analgesic abuse (acetaminophen, ASA, and phenacetin)
  ▪ Balkan nephropathy

Epidemiology
• rare: accounts for 5% of all urothelial cancers
• frequently multifocal, 2-5% are bilateral
• M:F = 3:1
• relative incidence: bladder:renal:ureter = 100:10:1

Pathology
• 85% are papillary UCC; others include SCC and adenocarcinoma
• UCC of ureter and renal pelvis are histologically similar to bladder UCC

Clinical Features
• gross/microscopic hematuria
• flank pain
• storage or voiding symptoms (dysuria only if lower urinary tract involved)
• flank mass ± hydronephrosis (10-20%)

Axitinib vs. Sorafenib as Second-Line Treatment for Advanced Renal Cell Carcinoma: Overall Survival Analysis and Updated Results from a Randomized Phase 3 Trial

| Study: Phase 3 trial of patients with clear cell metastatic renal cell carcinoma randomized to receive axitinib 5 mg twice daily (n=361) or sorafenib 400 mg twice daily (n=362). |
|---|---|
| Results: Median overall survival was 20.1 mo with axitinib (16.7-23.4) and 19.2 mo with sorafenib (17.5-22.3) (HR 0.989, 95% CI 0.890-1.094). Median progression-free survival was 8.3 mo with axitinib (6.7-9.5) and 6.7 mo with sorafenib (4.4-6.9) (HR 0.656, 95% CI 0.502-0.878). |
| Conclusions: Axitinib should be a second-line treatment option for patients with metastatic renal cell carcinoma. |
Investigations
- IVP/CT urogram
- cystoscopy and retrograde pyelogram

Treatment
- radical nephroureterectomy with cuff of bladder
- distal ureterectomy for distal ureteral tumors
- emerging role for endoscopic laser ablation in patients with low grade disease, poor baseline renal health

Bladder Carcinoma

Etiology
- unknown, but environmental risk factors include
  - smoking (main factor – implicated in 60% of new cases)
  - aromatic amines: naphthylamines, benzidine, tryptophan, phenacetin metabolites
  - cyclophosphamide
  - prior Hx of radiation treatment to the pelvis
  - Schistosoma hematothium infection (associated with SCC)
  - chronic irritation: cystitis, chronic catheterization, bladder stones (associated with SCC)
  - aristolochic acid: associated with Balkan Nephropathy (renal failure, upper tract urothelial cancer) and Chinese Herbal Nephropathy

Epidemiology
- 2nd most common urological malignancy
- M:F = 3:1, more common among whites than blacks
- mean age at diagnosis is 65 yr

Pathology
- classification
  - UCC >90%
  - SCC 5-7%
  - adenocarcinoma 1%
  - others <1%
- stages and prognoses of urothelial carcinoma at diagnosis
  - non-muscle invasive (75%) → >80% overall survival
  - the majority of these patients will have recurrence
  - invasive (25%) → 50-60% 5 yr survival
  - 85% have no prior hx of superficial UCC (i.e. de novo)
  - 50% have occult metastases at diagnosis, and most of these will develop overt clinical evidence of metastases within 1 yr – lymph nodes, lung, peritoneum, liver
- carcinoma in situ → flat, non-papillary erythematous lesion characterized by dysplasia confined to urothelium
  - more aggressive, worse prognosis
  - usually multifocal
  - may progress to invasive UCC

Clinical Features
- asymptomatic (20%)
- hematuria (key symptom: 85-90% at the time of diagnosis)
- pain (50%) → location determined by size/extent of tumor (i.e. flank, suprapubic, perineal, abdominal, etc.)
- clot retention (17%)
- storage urinary symptoms → consider carcinoma in situ
- palpable mass on bimanual exam → likely muscle invasion
- obstruction of ureters → hydronephrosis and uremia (nausea, vomiting, and diarrhea)

Investigations
- U/A, urine C&S, urine cytology
- U/S
- CT scan with contrast → look for filling defect
- cystoscopy with biopsy (gold standard)
- biopsy to establish diagnosis and to determine depth of penetration
- specific bladder tumor markers (e.g. NMP-22, BTA, Immunocyt, FDP)

Grading
- low grade: ≤10% invasive, 60% recur
- high grade: 50-80% are invasive or should progress to invasive over time

Staging
- for invasive disease: CT or MRI, CXR, LFTs, extended electrolytes (Ca^{2+}, Mg^{2+}, PO_{4}^{-3}) (metastatic workup)

Differential Diagnosis of Filling Defect
- Urothelial carcinoma (differentiate via cytology and CT scan)
- Uric acid stone (differentiate via cytology and CT scan)
- Blood clot
- Pyelitis cystica
- Papillary necrosis
- Fungus ball
- Gas bubble from gas producing organisms

Radiotherapy with or without Chemotherapy in Muscle-Invasive Bladder Cancer
- NEJM. 2012;366:1477-1488
- Study: Phase 3 trial with random assignment of 360 patients with muscle-invasive bladder cancer to radiotherapy with or without chemotherapy.
- Results: At 2 yr, rates of locoregional disease-free survival were 67% in the chemoradiotherapy group and 54% in the radiotherapy group (HR 0.68, 95% CI 0.48-0.96). Five year overall survival rates were 48% in the chemoradiotherapy group and 35% in the radiotherapy group (HR 0.82, 95% CI 0.63-1.09).
- Conclusions: Chemotherapy with fluorouracil and mitomycin C in combination with radiotherapy improves locoregional control of bladder cancer compared to radiotherapy alone, with no significant increase in adverse events.

The ENTIRE urinary tract must be evaluated in patients with hematuria unless there is clear evidence of glomerular bleeding (e.g. red cell casts, dysmorphic RBCs, etc.)

Unexplained hematuria in any individual >40 yr old must be investigated to r/o a malignancy

Cystoscopy is the initial procedure of choice for the diagnosis and staging of urothelial malignancy

Tumor grade is the single most important prognostic factor for progression

Figure 11. Urothelial carcinoma of bladder

Treatment
- superficial (non-muscle invasive) disease: Tis, Ta, T1
  - low-grade disease
    - single dose mitomycin c within 24 h of resection reduces recurrence rates
  - high-grade
    - TURBT + intravesical chemo/immuno-therapy (e.g. BCG, mitomycin C) to decrease recurrence rate
    - maintenance with intravesical chemotherapy with BCG for 3 cycles every 3 mo, may be continued for 2-3 yr
- invasive disease: T2a, T2b, T3
  - radical cystectomy + pelvic lymphadenectomy with urinary diversion (e.g. ileal conduit, Indiana pouch, ileal neobladder) or TURBT + chemo-radiation (bladder sparing) for small tumors with non-obstructed ureters
  - neo-adjuvant chemotherapy prior to cystectomy may also be done
  - use of adjuvant chemotherapy after definitive local treatment is controversial
- advanced/metastatic disease: T4a, T4b, N+, M+
  - initial combination of systemic chemotherapy ± irradiation ± surgery

Prognosis
- depends on stage, grade, size, number of lesions, recurrence and presence of CIS
  - T1: 90% 5 yr survival
  - T2: 55% 5 yr survival
  - T3: 20% 5 yr survival
  - T4/N+/M+: <5% 5 yr survival

Prostate Cancer

Etiology
- not known
- risk factors
  - increased incidence in persons of African descent
  - high dietary fat = 2x risk
family Hx
- 1st degree relative = 2x risk
- 1st and 2nd degree relatives = 9x risk

Epidemiology
- most prevalent cancer in males
- 3rd leading cause of male cancer deaths (following lung and colon)
- up to 50% risk of CaP at age 50
- lifetime risk of death from CaP is 3%
- 75% diagnosed between 60-85 yr; mean age at diagnosis is 72

Pathology
- adenocarcinoma
  - >95%, often multifocal
- urothelial carcinoma of the prostate (4.5%)
  - associated with UCC of bladder; does NOT follow TNM staging below; not hormone-responsive
- endometrial (rare)
  - carcinoma of the utricle

Anatomy (see Figure 7, U7)
- 60-70% of nodules arise in the peripheral zone
- 10-20% arise in the transition zone
- 5-10% arise in the central zone

Clinical Features
- usually asymptomatic
- most commonly detected by DRE, elevated PSA, or as an incidental finding on TURP
  - DRE: hard irregular nodule or diffuse dense induration involving one or both lobes
  - PSA: see Prostate Cancer Screening, U25
- locally advanced disease
  - storage and voiding symptoms, ED (all uncommon without spread)
- metastatic disease
  - bony mets to axial skeleton common
  - visceral mets are less common (liver, lung, and adrenal gland most common sites)
  - leg pain and edema with nodal mets obstructing lymphatic and venous drainage

Methods of Spread
- local invasion
- lymphatic spread to regional nodes
  - obturator > iliac > presacral/para-aortic
- hematogenous dissemination occurs early

Investigations
- DRE
- PSA elevated in the majority of patients with CaP
- TRUS-guided needle biopsy
- bone scan may be omitted in untreated CaP with PSA <10 ng/mL
- CT scanning to assess metastases
- MRI: being investigated for possible role in detection, staging, MRI-guided biopsying and active surveillance

</tbody>
</table>
Prostate Specific Antigen

- PSA velocity, PSA density, and free:total PSA: all intended to increase sensitivity and specificity
- measured serum PSA is a combination of free (15%) and bound PSA (85%)
- value of <4 ng/mL traditionally considered as cut-off to differentiate normal from pathologic
- glycoprotein produced by epithelial cells of prostate gland

Prostate Cancer Screening

Digital Rectal Exam
- should be included as part of initial screening
- suspicious findings: abnormal feeling, nodularity, focal lesion, discrete change in texture/fullness/symmetry

