There is even the possibility of a "fertilizer effect" at low doses, as indicated by the dashed line in Figure 16.6.6. This can be observed, for example, in the dose-response functions for the impact of NO_x

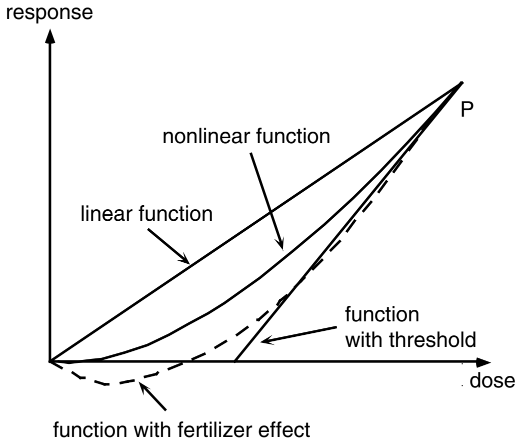

FIGURE 16.6.6 Possible behavior of dose-response functions at low doses: the four functions shown have the same value at P. For the function with threshold, the discontinuity in slope at the threshold is a simplification; in reality there is a smooth transition.

and SO_x on crops: a low dose of these pollutants can increase the crop yield; in other words, the damage is negative. Such a fertilizer effect can occur with pollutants that provide trace elements needed by an organism. It depends on local conditions, in particular the overall balance of nutrients. The fertilizer effect illustrates the link between the understanding of the underlying processes and the choice of the appropriate form for the dose-response function: since N and S are known to be important nutrients for plants, a functional form like the dashed line in Figure 16.6.6 is the most plausible.

If nothing is known about a threshold and a fertilizer effect can be ruled out, the dose-response function could be anywhere between zero and the straight line through the origin, for instance, the curved solid line shown in Figure 16.6.6. *A priori* there is no general rule about the extrapolation to low doses, other than there being apparently no cases of a dose-response function above the straight line. There is even a case where the same substance causes different cancers according to different dose-response functions, one with and one without threshold. This was established in an important experiment where some 24,000 mice were exposed to the carcinogen 2-acetyl-amino-fluorene at several different dose levels (Frith et al. 1981). The response for liver tumor is linear, whereas the one for bladder tumor has a threshold.

Site Dependence of Impacts

Site dependence is illustrated in Figure 16.6.7. This figure shows two variations at once: with stack height, and with source location for five specific sites in France (the nearest big city, 25 to 50 km away, is indicated in parentheses). Plume rise is included for typical conditions of large combustion installations. As an example, we consider a specific impact: the increase in mortality (YOLL = years of life lost) due to an emission of $Q = 10^6$ kg/yr of SO_2 with the dose-response function of Sunyer et al. (1996). The damage is shown on two scales, as number of YOLL per year on the right-hand scale, and in units of D_{uni} (to be explained in a moment) on the left. At a stack height of 100 m the impact for the site near Paris is about 3 times larger than D_{uni} and for Cordemais (a relatively rural site on the Atlantic Ocean) it is about 0.4 times D_{uni}. The impact for Martigues is rather small, despite the proximity of a large city, because the prevailing wind carries the pollutants out to sea.

Site dependence is particularly strong for primary pollutants (i.e., pollutants emitted by a source); this is shown by the examples in Figure 16.6.7. For secondary pollutants (created by chemical reactions of primary pollutants) such as sulfates, nitrates and ozone, the sensitivity to local detail is much lower because these pollutants are not created until some distance from the source. For nitrates and sulfates this occurs over tens to hundreds of km from the source, and so the site dependence is relatively weak;

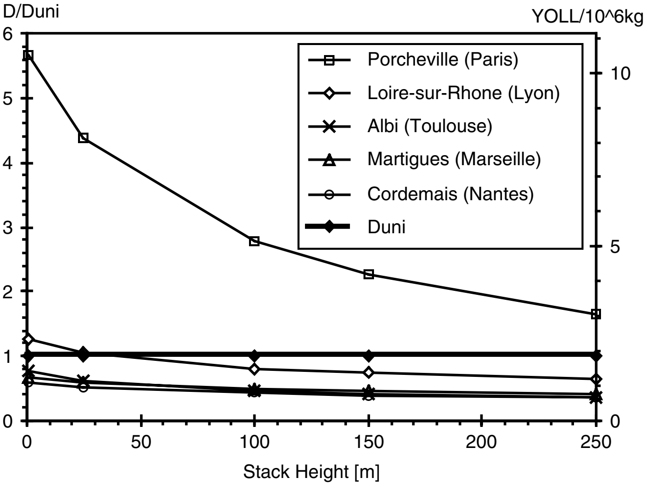

FIGURE 16.6.7 An example of dependence on site and on height of source for a primary pollutant with linear dose-response function: damage D from SO_2 emissions, for five sites in France, in units of D_{uni} for uniform world model Equation 16.6.6 (the nearest big city, 25 to 50 km away, is indicated in parentheses). Scale on right indicates YOLL/yr (acute mortality) from a plant with emission 10^6 kg/yr.

based on EcoSense results, we estimate that variations of sulfate or nitrate damage, per kg of SO_2 or NO_2, with site are around 50%. The creation of ozone is more rapid, within several km to tens of km from the source; based on EMEP data we estimate that ozone damage per kg of precursor could vary with site by about a factor of four in Europe.

To explain D_{uni} (Curtiss and Rabl 1966b) let us write the damage D due to an emission Q as an integral over land area:

$$D = f_{CR} \int dx \int dy \;\; \rho(\mathbf{x}) c(\mathbf{x}) \,. \tag{16.6.32}$$

where

$\rho(\mathbf{x})$ = density of receptors at point $\mathbf{x} = (x,y)$
$c(\mathbf{x})$ = concentration increase at $\mathbf{x}$ due to Q
f_{CR} = slope of dose-response or concentration-response (CR) function

The slope of the CR function states the incremental number of cases (e.g., hospitalizations) per concentration increment. Here we assume that f_{CR} has a constant value independent of $\mathbf{x}$.

It is instructive to relate the concentration $c(\mathbf{x})$ to the depletion rate of the pollutant. There are essentially three mechanisms by which an air pollutant can disappear from the atmosphere (Seinfeld and Pandis 1998):

a. Dry deposition (uptake at the earth's surface by soil, water, or vegetation)
b. Wet deposition (absorption into droplets, removed by precipitation)
c. Decay or transformation (e.g., transformation of SO_2 to $(NH_4)_2SO_4$)

When evaluating the damage of a primary pollutant, this pollutant is no longer counted in the equation once it has been transformed; rather from that point on, a different CR function comes into play for the secondary pollutant.

