Euclid's Algorithm

**GCDs,
LCMs, and
repeating
decimals**

BY ROBERT T.
KUROSAKA

**DIVISIBILITY
TESTS.**

In my last installment in November, I examined fractions that form repeating decimals. This month, I am going the other way and will look at how to represent repeating decimals as fractions. I concluded the November column with a presentation of the algorithm for converting repeating decimals to fractions. This month's column will include a program to implement that algorithm, which is shown in figure 1.

The most irritating part of the algorithm is step 5, reducing the fraction to lowest terms. Just how do we do that? First, we must find a common divisor, an integer that divides into both the numerator and the denominator. (For this column, "divides into" also implies "without remainder.") Although $24/30$ can be reduced to $12/15$ by dividing the numerator and denominator by 2, we must reduce again to $4/5$ by dividing through by 3. However, I'm sure we all saw that the greatest common divisor (GCD) was 6 and reduced the fraction in one step. As the numerator and denominator get larger, it becomes more difficult to determine what divides into them.

There are a surprisingly large number of folkways for finding divisors of large numbers. Everyone knows that a number is divisible by 2 if its last (rightmost) digit is divisible by 2. A number is divisible by 4 if the last two digits are divisible by 4. For example, 7536 is divisible by 4 since 36 is divisible by 4. This basic pattern can be extended to higher powers of 2: A number is divisible by 8 if its last three digits form a number divisible by 8, and so on.

Similarly, we all know that a number is divisible by 5 if it ends in 0 or 5. A number is divisible by 25 if its last two digits are divisible by 25, by 125 if the final three-digit number is divisible by 125, etc.

As I mentioned in the last column, 2 and 5 are special cases in base 10, so it's not surprising that we can't generalize this to numbers other than powers of 2 and 5. However, there are some methods for other numbers. I'll briefly run down the list of

techniques for other numbers up to 9.

A number is divisible by 3 if the sum of its digits is divisible by 3. For example, 312,798 is divisible by 3 since $3+1+2+7+9+8=30$. Further, it is divisible by 6 because any even number that is divisible by 3 is divisible by 6. A number is divisible by 9 if the sum of its digits is divisible by 9. Thus, 312,798 is not divisible by 9, but 312,795 is ($3+1+2+7+9+5=27$).

The test for divisibility by 7 is rather amusing: "Detach" the last digit and double it, then subtract the result from the rest of the number. If the answer is divisible by 7, the original number is divisible by 7. For example (not that this method needs any clarification), to test 378, we detach the 8 and double it, then subtract 16 from 37. Since the answer, 21, is divisible by 7, so is 378. Try a larger number, 33,929. Detach the 9, double it, and subtract from 3392, giving 3374. Now, is 3374 divisible by 7? You don't know? Apply the test to 3374. (Why is no one laughing?)

Before giving up on these strange tests, let's look at 11. The divisibility test for 11 is a bit complicated but rather impressive. Add every other (alternate) digit in the number; add the remaining digits; if the difference of the two sums is divisible by 11, the number is divisible by 11. In 9,370,845, the first sum is $9+7+8+5=29$, and the second sum is $3+0+4=7$. Since their difference, 22, is divisible by 11, the entire number is divisible by 11. Note also that the sum of all the digits is 36, which is divisible by 9, and that the number ends in 5. Hence, with simple eyeballing, you can be the hit of the party by announcing that 9,370,845 is divisible by 495 ($11 \times 9 \times 5$).

Similar to our last example, you can determine that a number is divisible by 100 by applying our rules for divisibility by 4 and 25. (What? You have an easier way?) Well, perhaps you're beginning to feel that we need a more general method for finding common divisors of fractions. Our first im-

Robert T. Kurosaka teaches mathematics in the Massachusetts State College system. He invites your correspondence to BYTE, POB 372, Hancock, NH 03449.

1. Let x equal the decimal:	$x = 0.7363636...$
2. Multiply the equation by 10^n (# of digits in the cycle)	$100x = 73.6363636...$
3. Subtract 1. from 2.	$99x = 72.9$
4. Solve for x	$x = 72.9/99 = 729/990$
5. Reduce the fraction	$x = 81/110$

Figure 1: The steps in converting repeating decimals to fractions.

(a)	(b)	(c)
$\begin{array}{r} 1581 \overline{) 1734} \\ \underline{1581} \\ 153 \end{array}$	$\begin{array}{r} 153 \overline{) 1581} \\ \underline{1530} \\ 51 \end{array}$	$\begin{array}{r} 51 \overline{) 153} \\ \underline{153} \\ 0 \end{array}$

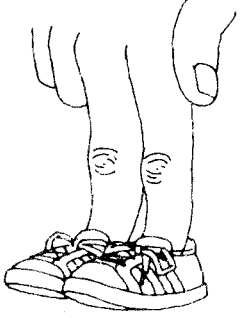

Figure 2: Step-by-step application of Euclid's algorithm to the problem of finding the greatest common divisor of 1734 and 1581.

pulse is to use prime factorization. This is certainly a correct approach, but most prime-factorization subroutines are cumbersome or time-consuming. I will show you a delightfully direct method of finding the GCD of two numbers that is easily programmed and requires no guessing, no trial and error, and no prime factorization. This remarkable method is called Euclid's algorithm.