Prostate Specific Antigen
- glycoprotein produced by epithelial cells of prostate gland
- leaks into circulation in setting of disrupted glandular architecture
- value of <4 ng/mL traditionally considered as cut-off to differentiate normal from pathologic value, but no single justifiable cutpoint
- measured serum PSA is a combination of free (15%) and bound PSA (85%)
- PSA velocity, PSA density, and freecouting PSA: all intended to increase sensitivity and specificity of serum PSA values
  - association of increased CaP rates with decreased freecouting PSA, elevated PSA velocity and density

Screening Recommendations
- conflicting evidence regarding mortality reduction with PSA-based screening and debate regarding overdiagnosis/ overtreatment
• Ontario Ministry of Health and Long-Term Care and United States Preventative Services Task Force both recommend against PSA testing as a population-wide screening tool.
• however, serum PSA screening recommended in any man with >10 yr life-expectancy and any of the following:
  ▪ suspicious finding on DRE
  ▪ moderate-severe LUTS
  ▪ high risk individuals
  ▪ investigating secondary carcinoma of unknown origin to r/o CaP as primary

**American Urological Association Guidelines (2013) re: Prostate Cancer Screening**
• men under age 40 yr should not have PSA screening (Grade C)
• men aged 40-54 yr should not be screened, unless they have high risk factors (e.g. positive family history or African American race), screening decisions should be individualized (Grade C)
• men aged 55-69 yr should proceed with screening only after shared decision-making on the basis of their values and preferences (Grade B)
• routine screening interval of two years or more may be preferred over annual screening in those men who have participated in shared decision-making and decided on screening (Grade C)
• men aged 70+ years or any man with less than a 10-15 yr life expectancy should not have PSA screening

**Testicular Tumors**

**Etiology/Risk Factors**
• cryptorchidism, atrophy, sex hormones, HIV infection, infertility, family hx, past hx of testicular cancer

**Epidemiology**
• rare, but most common solid malignancy in young males 15-34 yr
• any solid testicular mass or acute hydrocoele in young patient – must r/o malignancy
• slightly more common in right testis (corresponds with slightly higher incidence of right-sided cryptorchidism)
• 2-3% bilateral (simultaneously or successively)

**Pathology**
• primary
  ▪ 1% of all malignancies in males
  ▪ cryptorchidism has increased risk (10-40x) of malignancy
  ▪ 95% are germ cell tumors (all are malignant)
    ▪ seminoma (35%) → classic, anaplastic, spermatocytic
    ▪ NSGCT → embryonal cell carcinoma (20%), teratoma (5%), choriocarcinoma (<1%), yolk sac (<1%), mixed cell type (40%)
  ▪ 5% are non-germ cell tumors (usually benign) → Leydig (testosterone, precocious puberty), Sertoli (gynecomastia, decreased libido)
• secondary
  ▪ male >50 yr
  ▪ usually lymphoma or metastases (e.g. lung, prostate, GI)

**Clinical Features**
• painless testicular enlargement (painful if intratesticular hemorrhage or infarction)
• dull, heavy ache in lower abdomen, anal area or scrotum
• associated hydrocele (10%)
• coincidental trauma (10%)
• infertility (rarely presenting complaint)
• gynecomastia due to secretory tumor effects
• supraclavicular and inguinal lymphadenopathy
• abdominal mass (retroperitoneal lymph node mets)

**Methods of Spread**
• local spread follows lymphatics
  ▪ right → medial, paracaval, anterior and lateral nodes
  ▪ left → left lateral and anterior paraaortic nodes
  ▪ “cross-over” metastases from right to left are fairly common, but no reports from left to right
• hematogenous most commonly to lung, liver, bones, and kidney

**Investigations**
• diagnosis is established by pathological evaluation of specimen obtained by radical inguinal orchidectomy
• tumor markers (β-hCG, LDH, AFP)
  ▪ β-hCG and AFP are positive in 85% of non-seminomatous tumors
  ▪ elevated marker levels return to normal post-operatively if no metastasis
  ▪ β-hCG positive in 7% of pure seminomas, AFP never elevated with seminoma
• testicular U/S (hypoechoic area within tunica albignae = high suspicion of testicular cancer)
• evidence of testicular microcystliasis is not a risk factor for testicular cancer
• needle aspiration contraindicated

**Screening for Prostate Cancer**
Cochrane DB Syst Rev 2013;1:CD004720

**Background:** Screening for prostate cancer has an unclear benefit for reducing prostate cancer-specific mortality and morbidity.

**Study:** Systematic review of randomized clinical trials of screening vs. no screening. A total of 31 trials were retrieved for this review.

**Results:** A meta-analysis of 5 RCTs with 341,342 participants was done. Collectively, there was no significant reduction in prostate cancer-specific mortality within 10 yr of follow-up. Screening procedures and biopsies were commonly associated with bleeding, bruising, and short-term anxiety; subsequent over-diagnosis and overtreatment resulted in additional harms, some severe.

**Conclusions:** Men who have a life expectancy less than 10-15 yr should be informed that screening for prostate cancer is unlikely to be beneficial. Significant harms are associated with screening, over-diagnosis, and overtreatment.
Staging
- Clinical: CXR (lung mets), markers for staging (β-hCG, AFP, LDH), CT abdomen/pelvis (retroperitoneal lymphadenopathy)
  - Stage I: disease limited to testis, epididymis, or spermatic cord
  - Stage II: disease limited to the retroperitoneal nodes
  - Stage III: disease metastatic to supradiaphragmatic nodal or visceral sites

Management
- orchiectomy through inguinal ligament for all stages
- consider sperm banking, testicular prosthesis
- adjuvant therapies

Prognosis
- 99% cured with stage I and II disease
- 70-80% complete remission with advanced disease

Penile Tumors

Epidemiology
- rare (<1% of cancer in males in U.S.)
- most common in 6th decade

Benign
- cyst, hemangioma, nevus, papilloma

Pre-Malignant
- balanitis xerotica obliterans, leukoplakia, Buschke-Lowenstein tumor (large condyloma)

Pre-Invasive Cancer
- carcinoma in situ (CIS)
  - Bowen's disease: crusted, red plaques on the shaft
  - erythroplasia of Queyrat: velvety, ulcerated plaques on the glans
  - treatment options: local excision, laser, radiation, topical 5-fluorouracil

Malignant
- risk factors
  - chronic inflammatory disease
  - STD
  - phimosis
  - uncircumcised penis
  - 2% of all urogenital cancers
  - SCC (>95%), basal cell, melanoma, Paget's disease of the penis (extremely rare)
  - definitive diagnosis requires full thickness biopsy of lesion
  - lymphatic spread (superficial/deep inguinal nodes → iliac nodes) >> hematogenous
Treatment
- wide surgical excision with tumor-free margins (dependent on extent and area of penile involvement) ± lymphadenectomy
- consider less aggressive treatment modalities in CIS (cryotherapy, laser therapy, etc.) if available

</tr>
<tr>
<td>Treatment</td>
<td>Conservative Surgical ligation of testicular veins (balloon, sclerosing agents) Repair may improve sperm count/ motility 50-75%</td>
<td>Conservative Needle aspiration as it can lead to infection, reaccumulation and spilling of irritating sperm within scrotum Excise if symptomatic</td>
<td>Conservative Needle drainage Surgical</td>
<td>Emergency surgical exploration and bilateral orchiopexy Orchiectomy if poor prognosis</td>
<td>Surgical repair</td>
</tr>
</tbody>
</table>
TORSION OF TESTICULAR APPENDIX
- twisting of testicular/epididymal vestigial appendix

Signs and Symptoms
- clinically similar to testicular torsion, but vertical lie and cremaster reflex preserved
- “blue dot sign”
  - blue infarcted appendage seen through scrotal skin (can usually be palpated as small, tender lump)

Treatment
- analgesia – most will subside over 5-7 d
- surgical exploration and excision if refractory pain

HEMATOCELE
- trauma with bleed into tunica vaginalis
- U/S helpful to exclude fracture of testis which requires surgical repair

Treatment
- ice packs, analgesics, surgical repair

Erectile Dysfunction

Definition
- consistent (>3 mo duration) or recurrent inability to obtain or maintain an adequate erection for satisfactory sexual performance

Physiology
- erection involves the coordination of psychologic, neurologic, hemodynamic, mechanical, and endocrine components
- nerves: sympathetic (T11-L2), parasympathetic (S2-4), somatic (dorsal penile/pudendal nerves [S2-4])
- erection ("POINT")
  - parasympathetics → release of nitric oxide (NO) → increased cGMP levels within corpora cavernosa leading to:
    1. arteriolar dilatation
    2. sinusoidal smooth muscle relaxation → increased arterial inflow and compression of penile venous drainage (decreased venous outflow)
- emission ("SHOOT")
  - sensory afferents from glans
  - secretions from prostate, seminal vesicles, and ejaculatory ducts enter prostatic urethra (sympathetics)
- ejaculation ("SHOOT")
  - bladder neck closure (sympathetic)
  - spasmotically contracted bulbocavernous and pelvic floor musculature (somatic)
- detumescence
  - sympathetic nerves, norepinephrine, endothelin-1 → arteriolar and sinusoidal constriction → penile flaccidity