The dry deposition rate is proportional to the concentration $c(\mathbf{x})$ at the earth's surface, and it is customarily written in the form

$$F_{\text{dry}}(\mathbf{x}) = k_{\text{dry}}\, c(\mathbf{x}) \tag{16.6.33}$$

where

$F_{\text{dry}}(\mathbf{x})$ = deposition flux [in kg/(m²·s)]

k_{dry} = dry deposition velocity [m/s]

Wet deposition and decay or transformation can likewise be characterized in terms of fluxes $F_{\text{wet}}(\mathbf{x})$ and $F_{\text{trans}}(\mathbf{x})$, defined as the rate at which the pollutant is removed by these mechanisms per m^2 (horizontal surface area) and per second. Now let us define a "depletion velocity" $k(\mathbf{x})$, in units m/s, as ratio of the total depletion flux:

$$F(\mathbf{x}) = F_{\text{dry}}(\mathbf{x}) + F_{\text{wet}}(\mathbf{x}) + F_{\text{trans}}(\mathbf{x}) \tag{16.6.34}$$

and the surface concentration $c(\mathbf{x})$ as

$$k(\mathbf{x}) = F(\mathbf{x})/c(\mathbf{x}) = k_{\text{dry}}(\mathbf{x}) + k_{\text{wet}}(\mathbf{x}) + k_{\text{trans}}(\mathbf{x}). \tag{16.6.35}$$

Using $F(\mathbf{x})$ and $k(\mathbf{x})$ we can write the damage in the form

$$D = f_{CR} \int dx \int dy\, \rho(\mathbf{x})\, F(\mathbf{x})/k(\mathbf{x}) \tag{16.6.36}$$

Let us now consider a situation where $k(\mathbf{x})$ are $\rho(\mathbf{x})$ are independent of $\mathbf{x}$. With uniform receptor density $\rho(\mathbf{x}) = \rho_{\text{uni}}$ and uniform depletion velocity $k(\mathbf{x}) = k_{\text{uni}}$, the integral in Equation 16.6.35 is simply

$$D = D_{\text{uni}} = \frac{f_{CR}\rho_{\text{uni}}}{k_{\text{uni}}} Q \tag{16.6.37}$$

because, averaged over time, the surface integral of the depletion flux equals the emission

$$Q = \int dx \int dy\, F(\mathbf{x}) \tag{16.6.38}$$

by conservation of matter. This equation can readily be generalized to secondary pollutants. We shall refer to Equation 16.6.37 as the *uniform world model (UWM)*.

As an illustration we calculate D_{uni} for mortality due to SO_2, with f_{CR} = 5.34E-06 YOLL/(pers·yr·µg/m³) (Sunyer et al. 1996). By fitting EcoSense dispersion data we have found a depletion velocity $k = 0.0073$ m/s for SO_2. Inserting these numbers into Equation 16.6.37 with the regional average population density ρ = 8.0E-5 person/m² we obtain for $Q = 10^6$ kg/yr = 3.17E07 µg/s

$$D_{\text{uni}} = \frac{5.34\times10^{-6}\ \text{YOLL}/\left(\text{person}\cdot\text{yr}\cdot\mu\text{g}/\text{m}^3\right)\times 8.0\times10^{-5}\ \text{person}/\text{m}^3}{0.0073\ \text{m/s}} \times 3.17\times10^{7}\ \mu\text{g/s} = 1.86\ \text{YOLL/yr}$$

This is shown as the horizontal line in Figure 16.6.7. It lies right in the middle of the curves for the five sites.

Even though the assumption $k(\mathbf{x}) = k_{\text{uni}}$ may not appear very realistic, especially near a point source, the sensitivity to deviations from uniformity is surprisingly small. The reason is that with tall stacks much of the total impact occurs in regions sufficiently far from the source where the pollutant is fairly well mixed vertically in the PBL, and variations of $k(\mathbf{x})$ are not too large. Emission height dependence and deviations from uniformity are most pronounced when the receptors are concentrated near the source. A source near Paris seems like a fairly extreme example because France is highly centralized, with some 20% of its population in Greater Paris. Cordemais, in a semi-rural zone on the Atlantic cost, is an opposite extreme.

Thus it is plausible that these results are fairly representative and that the UWM can be a useful first estimate, good to an order of magnitude. If one wants typical results for public policy, without being able to evaluate each and every site, D_{uni} seems as good a choice as any — and it has the advantage of being simple and transparent. Spadaro (1999 and additional calculations) and Spadaro and Rabl (2002) have compared the UWM with the results of detailed site-specific calculations for about 100 installations in many countries of Europe, as well as China, Thailand, and Brazil; the detailed calculations were done with the EcoSense software (Krewitt et al. 1995) of the ExternE Project series (1998). They found UWM to be so close to the average that it can be recommended for the calculation of typical values for emissions from tall stacks, more than about 50 m; for specific sites the agreement is usually within a factor of two to three. For ground-level emissions in cities, the impact can be much larger than UWM because of the combination of high receptor densities with the high concentrations near ground-level sources, but simple estimates can still be obtained by applying correction factors to UWM (Spadaro and Rabl 2002).

Analysis of Uncertainties

An analysis of uncertainties begins with a detailed examination of the uncertainties of each of the steps of the impact pathway analysis. However, by contrast to the relatively small uncertainties and normal (Gaussian) frequency distributions typically encountered in science and engineering, the uncertainties in this field are so large that a conventional error analysis is not appropriate. To obtain the uncertainty of the damage cost, the classic approach is a Monte Carlo calculation. One chooses a specific set of values for each of the uncertain input parameters of the impact pathway analysis and calculates the corresponding damage cost. This process is repeated many times, each time choosing the input parameters according to their respective probability distributions. Thus one obtains the distribution of the damage cost estimates. Obviously this procedure requires an extremely large number of computations.

As much simpler alternative an approximate method has been developed by Rabl and Spadaro (1999). It is an analytic approach based on the fact that the UWM of Equation 16.6.37 is a product of the input parameters, and therefore the logarithm of the damage cost is the sum of the logarithms of the input parameters. The standard deviation of a sum is the square root of the sum of the standard deviations of summands, for any distribution of the individual uncertainties, no matter how wide. Thus it is straightforward for the UWM to obtain the standard deviation of the logarithm of the damage cost; it is called the *geometric standard deviation*. Furthermore, the central limit theorem says that the distribution of a sum approaches a Gaussian in the limit where the number of terms becomes large, regardless of the distributions of the individual summands. In practice the distribution of the sum is close to normal even for a small number of terms, except when the widest distributions are far from normal.

A variable x is said to have a lognormal distribution if the variable $\ln(x)$ has a Gaussian distribution, in other words, if it is normal on a logarithmic scale. Thus one can conclude that the distribution of damage costs is approximately lognormal, unless the widest distributions of the input parameters are far from normal. A closer look at the uncertainties of the input parameters (Rabl and Spadaro 1999) shows that the conditions for lognormality of the damage cost are fairly well satisfied. Thus one can obtain a very simple approximate estimate of the uncertainties.

Analogous to the ordinary normal distribution, which is characterized by two parameters, the mean and the standard deviation, the lognormal distribution can be characterized by the geometric mean and the geometric standard deviation s_G. For this distribution the geometric mean is equal to the median: half of the distribution is above, the other half below the median. The geometric standard deviation has a simple interpretation in terms of multiplicative confidence intervals: for a lognormal distribution 68% of the values are within the interval $(1/s_G, s_G)$; likewise, 95% are within the interval $[(1/s_G)^2, (s_G)^2]$. Note, however, that these values are centered around the median rather than the mean; the lognormal distribution is not symmetric. For impacts of primary air pollutants with relatively well-determined dose-response functions, for example, mortality due to particulates, s_G may be as small as 3. For other impacts, such as cancers due to dioxins, the uncertainties could be an order of a magnitude or even more.

When we compare these two methods for uncertainty analysis, the Monte Carlo method has the advantage of being able to take into account arbitrary distributions of the component uncertainties, but it is computationally intensive and the result is "black box": one does not learn how important each of the component uncertainties is or how the result would change if a component uncertainty changes, unless one performs such a large number of simulations that it becomes difficult to "see the forest for the trees." The lognormal method with the UWM is approximate, but simple and fully transparent; its validity can be improved by calibrating it with the Monte Carlo results. Thus one can combine the best features of the two approaches.

One should note that technical or scientific uncertainties (e.g., uncertainties of emitted quantities or of dose-response functions) are not the only ones. For long-term impacts, such as cancers caused by radioactive waste, one needs to make assumptions about scenarios for the future: what quantities of radionuclides will leak into the environment and how many people will be affected by them. For the estimation of damage costs, there is also the matter of policy/ethical choice, e.g., about discount rate and value of human life.