Let us reduce the fraction 1581/1734. The steps are

1. Divide the larger number by the smaller. In figure 2a, $1734/1581 = 1$ with a remainder of 153.
2. If the remainder is not 0, divide the divisor by the remainder. In figure 2b, $1581/153 = 10$ with a remainder of 51.
3. Repeat step 2 until a 0 remainder occurs. In figure 2c, $153/51 = 3$ with a remainder of 0.

The last divisor is the GCD of the two numbers (most texts call it the last nonzero remainder). In figure 2c, the last divisor is 51. Therefore, the GCD of 1581 and 1734 is 51. And, sure enough, the fraction reduces to 31/34. An obvious but necessary remark: if the GCD is 1, the two numbers are relatively prime; the fraction is already

expressed in lowest terms.

Listing 1 offers a program that reduces a fraction to lowest terms by Euclid's algorithm. [Editor's note: The Microsoft BASIC listings in this column are available for downloading from BYTenet Listings at (617) 861-9764.]

An annoyance related to reducing fractions arises when adding or sub-

tracting fractions with unequal denominators. We need to find the least common denominator (LCD). Before finishing our cyclic decimal-to-reduced-fraction routine, let's take a side trip to shine some light on LCDs.

In $1/9 + 5/12$, we see that the LCD is 36. But precisely what are we seeing?

(continued)

EUCLID

The LCD is the smallest integer that is evenly divisible by both denominators. To put it another way, the LCD is the least common multiple (LCM) of the denominators. While any com-

mon multiple of 9 and 12 will suffice for adding the fractions (e.g., their product, 108), we prefer the least value because it will simplify reducing the fraction later.

With larger denominators, the task of finding the LCD becomes increasingly difficult. In $5/12$ and $3/14$, it is not easily seen that the LCD is 84. Many methods have been devised for finding the LCD, most of which require prime factorization. One rather mystical method works for any number of denominators.

Suppose we want the LCM of 9, 18, and 24. Find a common divisor for all three numbers, if possible. If not, find a common divisor for any two of them, if possible. (If not, the numbers are relatively prime; the LCM is merely the product of the three numbers.)

Figure 3: Finding the least common multiple of three numbers using triple division.

```

We will perform a triple division on these three numbers. In figure 3a, we divide the common divisor 3 into all three numbers. Note that we did not divide the first two numbers by 9 because our precedence of rules requires us to first look for divisors of all the numbers.

Next, we repeat the procedure for the three quotients: 3, 6, and 8. The first two are divisible by 3 again (figure 3b). Important: If the divisor does not divide into a particular number, merely *copy* the number. In figure 3b, the 8 is brought up. This procedure is repeated until all the quotients are 1s. In figure 3c, the 2 and 8 are divided by 2, with the 1 being brought up. Finally, in figure 3d, we divide by 4 and obtain all 1s in the quotients. The LCM is the product of all the divisors used. That is, the LCM of 9, 18, and 24 is $3 \times 3 \times 2 \times 4 = 72$.

You might enjoy trying to write a program to implement this method. There is, however, yet another method for finding the LCM, and, not surprisingly, it employs Euclid's algorithm.

The LCM of two numbers a and b is the product of the numbers divided by their GCD. That is, $LCM(a,b) = a \times b / GCD(a,b)$. This becomes apparent if we look at a simple example: 10 and 14. Their product, 140, is a multiple, but it isn't the smallest one. Since $10 = 2 \times 5$ and $14 = 2 \times 7$, their LCM needs only $2 \times 5 \times 7$, while their product is $2 \times 5 \times 2 \times 7$. Dividing by their GCD of 2 eliminates the overlap. In the language of elementary set theory, the LCM is the union of the two sets of factors. The formula above instructs us to "add" the two sets together and then "subtract" their intersection.

Since we already have the GCD program, we are only one step away from finding the LCM of two numbers. That's the good news. The bad news is that this method works only with two numbers at a time. To find the LCM of three or more numbers (say, 8, 10, and 14), we first find the LCM of 8 and 10 (40) and then find the LCM of 40 and 14 (280). This is no problem for a computer, but you may feel that it is less efficient than our

I use strings, of course, because you can't directly enter a repeating decimal into the computer.

triple-division approach. Anyway, listing 2 presents my version of the LCM routine using Euclid's algorithm.

Finally, we are ready to return to our initial problem of converting a repeating decimal to a fraction. Listing 3 shows my routine for doing steps 1 through 4 of figure 1. The program is mostly a lot of string-handling. I use strings, of course, because you can't directly enter a repeating decimal into the computer. So I use a "—" to signify where the cyclic part begins and enter the number through one iteration of the cycle. This is analogous to the way of writing repeating decimals like $0.333\dots$ as $0.\overline{3}$. Not only are you unable to enter repeating decimals into the computer, the computer is unable to hold any infinite series. However, the point of step 3 is to get rid of the cyclic part. All of the action in the method happens in the nonrepeating part and the first iteration of the cycle. So that is all that we use in our program.

The only really interesting part of this routine is in line 420. After I find the value of the unreduced fraction's numerator and denominator, I convert the values into strings and then back to numbers. Why?

When I first tried writing the routine in listing 3, I used the number $0.7\overline{36}$ as one of my test cases. The routine displayed the numerator value as 72.9 and the denominator value as 99. However, when I merged the routine with listing 1, I got strange results. It seems that Microsoft BASIC's guard digits were nonzero, so when the GCD routine tried to clear the decimal from the 72.9, the fraction became $7.29 \times$