</tbody>
</table>

Etiology ("IMPOTENCE")
- Iatrogenic: pelvic surgery, pelvic radiation
- Mechanical: Peyronie’s, post-priapism
- Psychological: depression, stress, anxiety, PTSD, widower syndrome
- Occlusive vascular: arterial HTN, DM, smoking, hyperlipidemia, PVD, venous (impaired veno-occlusion)
- Trauma: penile/pelvic, bicycling
- Extra factors: renal failure, cirrhosis, COPD, sleep apnea, malnutrition
- Neurogenic: CNS (e.g. Parkinson’s, MS, spinal cord injury, Guillain-Barré, spina bifida, stroke), PNS (e.g. DM, peripheral neuropathy)
- Chemical: antihypertensives, sedatives, antidepressants, antipsychotics, anxiolytics, anticholinergics, antihistamines, anti-androgens (including 5-α reductase inhibitors), statins, GnRH agonists, illicit drugs
- Endocrine: DM, hypogonadism, hyperprolactinemia, hypo/hyperthyroid

Diagnosis
- complete Hx (include sexual, medical, and psychosocial aspects)
- self-administered questionnaires (e.g. International Index of Erectile Function, Sexual Health Inventory for Men Questionnaire, ED Intensity Scale, ED Impact Scale)
- focused P/E, including vascular and neurologic examinations, secondary sexual characteristics
- lab investigations, dependent on clinical picture
  - risk factor evaluation: fasting blood glucose or HbA1c, cholesterol profile
  - optional: TSH, CBC, U/A, testosterone (free and total), prolactin, LH
- specialized testing including nocturnal penile tumescence monitoring usually unnecessary
- evaluation of penile vasculature only relevant with past history of trauma (i.e. pelvic fracture)
Treatment
- can often be managed by family doctor, see sidebar for when to refer
- must fully inform patient/partner of options, benefits and complications
- non-invasive
  - lifestyle changes (alcohol, smoking), psychological (sexual counseling and education)
  - change precipitating medications
  - treat underlying causes (diabetes, CVD, HTN, endocrinopathies)
- minimally invasive
  - oral medication (see Common Medications, U42)
    - sildenafil, tadalafil, vardenafil, avanafil: inhibits PDE-5 to increase intracavernosal cyclic GMP levels
      - all four have similar effectiveness, but tadalafil has certain advantages: earlier onset, longer half-life, no cyanopsia, can be taken on empty or full stomach (others better on empty stomach)
  - vacuum devices: draw blood into penis via negative pressure, then put ring at base of penis once erect
  - MUSE: male urethral suppository for erection – vasoactive substance (PGE1) capsule inserted into urethra
- invasive
  - intracavernous vasodilator injection/self-injection
    - triple therapy (papaverine, phentolamine, PGE1) or PGE1 alone
    - complications: priapism (overdose), thickening of tunica albuginea at site of repeated injections (Peyronie's plaque) and hematoma
- surgical
  - penile implant (last resort): malleable or inflatable
  - penile artery reconstruction (in young men with isolated vascular lesion – investigational)

Trauma

Renal Trauma

Classification According to Severity
- minor
  - contusions and superficial lacerations/hematomas: 90% of all blunt traumas, surgical exploration seldom necessary
- major
  - laceration that extends into medulla and collecting system, major renal vascular injury, shattered kidney

Etiology
- 80% blunt (MVC, assaults, falls) vs. 20% penetrating (stab wounds and gunshots)

Clinical Features
- mechanism of injury raises suspicion
- can be hemodynamically unstable secondary to renal vascular injury and/or other sustained injuries: ABCs
- upper abdominal tenderness, flank tenderness, flank contusions, lower rib/vertebral transverse process fracture

Investigations
- U/A
  - hematuria: requires workup but degree does not correlate with the severity of injury
- imaging
  - CT (contrast, triphasic) if patient stable: look for renal laceration, extravasation of contrast, retroperitoneal hematoma, and associated intra-abdominal organ injury

Staging (Does Not Necessarily Correlate Well with Clinical Status)
- I: contusion/hematoma
- II: <1 cm laceration without urinary extravasation
- III: >1 cm laceration without urinary extravasation
- IV: urinary extravasation
- V: shattered kidney or avulsion of pedicle
Treatment
• microscopic hematuria + isolated well-staged minor injuries → no hospitalization
• gross hematuria + contusion/minor lacerations → hospitalize, bedrest, repeat CT if bleeding persists
• surgical intervention/minimally invasive angiography and embolization:
  ▪ absolute indications
    • hemorrhage and hemodynamic instability
  ▪ relative indications
    • non-viable tissue and major laceration
    • urinary extravasation
    • vascular injury
    • expanding or pulsating peri-renal mass
    • laparotomy for associated injury
• follow-up with U/S or CT before d/c, and at 6 wk

Complications
• HTN in 5% of renal trauma

Bladder Trauma

Classification
• contusions: no urinary extravasation, damage to mucosa or muscularis
• intraperitoneal ruptures: often involve the bladder dome
• extraperitoneal ruptures: involve anterior or lateral bladder wall in full bladder

Etiology
• blunt (MVC, falls, and crush injury) vs. penetrating trauma to lower abdomen, pelvis, or perineum
• blunt trauma is associated with pelvic fracture in 97% of cases

Clinical Features
• abdominal tenderness, distention, peritonitis, and inability to void
• can be hemodynamically unstable secondary to pelvic fracture, other sustained injuries: ABCs
• suprapubic pain

Investigations
• U/A: gross hematuria in 90%
• imaging (including CT cystogram and post-drainage films for extravasation)

Treatment
• penetrating trauma → surgical exploration
• contusion → urethral catheter until hematuria completely resolves
• extraperitoneal bladder perforations → typically non-operative with foley insertion, and follow with cystograms
  ▪ surgery if: infected urine, rectal/vaginal perforation, bony spike into bladder, laparotomy for concurrent injury, bladder neck involvement, persistent urine leak and failed conservative management
• intraperitoneal rupture usually requires surgical repair and suprapubic catheterization

Complications
• complications of bladder injury itself are rare
• mortality is around 20%, and is usually due to associated injuries rather than bladder rupture

Urethral Injuries

Etiology
• posterior urethra
  ▪ common site of injury is junction of membranous and prostatic urethra due to blunt trauma, MVCs, pelvic fracture
  ▪ shearing force on fixed membranous and mobile prostatic urethra
• anterior urethra
  ▪ straddle injury can crush bulbar urethra against pubic rami
• other causes
  ▪ iatrogenic (instrumentation, prosthesis insertion), penile fracture, masturbation with urethral manipulation
• always look for associated bladder rupture
Clinical Features
- blood at urethral meatus
- high-riding prostate on DRE
- swelling and butterfly perineal hematoma
- penile and/or scrotal hematoma
- sensation of voiding without U/O
- distended bladder

Investigations
- must perform RUG or cystoscopy prior to catheterization

Treatment
- simple contusions
  - no treatment
- partial urethral disruption
  - very gentle attempt at catheterization by urologist
  - with no resistance to catheterization → Foley x 2-3 wk
  - with resistance to catheterization → suprapubic cystostomy or urethral catheter alignment in OR
- periodic flow rates/urethrograms to evaluate for stricture formation
- complete disruption
  - immediate repair if patient stable, delayed repair if unstable (suprapubic tube in interim)

Complications
- stricture

Infertility

Definition
- failure to conceive after one year of unprotected, properly timed intercourse
- incidence
  - 15% of all couples
  - ~ 35-40% female, 20% male, 25-30% combined problem

Female Factors
- see Gynecology, GY20

Male Factors

Male Reproduction
- hypothalamic-pituitary-testicular axis (HPTA)
  - pulsatile GnRH from hypothalamus acts on anterior pituitary stimulating release of LH and FSH
  - LH acts on Leydig (interstitial) cells → testosterone synthesis and secretion
  - FSH acts on Sertoli cells → structural and metabolic support to developing spermatogenic cells
  - FSH and testosterone support germ cells (responsible for spermatogenesis)
  - sperm route: epididymis → vas deferens → ejaculatory ducts → prostatic urethra

Etiology
- idiopathic (40-50% infertile males)
- testicular
  - varicocele (35-40% infertile males)
  - tumor
  - congenital (Klinefelter’s triad: small, firm testes, gynecomastia, and azoospermia)
  - post-infectious (epididymo-orchitis, STDs, mumps)
  - uncorrected torsion
  - cryptorchidism (<5% of cases)
- obstructive
  - iatrogenic (surgery: see below)
  - infectious (gonorrhea, chlamydia)
  - trauma
  - congenital (absence of vas deferens, CF)
- bilateral ejaculatory duct obstruction, epididymal obstructions
- Kartagener’s syndrome (autosomal recessive disorder causing defect in action of cilia)
- endocrine (see Endocrinology, E47)
- HPTA (2-3%) e.g. Kallmann’s syndrome (congenital hypothalamic hypogonadism), excess prolactin, excess androgens, excess estrogens
- other
  - retrograde ejaculation secondary to surgery
  - medications
  - drugs: marijuana, cocaine, tobacco, alcohol
  - increased testicular temperature (sauna, hot baths, tight pants or underwear)
  - chronic disease: e.g. liver, renal
  - unexplained infertility

**History**
- age of both partners
- medical: past illness, DM, trauma, CF, genetic syndromes, STDs, cryptorchidism
- surgical: vasectomy, herniorrhaphy, orchidopexy, prostate surgery
- fertility: pubertal onset, previous pregnancies, duration of infertility, treatments
- sexual: libido, erection/ejaculation, timing, frequency
- family Hx
- medications: cytotoxic agents, GnRH agonists, anabolic steroids, nitrofurantoin, cimetidine, sulfasalazine, spironolactone, α-blockers
- social hx: alcohol, tobacco, cocaine, marijuana
- occupational exposures: radiation, heavy metals

**Physical Exam**
- general appearance: sexual development, gynecomastia, obesity
- scrotal exam: size, consistency, and nodularity of testicles; palpation of cord for presence of vas deferens; DRE; Valsalva for varicocele