Results

The impact pathway analysis yields the damage costs per kg of pollutant. Results for pollutants emitted by power plants under typical European conditions are shown in Table 16.6.1. Some indication of the variability with site and stack conditions is given in the notes under the table.

Multiplying the cost per kg by the emission rates in gm/kWh, one readily finds the cost per kWh. Results are plotted in Figure 16.6.8.

TABLE 16.6.1 Typical Damage Costs per kg of Pollutant Emitted by Power Plants in Europe

Pollutant	Impact	Cost [a], ∈/kg
PM10 (primary)	Mortality and morbidity	15.4
SO_2 (primary)	Crops, materials	0.3
SO_2 (primary)	Mortality and morbidity	0.3
SO_2 (via sulfates)	Mortality and morbidity	9.95
NO_2 (primary)	Mortality and morbidity	Small
NO_2 (via nitrates)	Mortality and morbidity	14.5
NO_2 (via O_3)	Crops	0.35
NO_2 (via O_3)	Mortality and morbidity	1.15
VOC (via O_3)	Crops	0.2
VOC (via O_3)	Mortality and morbidity	0.7
CO (primary)	Morbidity	0.002
As (primary)	Cancer	171
Cd (primary)	Cancer	20.9
Cr (primary)	Cancer	140
Ni (primary)	Cancer	2.870
Dioxins, TEQ	Cancer	1.85×10^7
CO_2	Global warming	0.029

[a] Variation with site and stack conditions (stack height, exhaust temperature, exhaust velocity):

- No variation for CO_2;
- Weak variation for dioxin (non-inhalation pathways): factor of 0.7 to 1.5;
- Weak variation for secondary pollutants: factor of 0.5 to 2.0;
- Strong variation for primary pollutants: factor of 0.5 to 5 for site, 0.6 to 3 for stack conditions (up to 15 for ground-level emissions in big city).

Source: [Spadaro and Rabl 1999, Spadaro 1999]

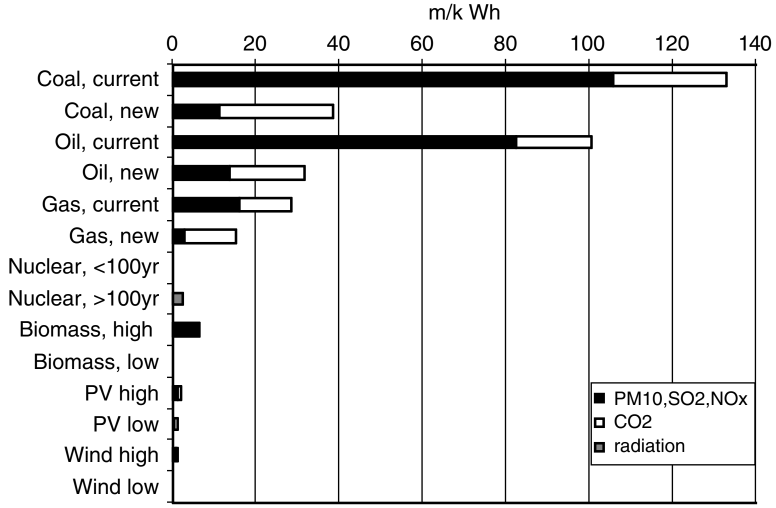

FIGURE16.6.8 Comparison of damage costs, for fuel chains in the European Union (EU), with ∈/kg of Table 16.6.1. For fossil fuel chains "current" corresponds to emissions in the EU and the U.S. during the mid-1990s, "new" to emission limits imposed by the new EU Directive effective after 2000. For renewables "high" and "low" indicate typical range of estimates of ExternE (1998). For nuclear only a single technology is shown (French, with reprocessing), but costs are separated into near (before 100 yr) and far (after 100 yr) future. For comparison production costs of base load electricity in the EU and U.S. are in the range of 25 to 50 m∈/kWh.

Defining Terms

Aerosol: Small solid particle or liquid droplet suspended in the air.

Anthropogenic: Man-made.

Deterministic: Dealing with cause and effect.

Ensemble average: Theoretical average, that is, the value that could be expected as the average from an infinite number of realizations.

Global warming: The warming of the earth as a result of the atmosphere, which traps solar radiation. Currently, the term *global warming* is used to denote the temperature increase due to carbon dioxide, methane, and other greenhouse gases.

Greenhouse gases: Carbon dioxide, methane, and other gases resulting from human activities that increase the amount of solar radiation trapped by the atmosphere.

Numerical advection errors: Numerical errors generated by finite-difference solutions of transport terms using a Eulerian grid model.

Organic compounds: Chemical species containing one or more carbon atoms.

Photochemical: Chemical reactions influenced by light.

Photolysis: Chemical decomposition by the action of light.

Planetary boundary layer (PBL): The atmospheric layer that is affected by the momentum and heat fluxes generated by the earth's surface (typically, the first 500–1000 m of the atmosphere).

PM_d: Particulate matter with a diameter smaller than d μm.

Stratospheric: Related to the stratosphere, the portion of the atmosphere approximately between 10 and 50 km above the ground.

Tropospheric: Related to the troposphere, the lower level of the atmosphere approximately from the surface to 10 km above.

VOC: Volatile organic compounds.

Wind shear: The change in wind speed and direction as a function of height.

16.7 Global Climate Change

John Firor

It has now been convincingly demonstrated that the average temperature of Earth's surface air has increased substantially in the past hundred years. The cause of this warming is frequently attributed to the release of heat-trapping gases by human activities resulting in heat that would have escaped back to space being retained near the surface of Earth. This process is called the "Greenhouse effect" and the gases are referred to as "Greenhouse gases."

The original warming conclusions were based on records from widely distributed thermometers that had been read daily for many years. These conclusions were subsequently confirmed by a number of independent measurements, including measured warming of the sea surface and land areas far from cities; melting of many glaciers worldwide; and temperatures measured at various depths in abandoned oil wells and other deep holes. For earlier periods, proxies of temperature are available, such as data from isotopic ratios in ice recovered from various depths in Greenland and Antarctic ice; pollen grains recovered from depths of sediments on lake bottoms indicating what plants grew nearby; dates of wine grape harvests; and letters and diaries reporting dates of lake or river freezing or melting and other relevant events.

Long before society began to add greenhouse gases to the air, appreciable amounts of some greenhouse gases were naturally appearing in the air. Also in the late eighteenth century the infrared absorption of carbon dioxide was measured and Jean-Baptiste Fourier — a name familiar to all math students — postulated in 1847 that if carbon dioxide in the atmosphere could absorb energy in the form of infrared light, it would keep the lower atmosphere and the surface of Earth warmer than it would otherwise be (Jones and Henderson-Sellers 1990). Fourier did not include in his speculation an important greenhouse gas that had not yet been recognized as such: water vapor. On average there is so much of this gas in the air, supplied daily by evaporation from oceans, lakes, and rivers, that the total effect of this ancient, natural greenhouse effect is very large. Without it Earth's surface would have been about 33°C colder, and it seems unlikely that the current set of plants and animals would have evolved. This well-established fact leads naturally to the idea that adding more greenhouse gases to the air will make the climate even warmer. Figure 16.7.1 shows that additional amounts of two important greenhouse gases are indeed being added to the atmosphere at the same time that global population is growing, increasing pressure for the emission of greenhouse gases. Both of these increases began with the Industrial Revolution in the 1800s when coal, from which methane is known to emerge as coal is mined, began to be widely used as a fuel.

Figure 16.7.2 shows the increase in global average surface temperature for the period 1860 to 1995, resulting from these additions, a change that gives support to the idea that adding more greenhouse gases will lead to warming. Figure 16.7.3 shows the surface temperature of the Northern Hemisphere during the past millennium deduced from proxy evidence. This graph indicates that, except for a small cooling from 1500 to about 1850, the temperature was fairly stable, until the time of the Industrial Revolution and the start of major coal burning, when it began to rise sharply.

In recent times the theory of the greenhouse effect, including the effect of the additional heat trapping gases released by human activity, has been explored with the use of complex numerical models using super computers. These models trace energy from the sun, in the form of visible light that penetrates the atmosphere and warms the surface. The warmed surface then tries to release this extra heat to space.

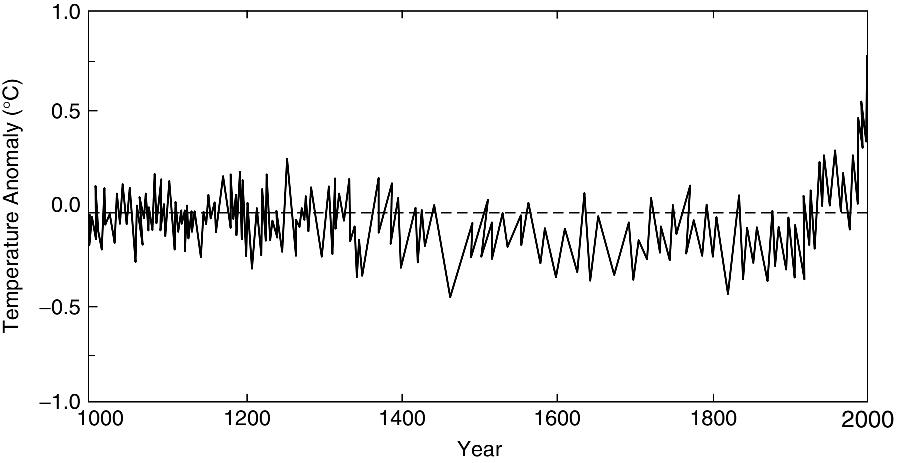

FIGURE 16.7.1 Increases in the atmospheric concentrations of two important greenhouse gases released by human activity and global population increase for 11,000-1993. Drawn from various published data.

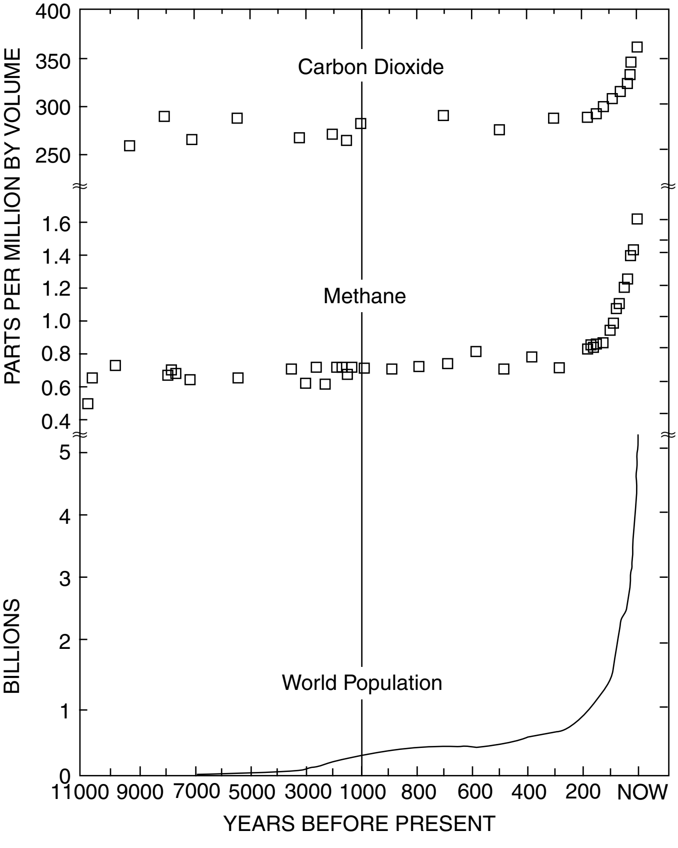

FIGURE 16.7.2 Global average near surface temperature 1860–1995. The black dots are annual average temperatures; the solid line is the running average to smooth out year-to-year variations. fluctuations. Plotted from data assembled and corrected by Phil Jones, Climate Research Unit, University of East Anglia, in the UK. Original numbers available at http://www.cru.uea.ac.uk.

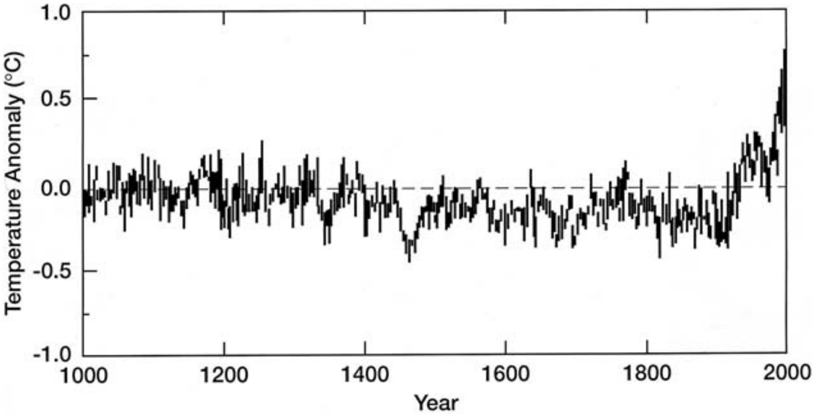

FIGURE 16.7.3 Northern Hemisphere surface temperature during the last millennium deduced from proxy data. The dashed line is along the average temperature 1902–1980. Data after 1990 represent thermometer measurements, as shown in Figure 16.7.1. Chart redrawn from Mann, M.E., Bradley, R.S., and Hughes, M.K., *Geophys. Res. Lets*, 26:729-62, 1999.

Earth's surface is too cool to emit visible light that would easily escape; the emission is of longer wavelength infrared radiation that is absorbed by water vapor, carbon dioxide, methane, and nitrous oxide, ozone, CFCs, and other, less important, species. The calculation concerning the total effect of this process must also include the effect of particles such as soot, sulfates, and others that can either absorb radiation or reflect it. Finally, allowance must be made for the small changes in the intensity of sunlight reaching the top of Earth's atmosphere, changes that in recent times have been measured by instruments carried above the atmosphere on satellites. Correctly simulating all of these interactions, as well as the complex motions of the atmosphere and oceans, forces the vast complexity of the climate change models (Washington and Parkinson 1986). Progress in climate change science is most comprehensibly described by the Intergovernmental Panel on Climate Change (IPCC), created by the World Meteorological Organization and the United Nations Environment Program in 1998, which has issued reviews at five-year internals: 1990, 1995, 2001, each titled Climate Change (*year*), for example, Climate Change 2001 for the most recent one.

These models rather successfully predict the observed average warming of Earth in the past century. This agreement supports the hope that the models will be useful, if not exactly precise, in projecting future climates under a variety of assumptions about future changes in atmospheric composition. Such projections are needed since a major change in climate would have many impacts on society for which we would wish to be prepared.

Water vapor in the air, except locally, is not controlled by human activity. Other gases — carbon dioxide, for example — are tightly coupled to human activity and hence possibly under control of national governments. Good projections of future climate conditions are also needed to guide attempts to ameliorate the most harmful changes.