**Investigations**
- semen analysis (SA) at least 2 specimens, collected 1-2 wk apart
  - delivery to lab within 1 h, 2-7 d of abstinence prior to collection
- hormonal evaluation
  - indicated with abnormal SA (rare to be abnormal with normal SA)
  - serum LH and prolactin are measured if testosterone or FSH are abnormal
- genetic evaluation
  - chromosomal studies (Klinefelter's syndrome – XXY)
  - genetic studies (Y-chromosome microdeletion, CF gene mutation)
- immunologic studies (antisperm antibodies in ejaculate and blood)
- testicular biopsy
- scrotal U/S (varicocele, testicular size)
- vasography (assess patency of vas deferens)

**Treatment**
- assessment of partner
- lifestyle
  - regular exercise, healthy diet
  - eliminate alcohol, tobacco and illicit drugs
- medical
  - endocrine therapy (see Endocrinology, E48)
  - treat retrograde ejaculation
  - discontinue anti-sympathomimetic agents, may start α-adrenergic stimulation (phenylpropanolamine, pseudoephedrine, or ephedrine)
  - treat underlying infections
- surgical
  - varicocelectomy (if indicated)
  - vasovasostomy (vasectomy reversal) or epididymovasostomy
  - transurethral resection of blocked ejaculatory ducts
- assisted reproductive technologies (ART)
  - refer to infertility specialist
  - sperm washing + intrauterine insemination (IUI)
  - *in vitro* fertilization (IVF)
  - intracytoplasmic sperm injection (ICSI) after CF screening of patient and partner in patients with congenital bilateral absence of vas deferens

**WHO Guidelines**
- Normal Semen Values
  - Volume: 2-5 mL
  - Concentration: >15 million sperm/mL
  - Morphology: 30% normal forms
  - Motility: >40% adequate forward progression
  - Liquefaction: complete in 20 min
  - pH: 7.2-7.8
  - WBC: <10/HPF or <10⁶ WBC/mL semen

**Common Terminology on SA**
- Teratospermia: Abnormal morphology
- Asthenospermia: Abnormal motility
- Oligospermia: Decreased sperm count
- Azoospermia: Absent sperm in semen
- Mixed types, i.e. oligoasthenospermia

**Mutation of cystic fibrosis transmembrane conductance regulator (CFTR) gene is associated with congenital bilateral absence of vas deferens and epididymal cysts, even if patient manifests no symptoms of CF**
**Pediatric Urology**

**Congenital Abnormalities**

- not uncommon; 1/200 have congenital abnormalities of the GU tract
- six common presentations of congenital urological abnormalities

### 1. ANTE-NATAL HYDRONEPHROSIS

**Epidemiology**
- 1-5% fetal U/S, detectable as early as first trimester
- most common urological consultation in perinatal period and one of most common U/S abnormalities of pregnancy

**Differential Diagnosis**
- UPJ or UVJ obstruction
- multi-cystic dysplastic kidney
- VUR
- PUVs (only in boys)
- duplication anomalies
- ureterocele
- ectopic ureter

**Treatment**
- antenatal *in utero* intervention rarely indicated unless evidence of PUVs with oligohydramnios

### 2. POSTERIOR URETHRAL VALVES

**Epidemiology**
- the most common congenital obstructive urethral lesion in male infants

**Pathophysiology**
- abnormal mucosal folds at the distal prostatic urethra causing varying degrees of obstruction

**Clinical Presentation**
- dependent on age
  - antenatal: bilateral hydronephrosis, distended bladder, oligohydramnios
  - neonatal (recognized at birth): palpable abdominal mass (distended bladder, hydronephrosis), ascites (transudation of retroperitoneal urine), respiratory distress (pulmonary hypoplasia from oligohydramnios), weak urinary stream
  - neonatal (not recognized at birth): within weeks present with urosepsis, dehydration, electrolyte abnormalities, failure to thrive

---

Figure 15. Infertility workup
• toddlers: UTIs or voiding dysfunction
• school-aged boys: voiding dysfunction → urinary incontinence
• associated findings include renal dysplasia and secondary VUR

**Investigations**
- most commonly recognized on prenatal U/S → bilateral hydronephrosis, thickened bladder, dilated posterior urethra ("keyhole sign"), oligohydramnios in a male fetus
- VCUG → dilated and elongated posterior urethra, trabeculated bladder, VUR

**Treatment**
- immediate catheterization to relieve obstruction, followed by cystoscopic resection of PUV when baby is stable
- if resection of PUV is not possible, vesiostomy is indicated

### 3. URETEROPELVIC JUNCTION OBSTRUCTION

**Etiology**
- unclear: adynamic ureteral segment, stenosis, strictures, extrinsic compression, stenosis, strictures, aberrant blood vessels
- can rarely be secondary to tumor, stone, etc. in children

**Epidemiology**
- the most common congenital defect of the ureter
- M:F = 2:1
- up to 40% bilateral, which may be associated with worse prognosis

**Clinical Presentation**
- symptoms depend on severity and age at diagnosis (mostly asymptomatic finding on antenatal U/S)
  - infants: abdominal mass, urinary infection
  - children: pain, vomiting, failure to thrive
- some cases are diagnosed after puberty and into adulthood
  - in adolescents and adults, the symptoms may be triggered by episodes of increased diuresis, such as following alcohol ingestion (Dietl’s crisis)

**Investigations**
- antenatal U/S most common, Doppler U/S (rare), IVP (rare), and renal scan ± furosemide

**Treatment**
- surgical correction (pyeloplasty), consider nephrectomy if <15% differential renal function

### 4. VESICOURETERAL REFLUX

**Definition**
- retrograde passage of urine from the bladder, through the UVJ, into the ureter

**Classification**
- primary reflux: incompetent or inadequate closure of UVJ
  - lateral ureteral insertion, short submucosal segment
- secondary reflux: abnormally high intravesical pressure resulting in failure of UVJ closure
  - often associated with anatomic (PUV) or functional (neuropathic) bladder obstruction

**Epidemiology**
- estimated ~1% of newborns, but not well known
- incidence and clinical relevance higher in children with febrile UTIs and prenatal hydronephrosis
- risk factors: race (white > black), female gender, age (<2 yr), genetic predisposition

**Investigations**
- focused Hx, particularly of voiding dysfunction (frequency, urgency, diurnal enuresis, constipation, encopresis)
- also screen for signs of infection (UTI, pyelonephritis, urosepsis) and renal failure (uremia, HTN)
- initial evaluation of renal status, growth parameters, and blood pressure is warranted in any child with VUR due to high incidence of renal scarring
  - height, weight, blood pressure
  - Cr

![VUR Grading (based on cystogram)](image)
• U/A, C&S
• renal U/S
• DMSA renal scan if at high risk (greater sensitivity in detecting structural defects associated with dysplasia, renal scarring or pyelonephritis; entails radiation exposure)
• family screening is controversial

Treatment
• spontaneous resolution in 60% of primary reflux
  • in lower grades (I-III), goal is to prevent infection or renal damage via medical treatment and monitoring
• medical treatment: daily ABx prophylaxis at half the treatment dose for acute infection (see Table 8, U12 - TMP/SMX, trimethoprim, amoxicillin, or nitrofurantoin)
• surgical treatment: ureteral reimplantation ± ureteroplasty, or subureteral injection with bulking agents (Deflux® or Macroplastique®)
  • indications include failure of medical management, renal scarring (e.g. renal insufficiency, HTN), breakthrough UTIs, persistent high grade (IV or V) reflux

5. HYPOSPADIAS

Definition
• a condition in which the urethral meatus opens on the ventral side of the penis, proximal to the normal location in the glans penis
• depending on severity, may result in difficulty directing urinary stream, having intercourse or depositing sperm in vagina

Epidemiology
• very common; 1/300 live male births
• distal hypospadias more common than proximal
• white >> black
• may be associated with ventral penile curvature, disorders of sexual differentiation, undescended testicles or inguinal hernia

Treatment
• early surgical correction; optimal repair before 2 yr
• neonatal circumcision should be deferred because the foreskin may be utilized in the correction

6. EPISPADIAS-EXTROPHY COMPLEX

Definition
• a spectrum of defects depending on the timing of the rupture of the cloacal membrane
  • bladder extrophy: congenital absence of a portion of lower abdominal and anterior bladder wall, with exposure of the bladder lumen
  • cloacal extrophy
    • exposed bladder and bowel with imperforate anus
    • associated with spina bifida in >50%
  • epispadias (least severe)
    • urethra opens on dorsal aspect of the penis, often associated with penile curvature

Etiology
• represents failure of closure of the cloacal membrane, resulting in the bladder and urethra opening directly through the abdominal wall

Epidemiology
• rare: incidence 1/30,000, M:F = 3:1 predominance
• high morbidity → multiple reconstructive surgeries, incontinence, infertility, reflux

Treatment
• surgical correction at birth
• later corrections for incontinence, VUR, and low bladder capacity may be needed
Nephroblastoma (Wilms’ Tumor)

Etiology
• arises from abnormal proliferation of metanephric blastema

Epidemiology
• 5% of all childhood cancers, 5% bilateral
• most common primary malignant renal tumor of childhood
• average age of incidence is 3 yr

Clinical Features
• abdominal mass: large, firm, unilateral (80%)
• HTN (25%)
• flank tenderness
• microscopic hematuria
• nausea/vomiting

Treatment
• always investigate contralateral kidney and renal vein (for tumor thrombus)
• unilateral disease: radical nephrectomy ± radiation ± chemotherapy
• bilateral disease: nephron-sparing surgery following neoadjuvant chemotherapy