It should be noted that if all human-induced emissions ceased tomorrow, the climate would continue to warm for decades and sea levels would continue to rise for two thousand years or more, both responding to the fact that some greenhouse gases remain in the air for a hundred or a thousand years or more, continuing to warm Earth's surface. So reductions in emissions cannot prevent all warming but can prevent us from having to deal with a much larger set of climate changes than we are already committed to.

The extra greenhouse gases have, by 2001, increased the average temperature of the global surface air by about .06°C and increased total precipitation and more intense heavy precipitation events in Northern Hemisphere countries. The climate change has also warmed, and thereby expanded, ocean water and melted some glacial and polar ice, the two effects leading to a rise of sea levels by 10 to 25 cm. Assuming "business as usual" emissions of greenhouse gases, models project an additional increase in sea level in the range of 20 to 86 cm by 2100, and a further temperature increase of about 2.5°C (IPCC 2001).

The greenhouse gases capable of being controlled by human action arise from various activities. Carbon dioxide is emitted from the use of fossil fuel — especially coal, with smaller contributions from deforestation and cement manufacturing. Globally, emissions of CO_2 are approximately 25,000 million metric tons a year (MMT/yr). Methane emerges from any wet place in which organic matter decays without enough oxygen present, such as rice cultivation, enteric fermentation in cattle and termites, and landfills. Deforestation, oil wells, coal mining, and leaking natural gas installations also contribute to methane emissions. Global methane emissions are estimated to be around 540, MMT/yr. CFCs and related compounds are entirely human produced, and the Vienna Convention for the Protection of the Ozone Layer and the subsequent Montreal Protocol and its revisions already control the production of these chemicals. Nitrous oxide comes largely from the use of fertilizer containing nitrogen, and the manufacturing of certain industrial acids. These sources provide N_2O emissions of about 5 MMT/yr. Ozone is not normally emitted but is created when sunlight acts on methane, non-methane hydrocarbons, and carbon monoxide in the air, triggering reactions with oxides of nitrogen to produce ozone. Ozone concentrations average about 35ppb (Schimel et al 1996, and IPCC 1995).

Atmospheric concentrations of these gases are measured in parts per million ppm, parts per billion ppb, or parts per trillion ppt. In 1998 the concentrations were CO_2 367 ppm and CH_4 1693 ppb. A number of CFC-related compounds contribute their heat-trapping ability, and, as mentioned earlier, they are all being controlled so that the concentrations are steady or decreasing. The largest CFC concentration in 1998 was that of CFC-12 at 530 ppt. Even with such small concentrations, these chemicals add to the greenhouse effect because each molecule of CFC-12 absorbs several thousand times as much infrared radiation as each molecule of CO_2. Sulfur dioxide emissions are also an important contributor to climate calculations. In the air, sulfur reacts to create sulfate particles that reflect sunlight and decrease the rate of climate warming. These particles only remain in the air for a week or two, but they are rapidly replaced by emissions from coal-burning power plants and the smelting of sulfur containing ores. Global emissions of sulfur dioxide are less well known than carbon dioxide emissions, but may range above 40,000 MMT/yr (WRI 2000).

A major international agreement — the Framework Convention on Climate Change — was negotiated at the United Nations meeting in Rio in 1992 and was ratified by 186 countries by 1995, including the United States. The ultimate objective of the agreement was described as

> …stabilization of the greenhouse concentrations in the atmosphere at a level that would prevent dangerous anthropogenic interference with the climate system. Such a level should be achieved within a time-frame sufficient to allow ecosystems to adapt naturally to climate change, to ensure that food production is not threatened and to enable economic development to proceed in a sustainable manner.

Developed countries additionally agreed to attempt to reduce their carbon dioxide emissions back to 1990 levels by the year 2000, but only England, Germany, and Russia succeeded. The U.S., the largest emitter of greenhouse gases, made little attempt to reduce its emissions, and later, when a protocol was adopted specifying the amount each developed country would be expected to reduce, the U.S. withdrew entirely from the agreement and pronounced that doing anything to make reductions would ruin the economy. Many other countries, however, continued to move toward making this treaty and protocol effective, and some have instituted steps to reduce their emissions even before the protocol is finally ratified. But the extent to which countries will succeed in reducing emissions before the climate changes being induced become very serious is still unknown.

The various claims that the costs of reducing emissions would be excessive have been somewhat softened by a survey of 50 large businesses that had reduced their energy use voluntarily using existing technologies. These companies found that the savings from lower energy bills and incidental improvements usually repaid their investment in one year and continued to produce increased profits indefinitely. Also, a review of the models showing large costs revealed that these calculations assumed “worst case” conditions, omitting considerations that would have reduced the costs (Repetto, D. and Austin, N. 1997).

17.1 Engineering Economic Decisions

Decisions made during the engineering design phase of product development determine the majority (some say 85%) of the costs of manufacturing that product. Thus, a competent engineer in the 21st century must have an understanding of the principles of economics as well as engineering. This chapter examines the most important economic concepts that should be understood by engineers.

---

[*] Department of Industrial & Systems Engineering, Auburn University, Auburn, AL 36849. Sections 17.1 through 17.6 based on *Contemporary Engineering Economics,* 2nd edition, by Chan S. Park, Addison-Wesley Publishing Company, Reading, MA, 1997.

Engineers participate in a variety of decision-making processes, ranging from manufacturing to marketing to financing decisions. They must make decisions involving materials, plant facilities, the in-house capabilities of company personnel, and the effective use of capital assets such as buildings and machinery. One of the engineer's primary tasks is to plan for the acquisition of equipment (fixed asset) that will enable the firm to design and produce products economically. These decisions are called *engineering economic decisions.*

17.2 Establishing Economic Equivalence

A typical engineering economic decision involves two dissimilar types of dollar amounts. First, there is the investment, which is usually made in a lump sum at the beginning of the project, a time that for analytical purposes is called today, or time 0. Second, there is a stream of cash benefits that are expected to result from this investment over a period of future years.

In such a fixed asset investment funds are committed today in the expectation of earning a return in the future. In the case of a bank loan, the future return takes the form of interest plus repayment of the principal. This is known as the *loan cash flow.* In the case of the fixed asset, the future return takes the form of cash generated by productive use of the asset. The representation of these future earnings along with the capital expenditures and annual expenses (such as wages, raw materials, operating costs, maintenance costs, and income taxes) is the *project cash flow.* This similarity between the loan cash flow and the project cash flow brings us an important conclusion—that is, first we need to find a way to evaluate a money series occurring at different points in time. Second, if we understand how to evaluate a loan cash flow series, we can use the same concept to evaluate the project cash flow series.

Interest: The Cost of Money

Money left in a savings account earns interest so that the balance over time is greater than the sum of the deposits. In the financial world, money itself is a commodity, and like other goods that are bought and sold, money costs money. The cost of money is established and measured by an *interest rate,* a percentage that is periodically applied and added to an amount (or varying amounts) of money over a specified length of time. When money is borrowed, the interest paid is the charge to the brrower for the use of the lender's property; when money is loaned or invested, the interest earned is the lender's gain from providing a good to another. *Interest*, then, may be defined as the cost of having money available for use.

The operation of interest reflects the fact that money has a time value. This is why amounts of interest depend on lengths of time; interest rates, for example, are typically given in terms of a percentage per year. This principle of the time value of money can be formally defined as follows: the economic value of a sum depends on when it is received. Because money has earning power over time (it can be put to work, earning more money for its owner), a dollar received today has a greater value than a dollar received at some future time.

The changes in the value of a sum of money over time can become extremely significant when we deal with large amounts of money, long periods of time, or high interest rates. For example, at a current annual interest rate of 10%, $1 million will earn $100,000 in interest in a year; thus, waiting a year to receive $1 million clearly involves a significant sacrifice. In deciding among alternative proposals, we must take into account the operation of interest and the time value of money to make valid comparisons of different amounts at various times.

The Elements of Transactions Involving Interest

Many types of transactions involve interest — for example, borrowing or investing money, purchasing machinery on credit — but certain elements are common to all of them:

1. Some initial amount of money, called the *principal* (*P*) in transactions of debt or investment
2. The *interest rate* (*i*), which measures the cost or price of money, expressed as a percentage per period of time
3. A period of time, called the *interest period* (or *compounding period*), that determines how frequently interest is calculated
4. The specified length of time that marks the duration of the transaction and thereby establishes a certain *number of interest periods* (*N*)
5. A *plan for receipts or disbursements* (A_n) that yields a particular cash flow pattern over the length of time (for example, we might have a series of equal monthly payments [A] that repay a loan)
6. A *future amount of money* (F) that results from the cumulative effects of the interest rate over a number of interest periods

Cash Flow Diagrams

It is convenient to represent problems involving the time value of money in graphic form with a cash flow diagram (see Figure 17.2.1), which represents time by a horizontal line marked off with the number of interest periods specified. The cash flows over time are represented by arrows at the relevant periods: upward arrows for positive flows (receipts) and downward arrows for negative flows (disbursements).

End-of-Period Convention

In practice, cash flows can occur at the beginning or in the middle of an interest period, or at practically any point in time. One of the simplifying assumptions we make in engineering economic analysis is the *end-of-period convention*, which is the practice of placing all cash flow transactions at the end of an interest period. This assumption relieves us of the responsibility of dealing with the effects of interest within an interest period, which would greatly complicate our calculations.

Compound Interest

Under the compound interest scheme, the interest in each period is based on the total amount owed at the end of the previous period. This total amount includes the original principal plus the accumulated interest that has been left in the account. In this case, you are in effect increasing the deposit amount by

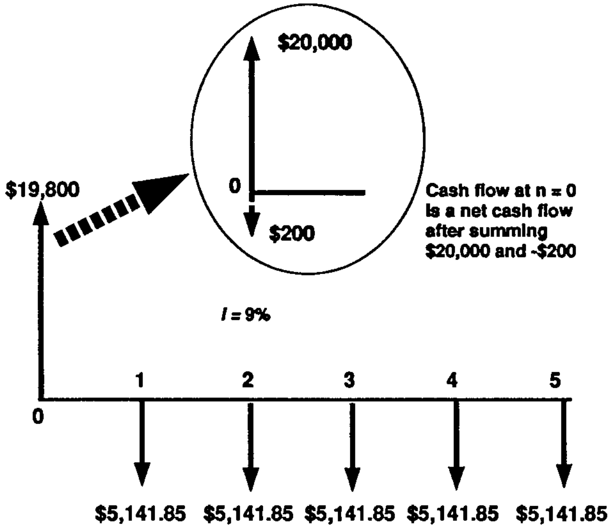

FIGURE 17.2.1 A cash flow diagram for a loan transaction — borrow $20,000 now and pay off the loan with five equal annual installments of $5,141.85. After paying $200 for the loan origination fee, the net amount of financing is $19,800. The borrowing interest rate is 9%.

the amount of interest earned. In general, if you deposited (invested) P dollars at interest rate i, you would have P + iP = P(1 + i) dollars at the end of one period. With the entire amount (principal and interest) reinvested at the same rate i for another period, you would have, at the end of the second period,

$$
\begin{aligned}
P(1+i)+i\left[P(1+i)\right] &= P(1+i)(1+i) \\
&= P(1+i)^2
\end{aligned}
$$

This interest-earning process repeats, and after N periods, the total accumulated value (balance) F will grow to

$$F = P(1+i)^N \tag{17.2.1}$$

Equivalence Calculations

Economic equivalence refers to the fact that a cash flow — whether it is a single payment or a series of payments — can be said to be converted to an *equivalent* cash flow at any point in time; thus, for any sequence of cash flows, we can find an equivalent single cash flow at a given interest rate and a given time.

Equivalence calculations can be viewed as an application of the compound interest relationships developed in Equation 17.2.1. The formula developed for calculating compound interest, $F = P(1 + i)^N$, expresses the equivalence between some present amount, P, and a future amount, F, for a given interest rate, i, and a number of interest periods, N. Therefore, at the end of a 3-year investment period at 8%, $1000 will grow to

$$\$1000(1+0.08)^3 = \$1259.71$$

Thus at 8% interest, $1000 received now is equivalent to $1,25l9.71 received in 3 years and we could trade $1000 now for the promise of receiving $1259.71 in 3 years. Example 17.2.1 demonstrates the application of this basic technique.

Example 17.2.1 — Equivalence

Suppose you are offered the alternative of receiving either $3000 at the end of 5 years or P dollars today. There is no question that the $3000 will be paid in full (no risk). Having no current need for the money, you would deposit the P dollars in an account that pays 8% interest. What value of P would make you indifferent in your choice between P dollars today and the promise of $3000 at the end of 5 years from now?

Discussion

Our job is to determine the present amount that is economically equivalent to $3000 in 5 years, given the investment potential of 8% per year. Note that the problem statement assumes that you would exercise your option of using the earning power of your money by depositing it. The "indifference" ascribed to you refers to economic indifference; that is, within a marketplace where 8% is the applicable interest rate, you could trade one cash flow for the other.

Solution

From Equation (17.2.1), we establish

$$\$3000 = P(1+0.08)^5$$

Rearranging to solve for P,

$$P = \$3000/(1+0.08)^5 = \$2042$$

Comments

In this example, it is clear that if P is anything less than \$2042, you would prefer the promise of \$3000 in 5 years to P dollars today; if P were greater than \$2042, you would prefer P. It is less obvious that at a lower interest rate, P must be higher to be equivalent to the future amount. For example, at $i = 4\%$, $P = \$2466$.

Interest Formulas

In this section is developed a series of interest formulas for use in more complex comparisons of cash flows. It classifies four major categories of cash flow transactions, develops interest formulas for them, and presents working examples of each type.

Single Cash Flow Formulas

We begin our coverage of interest formulas by considering the simplest cash flows: single cash flows. Given a present sum P invested for N interest periods at interest rate i, what sum will have accumulated at the end of the N periods? You probably noticed quickly that this description matches the case we first encountered in describing compound interest. To solve for F (the future sum) we use Equation (17.2.1):

$$F = P(1+i)^N = P(F/P,i,N)$$

Because of its origin in compound interest calculation, the factor (F/P, i, N), which is read as "find F, given P, i, and N" is known as the *single payment compound amount factor*. Like the concept of equivalence, this factor is one of the foundations of engineering economic analysis. Given this factor, all the other important interest formulas can be derived. This process of finding F is often called the compounding process. (Note the time-scale convention. The first period begins at $n = 0$ and ends at $n = 1$.) Thus, in the preceding example, where we had $F = \$1000(1.08)^3$, we can write $F = \$1000(F/P, 8\%, 3)$. We can directly evaluate the equation or locate the factor value by using the 8% interest table* and finding the factor of 1.2597 in the F/P column for $N = 3$.

Finding present worth of a future sum is simply the reverse of compounding and is known as *discounting process*. In Equation (17.2.1), we can see that if we were to find a present sum P, given a future sum F, we simply solve for P.

$$P = F\left[\frac{1}{(1+i)^N}\right] = F(P/F,i,N) \tag{17.2.2}$$

The factor $1/(1 + i)^N$ is known as the *single payment present worth factor* and is designated (P/F, i, N). Tables* have been constructed for the P/F factors for various values of i and N. The interest rate i and the P/F factor are also referred to as *discount rate* and *discounting factor*, respectively. Because using the interest tables is often the easiest way to solve an equation, this factor notation is included for each of the formulas derived in the following sections.