Prognosis
• 5 yr survival 80%

Cryptorchidism/Ectopic Testes

Definition
• abnormal location of testes somewhere along the normal path of descent (external inguinal ring > inguinal canal > abdominal)
• ectopic testis (testis found outside its normal path of descent) is most commonly located within a superficial pouch between the external oblique fascia and Scarpa’s fascia (Denis Browne pouch)
• differential diagnosis
  • retractile testes
  • atrophic testes
  • disorders of sexual differentiation (bilateral impalpable gonads)

Epidemiology
• 2.7% of full term newborns
• 0.7-0.8% at 1 yr old

Treatment
• orchiopexy
• hormonal therapy not proven to be of benefit over standard surgical treatment

Prognosis
• reduction in fertility
  • untreated bilateral cryptorchidism: ~100% infertility
  • paternity rates: 53%, 90%, and 93% in formerly bilateral cryptorchid, formerly unilateral cryptorchid, and normal men, respectively
• increased malignancy risk
  • intraabdominal > inguinal
• surgical correction facilitates testicular monitoring and may reduce malignancy risk
• increased risk of testicular torsion (reduced by surgical correction)

Disorders of Sexual Differentiation

Definition
• formerly known as intersex disorders
• abnormal genitalia for chromosomal sex due to the undermasculinization of males or the virilization of females
• considered a social emergency

Classification
1. 46 XY DSD
  • defect in testicular synthesis of androgens
  • androgen resistance in target tissues
  • palpable gonad

A phenotypic male newborn with bilateral non-palpable testicles should be considered 46XX with salt-wasting CAH and must undergo proper evaluation prior to discharge

Normal Testicular Development and Descent in Utero

2nd mo: Testicle begins to form
4th mo: Begins to take on its normal appearance and migrates from its origin at the kidney to the internal inguinal ring
7th mo: The testis, surrounded in peritoneal covering, begins to descend through the internal ring, inguinal canal and external ring to terminate in the scrotum
2. 46 XX DSD
   - most due to CAH (21-hydroxylase deficiency most common enzymatic defect) → shunt in steroid biosynthetic pathway leading to excess androgens
   - undiagnosed and untreated CAH can be associated with life-threatening electrolyte abnormalities in the newborn (salt-wasting CAH)

3. ovotesticular DSD

4. mixed gonadal dysgenesis (46 XY/45 XO most common karyotype)
   - presence of Y chromosome → partial testis determination to varying degrees

Diagnosis
- thorough family Hx noting any consanguinity
- maternal Hx, especially medication/drug use during pregnancy (maternal hyperandrogenemia)
- P/E: palpable gonad (= chromosomal male), hyperpigmentation, evidence of dehydration, HTN, stretched phallus length, position of urethral meatus
- laboratory tests
  - plasma 17-OH-progesterone (after 36 h of life) → increased in 21-hydroxylase deficiency (CAH)
  - plasma 11-deoxycortisol → increased in 11-β-hydroxylase deficiency
  - basal adrenal steroid levels
  - serum testosterone and DHT pre- and post-hCG stimulation (2,000 IU/d for 4 d)
  - serum electrolytes
  - chromosomal evaluation including sex karyotype
- U/S of adrenals, gonads, uterus, and fallopian tubes
- endoscopy and genitography of urogenital sinus

Treatment
- steroid supplementation as indicated (e.g. CAH)
- sex assignment after extensive family consultation
  - must consider capacity for sexually functioning genitalia in adulthood, fertility potential, and psychological impact
- reconstruction of external genitalia between 6 and 12 mo
- long-term psychological guidance and support for both patient and family

Enuresis
- see Pediatrics, P9

Selected Urological Procedures

Bladder Catheterization
- catheter size measured by the French (Fr) scale – circumference in mm
- each 1 mm increase in diameter = approximately 3 Fr increase (standard size 16-18 Fr)
- should be removed as soon as possible to reduce the risk of UTI

Continuous Catheterization
- indications
  - accurate monitoring of U/O
  - relief of urinary retention due to medication, neurogenic bladder, or intravesical obstruction
  - temporary therapy for urinary incontinence
  - perineal wounds
  - clot prevention (24-28 Fr) for CBI
  - post-operative

Alternatives to Continuous Catheterization
- intermittent catheterization
  - PVR measurement
  - to obtain sterile diagnostic specimens for U/A, urine C&S
  - management of neurogenic bladder or chronic urinary retention
- condom catheter
- suprapubic catheter

Causes of Difficult Catheterizations and Treatment
- patient discomfort → use sufficient lubrication (± xylocaine)
- collapsing catheter → lubrication as above ± firmer or larger catheter (silastic catheter)
• meatal/urethral stricture → dilate with progressively larger catheters/balloon catheter
• BPH → use coudé catheter as angled tip can help navigate around enlarged prostate
• urethral disruption/obstruction → filiform and followers or suprapubic catheterization
• anxious patient → anxiolytic medication

**Complications of Catheterization**
- infection: UTI
- meatal/urethral trauma

**Contraindications**
- urethral trauma: blood at the meatus of the urethra, scrotal hematoma, pelvic fracture, and/or high riding prostate

### Circumcision

**Definition**
- removal of some or all of the foreskin from the penis

**Epidemiology**
- 30% worldwide
- frequency varies depending on geographic location, religious affiliation, socioeconomic classification

**Medical Indications**
- phimosis and recurrent paraphimosis
- recurrent UTIs (particularly in infants and in association with other urinary abnormalities)
- balanitis xerotica obliterans or other chronic inflammatory conditions

**Contraindications**
- unstable or sick infant
- congenital genital abnormalities (hypospadias)
- family Hx of bleeding disorders warrants laboratory investigation prior to circumcision

**Complications**
- bleeding
- infection
- penile entrapment, skin bridges
- fistula
- glans injury
- penile sensation deficits

### Cystoscopy

**Objective**
- endoscopic inspection of the lower urinary tract (urethra, prostate, bladder, and ureteral orifices), samples for cytology
- scopes can be flexible or rigid

**Indications**
- gross hematuria
- LUTS (storage or voiding)
- urethral and bladder neck strictures
- bladder stones
- bladder tumor surveillance
- evaluation of upper tracts with retrograde pyelography (ureteric stents, catheters)

**Complications**
- during procedure
  - bleeding
  - anesthetic-related
  - perforation (rare)
- post-procedure (short-term)
  - infections, e.g. epididymo-orchitis (rare)
  - urinary retention
- post-procedure (long-term)
  - stricture

---

**Circumcision Status and Risk of HIV and Sexually Transmitted Diseases among Men who have Sex with Men: A Meta-Analysis**

**JAMA 2008;300:1674-1684**

**Purpose:** To describe the association between circumcision and HIV infection and other sexually transmitted diseases (STDs) among men who have sex with men (MSM).

**Methods:** Meta-analysis of 15 studies (n=53,567)

**Results:** The associations between circumcision and HIV-positive and STDs were not statistically significant. Male circumcision had a protective association with HIV in studies of MSM conducted before the introduction of highly active antiretroviral therapy.

**Conclusions:** There is insufficient evidence to support that male circumcision protects against HIV infection or other STDs.

---

**Male Circumcision for Prevention of Heterosexual Acquisition of HIV in Men**

**Cochrane DB Syst Rev 2009;2:CD003362**

**Purpose:** To evaluate the effectiveness and safety of male circumcision for preventing acquisition of HIV in heterosexual men.

**Methods:** The analyzed data is from three randomized controlled trials to assess the efficacy of male circumcision for preventing HIV acquisition in men in Africa.

**Results:** Medical male circumcision reduces the acquisition of HIV by heterosexual men (38%-66% over 24 mo).

---

**Male Circumcision**

**Pediatrics 2012;130:e756-e785**

**Study:** Guidelines by the American Academy of Pediatrics (AAP).

**Recommendations:** The American Academy of Pediatrics radically changed their position on male circumcision in 2012. The report from the AAP now states that the preventative health benefits outweigh the risks of the procedure and that the procedure is well-tolerated with adequate pain management and sterility. Stated benefits include the prevention of urinary tract infection, penile cancer, transmission of some sexually transmitted diseases, including HIV. There is believed to be no effect on penile sexual function, sensitivity or sexual satisfaction. Acute complications are rare and more common if the procedure is done by an untrained provider.

**Note:** The Canadian Pediatric Society (CPS) has not yet updated their position on male circumcision since 1996, which stated that the CPS is opposed to routine circumcision. A new statement is expected soon.
Radical Prostatectomy

Objective
- the removal of the entire prostate and prostatic capsule via a lower midline abdominal incision, laparoscopically or robotically
- internal iliac and obturator vessel lymph nodes may also be dissected and sent for pathology (dependent on risk: clinical stage, grade, PSA)
- seminal vesicle vessels are also partially or completely removed

Indications
- treatment for localized prostate cancer

Complications
- immediate (intraoperative)
  - blood loss
  - rectal injury (extremely rare)
  - ureteral injury (extremely rare)
- perioperative
  - lymphocele formation
- late
  - moderate to severe urinary incontinence (3-10%)
  - mild urinary incontinence (≤20%)
  - ED (~50%, depending on whether one, both, or neither of the neurovascular bundles are involved in extracapsular extension of tumor)

Transurethral Resection of the Prostate

Objective
- to partially resect the periurethral portion of the prostate (transition zone) to decrease symptoms of urinary tract obstruction
- accomplished via a transurethral (cystoscopic) approach using an electrocautery loop, irrigation (glycine), and illumination

Indications
- obstructive uropathy (large bladder diverticula, renal insufficiency)
- refractory urinary retention
- recurrent UTIs
- recurrent gross hematuria
- bladder stones
- intolerance/failure of medical therapy

Complications
- acute
  - intra- or extraperitoneal rupture of the bladder
  - rectal perforation
  - incontinence
  - incision of the ureteral orifice (with subsequent reflux or ureteral stricture)
  - hemorrhage
  - epididymitis
  - sepsis
  - transurethral resection syndrome (also called “post-TURP syndrome”)
    - caused by absorption of a large volume of the hypotonic irrigation solution used, usually through perforated venous sinusoids, leading to a hypervolemic hyponatremic state
    - characterized by dilutional hyponatremia, confusion, nausea, vomiting, HTN, bradycardia, visual disturbances, CHF, and pulmonary edema
    - treat with diuresis and (if severe) hypertonic saline administration
- chronic
  - retrograde ejaculation (>75%)
  - ED (5-10% risk increases with increasing use of cauter)
  - incontinence (<1%)
  - urethral stricture
  - bladder neck contracture
Extracorporeal Shock Wave Lithotripsy

Objective
- to treat renal and ureteral calculi (proximal, middle or distal) which cannot pass through the urinary tract naturally
- shockwaves are generated and focused onto stone → fragmentation, allowing stone fragments to pass spontaneously and less painfully

Indications
- potential first-line therapy for renal and ureteral calculi <2.5 cm
- individuals with calculi in solitary kidney
- individuals with HTN, DM or renal insufficiency
- patient preference and wait-times play a large role in stone management

Contraindications
- acute UTI or urosepsis
- bleeding disorder or coagulopathy
- pregnancy
- obstruction distal to stone

Complications
- bacteriuria
- bacteremia
- post-procedure hematuria
- ureteric obstruction (by stone fragments)
- peri-nephric hematoma

A Comparison of Treatment Modalities for Renal Calculi Between 100 and 300 mm²: Are Shockwave Lithotripsy, Ureteroscopy, and Percutaneous Nephrolithotomy Equivalent? J Endourol 2011;25:481-485

Purpose: To describe the outcomes of a series of patients who underwent shockwave lithotripsy (SWL), ureteroscopy (URS) or percutaneous nephrolithotomy (PCNL).

Methods: Patients treated for intermediate-sized upper tract calculus (100-300 mm²) at a single tertiary center were included. Demographic and clinical data were collected from a prospectively maintained database.

Results: Of 137 patients, 38.7%, 29.9%, and 31.4% were treated with SWL, URS, and PCNL, respectively. Stone-free rate (95.3%) and single treatment success rate (95.3%) were highest for PCNL compared to SWL and URS (p <0.001). When allowing for up to two SWL treatments, success rates became equivalent for the three treatment groups (p = 0.69). Auxiliary treatments were more frequent after SWL compared to URS and PCNL. Clavien grade complications did not differ between the three groups.

Conclusion: Up to two SWL treatments have equivalent success rate as compared to URS and PCNL. Hence, multiple SWL treatments may be a reasonable therapeutic option for patients who prefer SWL or who are not good candidates for alternative therapies.

Note: All anti-cholinergics are equally effective and long-acting formulations are better tolerated. Newer muscarinic M3 receptor specific agents (solifenacin, darifenacin) are equally efficacious as older drugs; however, RCTs based on head-to-head comparison to long-acting formulations are lacking.

Peripheral Arterial Disease

Peripheral Vascular Anatomy

• see Figure 1

Acute Arterial Occlusion/Insufficiency

Definition

• acute occlusion/rupture of a peripheral artery, usually without a history of claudication
• urgent management required: treat within 6 h or irreversible ischemia and myonecrosis may result. Exception is in acute-on-chronic occlusion, because the buildup of collaterals allows time to investigate
• tends to be lower extremity > upper extremity; femoropopliteal > aortoiliac
• etiology embolic vs. thrombotic

Etiology and Risk Factors

Pro-Embolic States

• cardiac arrhythmias (AFib)
• endocarditis
• aneurysms

Hypercoagulable States

• congenital
  • group I (reduced anticoagulants): anti-thrombin, protein C, protein S
  • group II: factor V Leiden, prothrombin, factor VIII, hyper-homocysteinemia
• acquired (increased coagulants): immobility, cancer, pregnancy/OCP, anti-phospholipid antibody syndrome, inflammatory disorders (e.g. IBD), myeloproliferative disorders (e.g. ET), nephrotic syndrome (acquired deficit in protein C and S), disseminated intravascular coagulation (DIC), heparin-induced thrombocytopenia with thrombosis (HITT)
• for presentation of embolus vs. thrombus (see Table 2)

Investigations

• history and physical exam: depending on degree of ischemia may have to forego investigations and go straight to OR
• ABI: extension of physical exam, easily performed at bedside
• ECG, troponin: rule out recent MI or arrhythmia
• CBC: rule out leukocytosis, thrombocytosis or recent drop in platelets in patients receiving heparin
• PT/INR: patient anticoagulated/sub-therapeutic INR
• Echo: identify wall motion abnormalities, intracardiac thrombus, valvular disease, aortic dissection (type A)
• CT angiogram: underlying atherosclerosis, aneurysm, aortic dissection
• conventional catheter based angiography: can be obtained in OR; prelude to thrombolitics
Treatment
- immediate heparinization with 5000 IU bolus and continuous infusion to maintain PTT >60 s
- if impaired neurovascular status: emergent revascularization
- if intact neurovascular status: time for workup (including angiogram)
- definitive treatment
  - embolus: embolectomy
  - thrombus: thrombectomy ± bypass graft ± endovascular therapy
  - irreversible ischemia (complete loss of power or sensation, absent venous and arterial dopplers, rigor): primary amputation
- identify and treat underlying cause
- continue heparin post-operative, start warfarin post-operative day 1 x 3 mo depending on underlying etiology

Complications
- compartment syndrome with prolonged ischemia; requires 4-compartment (anterior/lateral/superficial and deep posterior) fasciotomy
- risk of arrhythmia and death with reperfusion injury
- renal failure and multi-organ failure due to toxic metabolites from ischemic muscle

Prognosis
- 12-15% mortality rate
- 5-40% morbidity rate (amputation)

**Chronic Arterial Occlusion/Insufficiency**

Etiology
- predominantly due to atherosclerosis; primarily lower extremities

Risk Factors
- major: smoking, DM
- minor: HTN, hyperlipidemia, family history, obesity, sedentary lifestyle, PMHx or FMHx CAD/CVD

Clinical Features
- claudication
  1. pain with exertion: usually in calves or any exercising muscle group
  2. relieved by short rest: 2-5 min, and no postural changes necessary
  3. reproducible: same distance to elicit pain, same location of pain, same amount of rest to relieve pain
- critical limb ischemia (CLI)
  1. includes rest pain, night pain, tissue loss (ulceration or gangrene)
  2. pain most commonly over the foot, waking person from sleep, and often relieved by hanging foot off bed
  3. ankle pressure <40 mmHg, toe pressure <30 mmHg, ABI <0.40
- pulses may be absent at some locations, bruits may be present
- signs of poor perfusion: hair loss, hypertrophic nails, atrophic muscle, skin ulcerations and infections, slow capillary refill, prolonged pallor with elevation and rubor on dependency, venous turgor (collapse of superficial veins of foot)
- other manifestations of atherosclerosis: CVD, CAD, impotence, splanchnic ischemia

Investigations
- non-invasive
  - routine blood work, fasting metabolic profile
  - ABI: take highest brachial and highest ankle (dorsalis pedis artery or posterior tibial artery) pressures for each side generally
    - ABI <0.90 abnormal, rest pain appears at <0.30 (see Table 3)
CTA and MRA: excellent for large arteries (aorta, iliac, femoral, popliteal), may have difficulty with tibial arteries (especially in the presence of disease). Both require IV injection of nephrotoxic contrast (iodinated contrast for CT, gadolinium for MR).

Invasive

Arteriography: superior resolution to CTA/MRA, better for tibial arteries, can be done intraoperatively.

</tr>
<tr>
<td>0.50-0.80</td>
<td>Claudication range</td>
</tr>
<tr>
<td>&lt;0.40</td>
<td>Possible critical ischemia</td>
</tr>
</tbody>
</table>

### Treatment

**Conservative**
- Risk factor modification (smoking cessation, HbA1c control, treatment of HTN (ACEI), hyperlipidemia (statin), antplatelet therapy (ECASA))
- Exercise program (30 min 3 times per wk): improves collateral circulation, oxygen extraction at the muscle level
- Foot care (especially in DM): keep wounds clean/dry, avoid trauma and pressure on wounds

**Pharmacotherapy**
- Antiplatelet agents (e.g. ECASA, clopidogrel)
- Cilostazol (cAMP-phosphodiesterase inhibitor with antiplatelet and vasodilatory effects): improves walking distance for some patients with claudication

**Surgical/endovascular**
- Indications: severe lifestyle impairment, vocational impairment, critical ischemia
- Surgical options
  - Endovascular (stenting/angioplasty)
  - Endarterectomy: removal of plaque and repair with patch (usually distal aorta or common/profunda femoral)
  - Bypass graft sites: aortofemoral, axillofemoral, femoropopliteal, distal arterial
    - Graft choices: vein graft (reversed or in situ), synthetic (polytetrafluoroethylene graft (e.g. Gore-Tex®) or Dacron®)
  - Chemical sympathectomy: sympathetic plexus destroyed with EtOH injection into nerve plexus, may stimulate vasodilation (rarely effective)
  - Amputation: if not suitable for revascularization, persistent serious infections/gangrene