A Stream of Cash Flow Series

A common cash flow transaction involves a series of disbursements or receipts. Familiar situations such as car loans and insurance payments are examples of series payments. Payments of car loans and insurance bills typically involve identical sums paid at regular intervals. However, when there is no clear pattern of payment amounts over a series, one calls the transaction an *uneven cash-flow series*.

---

* All standard engineering economy textbooks (such as *Contemporary Engineering Economics* by C. S. Park, Addison Wesley, 1997) provide extensive sets of interest tables. Or you can obtain such interest tables on a World Wide Web site at http://www.eng.auburn.edu/-park/cee.html, which is a textbook web site for *Contemporary Engineering Economics.*

The present worth of any stream of payments can be found by calculating the present value of each individual payment and summing the results. Once the present worth is found, one can make other equivalence calculations, such as calculating the future worth by using the interest factors developed in the previous section.

Example 17.2.2 — Present Value of an Uneven Series by Decomposition into Single Payments

Wilson Technology, a growing machine shop, wishes to set aside money now to invest over the next 4 years in automating their customer service department. They now earn 10% on a lump sum deposited, and they wish to withdraw the money in the following increments:

Year 1: $25,000 to purchase a computer and data base software designed for customer service use
Year 2: $3000 to purchase additional hardware to accommodate anticipated growth in use of the system
Year 3: No expenses
Year 4: $5000 to purchase software upgrades

How much money must be deposited now to cover the anticipated payments over the next 4 years?

Discussion

This problem is equivalent to asking what value of P would make you indifferent in your choice between P dollars today and the future expense stream of ($25,000, $3000, $0, $5000). One way to deal with an uneven series of cash flows is to calculate the equivalent present value of each single cash flow and sum the present values to find P. In other words, the cash flow is broken into three parts as shown in Figure 17.2.2.

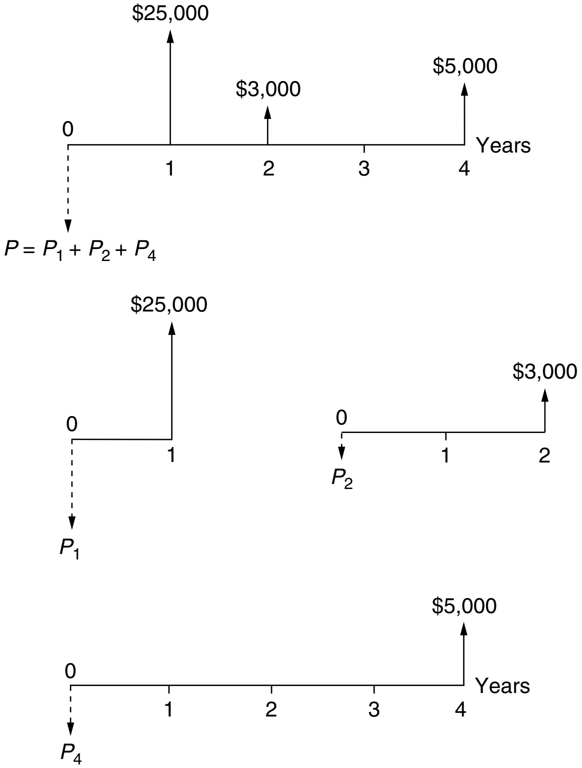

FIGURE 17.2.2 Decomposition of uneven cash flow series into three single-payment transactions. This decomposition allows us to use the single-payment present worth factor.

Solution

$$
\begin{aligned}
P &= \$25{,}000(P/F,10\%,1) + \$3000(P/F,10\%,2) + \$5000(P/F,10\%,4) \\
&= \$28{,}622
\end{aligned}
$$

Cash Flow Series with a Special Pattern

Whenever one can identify patterns in cash flow transactions, one may use them in developing concise expressions for computing either the present or future worth of the series. For this purpose, we will classify cash flow transactions into three categories: (1) equal cash flow series, (2) linear gradient series, and (3) geometric gradient series. To simplify the description of various interest formulas, we will use the following notation:

1. Uniform Series: Probably the most familiar category includes transactions arranged as a series of equal cash flows at regular intervals, known as an *equal-payment series* (or *uniform series*) (Figure 17.2.3a). This describes the cash flows, for example, of the common installment loan contract, which arranges for the repayment of a loan in equal periodic installments. The equal cash flow formulas deal with the equivalence relations of P, F, and A, the constant amount of the cash flows in the series.
2. Linear Gradient Series: While many transactions involve series of cash flows, the amounts are not always uniform: yet they may vary in some regular way. One common pattern of variation occurs when each cash flow in a series increases (or decreases) by a fixed amount (Figure 17.2.3b). A 5-year loan repayment plan might specify, for example, a series of annual payments that increased by $50 each year. We call such a cash flow pattern a *linear gradient series* because its cash flow diagram produces an ascending (or descending) straight line. In addition to P, F, and A, the formulas used in such problems involve the constant amount, G, of the change in each cash flow.
3. Geometric Gradient Series: Another kind of gradient series is formed when the series in cash flow is determined, not by some fixed amount like $50, but by some fixed *rate*, expressed as a percentage. For example, in a 5-year financial plan for a project, the cost of a particular raw material might be budgeted to increase at a rate of 4% per year. The curving gradient in the diagram of such a series suggests its name: a *geometric gradient series* (Figure 17.2.3c). In the formulas dealing with such series, the rate of change is represented by a lowercase g.

Table 17.2.1 summarizes the interest formulas and the cash flow situations in which they should be used. For example, the factor notation (F/A, i, N) represents the situation where you want to calculate the equivalent lump-sum future worth (F) for a given uniform payment series (A) over N period at interest rate i. Note that these interest formulas are applicable only when the interest (compounding) period is the same as the payment period. Also in this table we present some useful interest factor relationships. The next two examples illustrate how one might use these interest factors to determine the equivalent cash flow.

Example 17.2.3 — Uniform Series: Find F, Given i, A, N

Suppose you make an annual contribution of $3000 to your savings account at the end of each year for 10 years. If your savings account earns 7% interest annually, how much can be withdrawn at the end of 10 years? (See Figure 17.2.4.)

Solution

$$
\begin{aligned}
F &= \$3000(F/A,7\%,10) \\
&= \$3000(13.8164) \\
&= \$41{,}449.20
\end{aligned}
$$

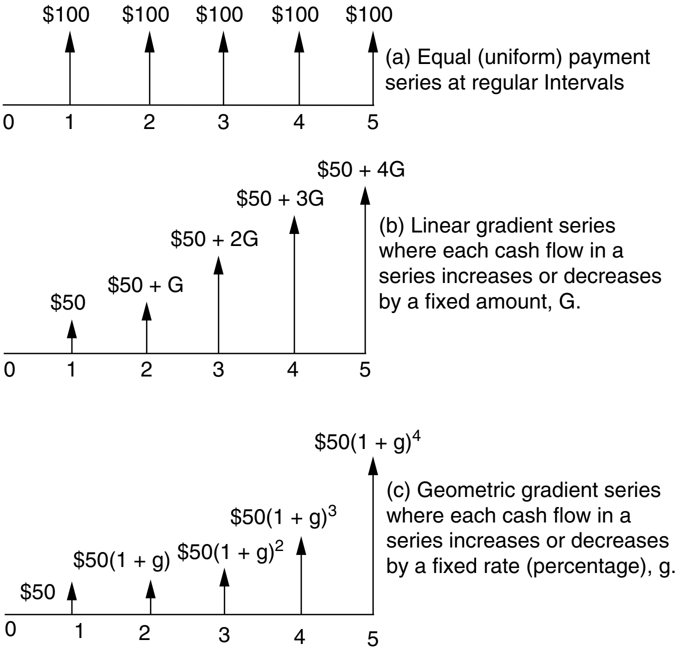

FIGURE 17.2.3 Five types of cash flows: (a) equal (uniform) payment series; (b) linear gradient series; and (c) geometric gradient series.