### Prognosis

**Claudication:**
- Conservative therapy: 60-80% improve, 20-30% stay the same, 5-10% deteriorate, 5% will require intervention within 5 yr, <4% will require amputation
- For patients with CLI (rest pain, night pain, ulceration or gangrene): high risk of limb loss (which carries 25% risk of death at 1 yr)

---

**Figure 2. Treatment options for CLI**

(A) Algorithm for the treatment of CLI
(B) Surgical treatment options for the treatment of aortoiliac disease

Modified from Beard JD. Chronic lower limb ischemia. BMJ 2000;320:854-857
Aortic Disease

Aortic Anatomy

- see Figure 3

Aortic Dissection

Definition
- tear in aortic intima allowing blood to dissect into the media
- Stanford classification: Type A (involve the ascending aorta) vs. Type B (do not)
- DeBakey Classification: Type I (involves the ascending aorta, aortic arch, and descending aorta), Type II (confined to the ascending aorta) and Type III (confined to the descending aorta distal to the left subclavian artery)
- acute <2 wk (initial mortality 1% per hour for type A dissections)
- chronic >2 wk (mortality levels up to 75-80%)

Etiology
- most common: HTN → degenerative/cystic changes → damage to aortic media
- other: connective tissue disease (e.g. Marfan’s, Ehlers-Danlos), cystic medial necrosis, atherosclerosis, congenital conditions (e.g. coarctation of aorta, bicuspid aortic valves, patent ductus arteriosus), infection (e.g. syphilis), trauma, arteritis (e.g. Takayasu’s)

Epidemiology
- incidence of 5.2 in 1,000,000
- M:F = 3.2:1
- small increased incidence in African-Americans (related to higher incidence of HTN)
- lowest incidence in Asians
- peak incidence 50-65 yr old; 20-40 yr old with connective tissue diseases

Clinical Features
- sudden onset tearing chest pain that radiates to back with:
  - HTN (75-85% of patients)
  - asymmetric BPs and pulses between arms (>30 mmHg difference indicates poor prognosis)
  - ischemic syndromes due to occlusion of aortic branches: coronary (MI), carotids (ischemic stroke, Horner’s syndrome), splanchic (mesenteric ischemia), renal (AKI), peripheral (ischemic leg), intercostal vessels (spinal cord ischemia)
  - “unseating” of aortic valve cusps (new diastolic murmur in 20-30%) in Type A dissection
  - rupture into pleura (dyspnea, hemoptysis) or peritoneum (hypotension, shock) or pericardium (cardiac tamponade)
  - syncope

Investigations
- CXR
  - pleural cap (pleural effusion in lung apices)
  - widened mediastinum
  - left pleural effusion with extravasation of blood
- TEE: can visualize aortic valve and thoracic aorta but not abdominal aorta
- ECG: LVH ± ischemic changes, pericarditis, heart block
- CT (gold standard), aortography, MRA: 100% sensitive and specific
- blood work: lactate (rule out ischemic gut), amylase (rule out pancreatitis), troponin (rule out MI)

Treatment
- pharmacologic
  - β-blocker to lower BP and decrease cardiac contractility
  - use nondihydropyridine CCB if there is a clear contraindication to β-blockers
  - target sBP of 110 mmHg and HR <60 bpm
  - ACEI and/or other vasodilators if insufficient BP or HR control
- surgical
  - urgent surgical consult if thoracic aortic dissection diagnosed or highly suspected
  - Type A to cardiac surgery, Type B to vascular surgery
resection of segment with intimal tear
reconstitution of flow through true lumen
replacement of the affected aorta with prosthetic graft
correction of any predisposing factors
post-operative complications: renal failure, intestinal ischemia, stroke, paraplegia, persistent leg ischemia, death
2/3 of patients die of operative or post-operative complications
Type A: requires emergent surgery with cardiopulmonary bypass
may require
- hypothermic circulation for transverse arch dissections
- resuspension of aortic valve
- aortic valve replacement
- coronary re-implantation for aortic root involvement
initial mortality rate without surgery is 3% per h for first 24 h, 30% 1 wk, 80% 2 wk
Type B: managed medically in absence of spinal/mesenteric/limb malperfusion syndrome
<10-20% require urgent operation for complications
treatment can be surgical or endovascular
require follow-up over time to monitor for dilation
role for early endovascular intervention controversial (2013 INSTEAD trial)
with treatment, 60% 5 yr survival, 40% 10 yr survival

Aortic Aneurysm

Definition of Aneurysm
- localized dilatation of an artery having a diameter at least 1.5x that of the expected normal diameter
true aneurysm: involving all vessel wall layers (intima, media, adventitia)
false aneurysm (also known as pseudo-aneurysm): disruption of the aortic wall or the anastomotic site between vessel and graft with containment of blood by a fibrous capsule made of surrounding tissue
aneurysms can rupture, thrombose, embolize, erode, and fistulize

Classification
- thoracic aortic aneurysm (TAA): ascending, transverse arch, descending
- thoracoabdominal
- abdominal aortic aneurysm (AAA): 90-98% are infrarenal
  - suprarenal: involves one or more visceral arteries, but does not involve the chest
  - pararenal: renal arteries arise from aneurysmal aorta, but the SMA origin is not aneurysmal
  - juxtarenal: the renal arteries originate from normal aorta, but are immediately adjacent to aneurysmal aorta (there is no nonaneurysmal aorta distal to the origin of the renal arteries)
  - infrarenal: The aneurysm originates distal to the renal arteries (there is nonaneurysmal aorta distal to the origins of the renal arteries)

Etiology
- degenerative (atherosclerotic)
- traumatic
- mycotic (Salmonella, Staphylococcus, usually suprarenal aneurysms)
- connective tissue disorder (Marfan syndrome, Ehlers-Danlos syndrome)
- vasculitis
- infectious (syphilis, fungal)
- ascending thoracic aneurysms are associated with bicuspid aortic valve
- risk factors: smoking, HTN, age >70, family history

Epidemiology
- incidence 4.7 to 31.9 per 100,000 for AAA and 5.9 per 100,000 for TAA
- high risk groups
  - ≥65 yr
  - M:F = 3.8:1
  - PVD, CAD, CVD
  - family history of AAA

ACC/AHA 2005 Guidelines define an AAA when the minimum AP diameter of abdominal aorta ≥3.0 cm
Clinical Features
- associated diseases: HTN, PVD, CAD, COPD, renal insufficiency
- most commonly in the abdominal aorta (50% abdominal aorta, 40% thoracic aorta, 10% ascending aorta)
- common presentation: due to acute expansion or disruption of wall
  - syncope
  - pain (chest, abdominal, flank, back)
  - hypotension
  - palpable pulsatile mass above the umbilicus, pulsatile abdominal mass in two directions (expansible)
  - airway or esophageal obstruction, hoarseness (left recurrent laryngeal nerve paralysis), hemoptysis, or hematemia (indicates thoracic or thoracoabdominal aortic aneurysm)
- distal pulses may be intact
- 75% asymptomatic (discovered incidentally)
- uncommon presentation
  - ureteric obstruction and hydronephrosis (often with inflammatory aortic aneurysm)
  - gastrointestinal bleed (duodenal mucosal hemorrhage, aortoduodenal fistula)
  - aortocaval fistula
  - distal embolization (blue toe syndrome)

Investigations
- blood work: CBC, electrolytes, urea, creatinine, PTT, INR, type and cross
- abdominal U/S (100% sensitive, up to ±0.6 cm accuracy in size determination)
- CT (accurate visualization, size determination)
- MRI (accurate visualization, limited access)
- aortogram (only for EVAR)
- Doppler/duplex (rule out vascular tree aneurysms elsewhere, e.g. popliteal)

Treatment
- conservative
  - cardiovascular risk factor reduction: smoking cessation; control of HTN, DM, and hyperlipidemia
  - regular exercise
  - watchful waiting, U/S every 6 mo to 3 yr depending on size and location
- surgical
  - when risk of rupture greater than or equal to risk of surgery (>5.5 cm)
  - risk of rupture depends on
    - size
    - family history of rupture
    - rate of enlargement (if >0.4 cm/yr): >1 cm diameter expansion per year defines "rapid expander"
    - symptoms, comorbidities (HTN, COPD, dissection), smoking
    - elective AAA repair mortality 2-5% for open repair (1-2% for EVAR); elective TAA repair mortality <10% (highest with proximal aortic and thoracoabdominal repairs)
    - consider revascularization for patients with symptomatic or 3-vessel CAD before elective repair of aneurysm
- indications
  - general: ruptured, symptomatic, mycotic, associated with acute Type A dissection or complicated Type B dissection or when risk of rupture is greater than risk of surgery (size >5.5 cm or >2x normal lumen size)

Endoleak Types
- Definition: persistent blood flow into the aneurysm sac
- Type I: ineffective seal at ends of graft
- Type II: backflow from collateral vessels
- Type III: ineffective seal of graft joints or rupture of graft fabric
- Type IV: flow through pores of graft fabric
- Type V: endobronchial, with continued expansion of the aneurysm without apparent flow into the sac

Management of Ruptured AAA
- ABCs
- No imaging (hemodynamically unstable)
- Straight to OR (confirm diagnosis by laparotomy)
- Crossmatch 10 units packed RBCs

Risk of AAA Rupture

<td>≥4.5 cm</td>
<td>Referral to vascular surgeon and repeat ultrasound every 6 mo</td>
</tr>
<tr>
<td>If &gt;1 cm growth in one yr</td>
<td>Referral to vascular surgeon for consideration of repair</td>
</tr>
</tbody>
</table>
ascending thoracic aortic aneurysms
- symptomatic, enlarging, diameter >6 cm or >2x normal lumen size, >4.5 cm and
aortic regurgitation (annuloaortic ectasia); ≥4.5-5 cm in Marfan syndrome
- contraindications: life expectancy <1 yr, terminal disease (e.g. cancer), significant
comorbidities (e.g. recent MI, unstable angina), decreased mental acuity, advanced age
- surgical options
  - open surgery (laparotomy or retroperitoneal) with graft replacement
    - possible complications
    - early: renal failure, spinal cord injury (paraparesis or paraplegia), impotence, arterial
    thrombosis, anastomotic rupture or bleeding, peripheral emboli
    - late: graft infection/thrombosis, aortoenteric fistula, anastomotic (pseudo) aneurysm
  - endovascular aneurysm repair (EVAR)
    - newer procedure; high success rates in patients with suitable anatomy and
    experienced centers
    - advantages: preferred to open surgery in ruptured AAA for patients with suitable
    anatomy, decreased morbidity and mortality, procedure time, need for transfusion,
    ICU admissions, length of hospitalization, and recovery time
    - disadvantages: endoleak rates as high as 20-30%, device failure increasing as longer
    follow-up periods are achieved, re-intervention rates 10-30%, cost-effectiveness is an
    issue (devices are very expensive), radiation exposure
    - complications
      - early: immediate conversion to open repair (<1%), groin hematoma, arterial
      thrombosis, iliac artery rupture, and thromboemboli
      - late: endoleak, severe graft kinking, migration, thrombosis, rupture of aneurysm

Peripheral Venous Disease

Deep Venous Thromboembolism

- see Hematology: H33

Superficial Venous Thrombosis

Definition
- erythema, induration, and tenderness along the superficial vein; usually spontaneous but can
follow venous cannulation

Etiology
- infectious: suppurative phlebitis (complication of IV cannulation; associated with fever/chills)
- trauma
- inflammatory: varicose veins, migratory superficial thrombophlebitis, Buerger’s disease, SLE
- hematologic: polycythemia, thrombocytosis
- neoplastic: occult malignancy (especially pancreatic)
- idiopathic

Clinical Features
- most common in greater saphenous vein and its tributaries
- pain and cord-like swelling along course of involved vein
- areas of induration, erythema, and tenderness correspond to dilated and often thrombosed
superficial veins
- complications
  - simultaneous DVT (up to 20% of cases), PE (rare unless DVT)
  - recurrent superficial thrombophlebitis

Investigations
- non-invasive tests (e.g. Doppler) to exclude associated DVT

Treatment
- conservative
  - moist heat, compression bandages, mild analgesic, anti-inflammatory and anti-platelet
  (e.g. ASA), LMWH, ambulation
- surgical excision of involved vein
  - indication: failure of conservative measures (symptoms that persist over 2 wk)
  - suppurative thrombophlebitis: broad-spectrum IV antibiotics and excision

Type I
Type II
Type III
Type IV
Type V

Migratory superficial thrombophlebitis is often a sign of underlying malignancy
(“Trousseau’s disease”)
Varicose Veins

Definition
- distention of tortuous superficial veins resulting from incompetent valves in the deep, superficial, or perforator systems
- distribution: greater or short saphenous veins and tributaries

Etiology
- primary varicosities: venous valve incompetence or obstruction
  - contributing factors: increasing age, systemic hormonal contraceptive use, occupations requiring long hours of standing, pregnancy, obesity
- secondary varicosities: DVT, malignant pelvic tumors with venous compression, congenital anomalies, arteriovenous fistulae

Epidemiology
- primary varicose veins are the most common form of venous disorder of lower extremity
- 10-20% of population

Clinical Features (Not Correlated with Varicosity Size)
- diffuse aching, fullness/tightness, nocturnal cramping
- aggravated by prolonged standing (end of day), premenstrual
- visible long, dilated and tortuous superficial veins along thigh and leg
- ulceration, hyperpigmentation, and induration (secondary varicosities)
- Brodie-Trendelenburg test (valvular competence test)
  - with patient supine, raise leg and compress saphenous vein at thigh, have patient stand – if veins fill quickly from top down then incompetent valves; use multiple tourniquets to localize incompetent veins

Complications
- recurrent superficial thrombophlebitis
- hemorrhage: external or subcutaneous
- ulceration, eczema, lipodermatosclerosis, and hyperpigmentation

Treatment
- largely a cosmetic problem
- conservative: elevation of leg and/or elastic compression stockings
- surgical: high ligation and stripping of the long saphenous vein and its tributaries, ultrasound-guided foam sclerotherapy, endovenous laser therapy
- indications for surgery: symptomatic varix (pain, bleeding, recurrent thrombophlebitis), tissue changes (hyperpigmentation, ulceration), failure of conservative treatment, cosmetics

Prognosis
- benign course with predictable complications
- almost 100% symptomatic relief with treatment if varicosities are primary
- good cosmetic results with treatment
- significant post-operative recurrence, especially with sclerosing agent injection

Chronic Venous Insufficiency

Definition
- venous insufficiency and skin damage

Etiology
- calf muscle pump dysfunction and valvular incompetence (valvular reflux) due to phlebitis, varicosities, or DVT
- venous obstruction

Clinical Features
- pain (most common), ankle and calf edema – relieved by foot elevation
- pruritus, brownish hyperpigmentation (hemosiderin deposits)
- stasis dermatitis, subcutaneous fibrosis if chronic (lipodermatosclerosis)
- ulceration: shallow, above medial malleolus, weeping (wet), painless, irregular outline
- signs of DVT/varicose veins/thrombophlebitis

Investigations
- Doppler U/S (most commonly used)
- venography (gold standard), or ambulatory venous pressure measurement (not often used)
Treatment
- conservative
  - elastic compression stockings, ambulation, periodic rest-elevation, avoid prolonged standing
  - ulcers: multilayer compression bandage, antibiotics PRN
  - endovenous: laser or radiofrequency ablation, or foam sclerotherapy
- surgical
  - if conservative measures fail, or if recurrent/large ulcers
  - surgical ligation of perforators in region of ulcer (GSV/LSV ligation and stripping)

Carotid Stenosis

Definition
- narrowing of the internal carotid artery lumen due to atherosclerotic plaque formation, usually near common carotid bifurcation into internal and external carotids

Risk Factors
- for atherosclerosis: HTN, smoking, DM, CVD or CAD, dyslipidemia

Clinical Features
- may be asymptomatic
- symptomatic stenosis may present as TIA, RIND, or stroke
- retinal insufficiency or infarct permanently or temporarily (ipsilateral amaurosis fugax), (see Ophthalmology, OP37)
- MCA contralateral occlusive symptoms

Investigations
- CBC, PTT/INR (hypercoagulable states)
- fundoscopy: cholesterol emboli in retinal vessels (Hollenhorst plaques)
- auscultation over carotid bifurcation for bruits (do not correlate with degree of stenosis)
- carotid duplex: determines severity of disease (mild/moderate/severe stenosis of occlusion)
- angiogram: “gold standard” but invasive and 1/200 risk of stroke (not for screening)
- MRA: safer than angiogram, may overestimate stenosis
- CTA

Treatment
- control of HTN, lipids, diabetes
- antiplatelet agents (ASA ± dipyridamole, clopidogrel) ~25% relative risk reduction
- carotid endarterectomy (generally if symptomatic and >70% stenosis)
- endovascular angioplasty ± stenting

Prognosis

Table 4. Symptomatic Carotid Stenosis: North American Symptomatic Carotid Endarterectomy Trial (NASCET)

**Lymphedema**

**Definition**
- obstruction of lymphatic drainage resulting in edema with high protein content

**Etiology**
- primary:
  - Milroy's syndrome: congenital hereditary lymphedema
  - lymphedema praecox (75% of cases): starts in adolescence
  - lymphedema tarda: starts >35 yr
- secondary:
  - infection: filariasis (#1 cause worldwide), post-operative
  - malignant infiltration: axillary, groin or intrapelvic
  - radiation/surgery (axillary, groin lymph node removal): #1 cause in North America

**Clinical Features**
- classically non-pitting edema
- impaired limb mobility, discomfort/pain, psychological distress

**Treatment**
- avoid limb injury (can precipitate or worsen lymphedema)
- skin hygiene
  - daily skin care with moisturizers
  - topical treatment of fungal infection; systemic treatment of bacterial infection
- external support
  - intensive: compression bandages
  - maintenance: lymphedema sleeve
- exercise
  - gentle daily exercise of affected limb, gradually increasing ROM
  - must wear a compression sleeve/bandages when doing exercises
- massage and manual lymph drainage therapy

**Prognosis**
- if left untreated becomes resistant to treatment due to subcutaneous fibrosis
- cellulitis causes rapid increase in swelling; can lead to sepsis and death

Essential Med Notes is a premier study resource for the USMLE Step II and MCCQE medical licensing exams. This edition provides concise and comprehensive information on the objectives covered by these exams, including the most recent best practice guidelines and up-to-date trials for clinical practice. Essential Med Notes is an excellent resource for clinical rotations and this text contains 30 subject-specific chapters:

- Anesthesia and Perioperative Medicine
- Cardiology and Cardiac Surgery
- Clinical Pharmacology
- Dermatology
- Emergency Medicine
- Endocrinology
- Ethical, Legal, and Organizational Medicine
- Family Medicine
- Gastroenterology
- General Surgery
- Geriatric Medicine
- Gynecology
- Hematology
- Infectious Diseases
- Medical Imaging
- Nephrology
- Neurology
- Neurosurgery
- Obstetrics
- Ophthalmology
- Orthopedics
- Otolaryngology
- Pediatrics
- Plastic Surgery
- Population Health and Epidemiology
- Psychiatry
- Respirology
- Rheumatology
- Urology
- Vascular Surgery