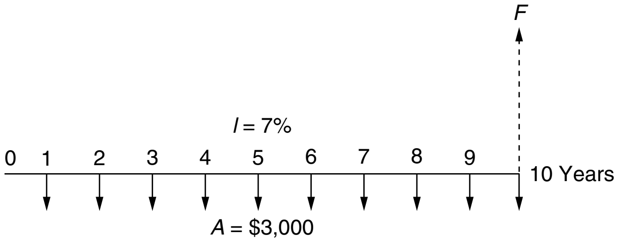

FIGURE 17.2.4 Cash flow diagram (Example 17.2.3).

Example 17.2.4 — Geometric Gradient: Find P, Given A_1, g, i, N

Ansell Inc., a medical device manufacturer, uses compressed air in solenoids and pressure switches in the machines to control the various mechanical movements. Over the years the manufacturing floor has changed layouts numerous times. With each new layout more piping was added to the compressed air delivery system to accommodate the new locations of the manufacturing machines. None of the extra, unused old pipe was capped or removed; thus the current compressed air delivery system is inefficient and fraught with leaks. Because of the leaks in the current system, the compressor is expected to run 70% of the time that the plant is in operation during the upcoming year, which will require 260 kW/hr of electricity at a rate of $0.05/kW-hr. (The plant runs 250 days a year for 24 hr a day.) If Ansell continues to operate the current air delivery system, the compressor run time will increase by 7% per year for the next 5 years due to ever-deteriorating leaks. (After 5 years, the current system cannot meet the plant's compressed air requirement, so it has to be replaced.) If Ansell decides to replace all of the old piping now, it will cost $28,570. The compressor will still run the same number of days; however, it will run 23% less (or 70% (1 – 0.23) = 53.9% usage during the day) because of the reduced air pressure loss. If Ansell's interest rate is 12%, is it worth fixing now?

TABLE 17.2.1 Summary of Discrete Compounding Formulas with Discrete Payments

Flow Type	Factor Notation	Formula	Cash Flow Diagram	Factor Relationship
Single	Compound amount (*F/P, i, N*) Present worth (*P/F, i, N*)	$F = P(1 + i)^N$ $P = F(1 + i)^{-N}$		(*F/P, i, N*) = *i*(*F/A, i, N*) + 1 (*P/F, i, N*) = 1 – (*P/A, i N*)*i*
Equal Payment Series	Compound amount (*F/A, i, N*)	$F = A\left[\frac{(1+i)^N - 1}{i}\right]$		(*A/F, i, N*) = (*A/P, i, N*) – i
	Sinking fund (*A/F, i, N*)	$A = F\left[\frac{i}{(1+i)^N - 1}\right]$		
	Present worth (*P/A, i, N*)	$P = A\left[\frac{(1+i)^N - 1}{i(1+i)^N}\right]$		$(A/P,i,N) = \frac{i}{1-(P/F,i,N)}$
	Capital recovery (*A/P, i, N*)	$A = P\left[\frac{i(1+i)^N}{(1+i)^N - 1}\right]$		
Gradient Series	Uniform gradient Present worth (*P/G, i, N*)	$P = C\left[\frac{(1+i)^N - iN - 1}{i^2(1+i)^N}\right]$		(*F/G, i, N*) = (*P/G, i, N*)(*F/P, i, N*) (*A/G, i, N*) = (*P/G, i, N*)(*A/P, i, N*)
	Geometric gradient Present worth (*P/A*$_1$*, g, i, N*)	$P = \begin{bmatrix} A_1\left[\frac{1-(1+g)^N(1+i)^{-N}}{i-g}\right] \\ \frac{NA_1}{1+i}\ (\text{if}\ i = g) \end{bmatrix}$		(*F/A*$_1$*, g, i, N*) = (*P/A*$_1$*, g, i, N*)(*F/P, i N*)

Tables are constructed for various interest factors and you can obtain such interest tables on a World Wide Web site at http://www.eng.auburn.edu/~park/cee.html, which is a textbook web site for *Contemporary Engineering Economics.*

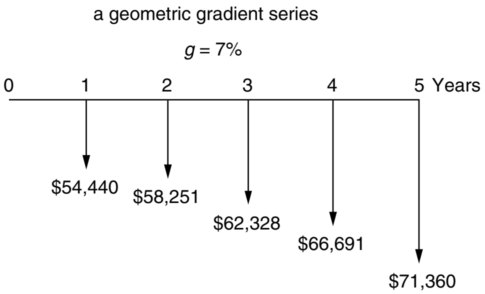

FIGURE 17.2.5 Expected power expenditure over the next 5 years due to deteriorating leaks if no repair is performed (Example 17.2.4).

Solution

- Step 1. Calculate the cost of power consumption of the current piping system during the first year. The power consumption is equal to:

$$\begin{aligned}\text{power cost} &= \%\text{ of day operating} \times \text{days operating per year} \times \text{hours per day}\\ &\quad \times \text{kW/hr} \times \$/\text{kW-hr}\\ &= (70\%) \times (250\ \text{days/year}) \times (24\ \text{hr/day}) \times (260\ \text{kW/hr}) \times (\$0.05/\text{kW-hr})\\ &= \$54{,}440\end{aligned}$$

- Step 2. Each year the annual power cost will increase at the rate of 7% over the previous year's power cost. Then the anticipated power cost over the 5-year period is summarized in Figure 17.2.5. The equivalent present lump-sum cost at 12% for this geometric gradient series is

$$\begin{aligned}P_{Old} &= \$54{,}440\left(P/A_1, 7\%, 12\%, 5\right)\\ &= \$54{,}440\left[\frac{1-(1+0.07)^5(1+0.12)^{-5}}{0.12-0.07}\right]\\ &= \$222{,}283\end{aligned}$$

- Step 3. If Ansell replaces the current compressed air system with the new one, the annual power cost will be 23% less during the first year and will remain at that level over the next 5 years. The equivalent present lump-sum cost at 12% is

$$\begin{aligned}P_{New} &= \$54{,}440(1-0.23)\left(P/A, 12\%, 5\right)\\ &= \$41{,}918.80(3.6048)\\ &= \$151{,}108\end{aligned}$$

- Step 4. The net cost for not replacing the old system now is $71,175 (= $222,283 – $151,108). Since the new system costs only $28,570, the replacement should be made now.

Nominal and Effective Interest Rates

In all our examples in the previous section, we implicitly assumed that payments are received once a year, or annually. However, some of the most familiar financial transactions in both personal financial matters and engineering economic analysis involve nonannual payments; for example, monthly mortgage payments and daily earnings on savings accounts. Thus, if we are to compare different cash flows with different compounding periods, we need to address them on a common basis. The need to do this has led to the development of the concepts of *nominal interest rate* and *effective interest rate.*

Nominal Interest Rate

Even if a financial institution uses a unit of time other than a year — a month or quarter, for instance — in calculating interest payments, it usually quotes the interest rate on an annual basis. Many banks, for example, state the interest arrangement for credit cards in this way: "18% compounded monthly." We say 18% is the *nominal interest rate* or *annual percentage rate* (APR), and the compounding frequency is monthly (12). To obtain the interest rate per compounding period, we divide 18% by 12 to obtain 1.5% per month. Therefore, the credit card statement above means that the bank will charge 1.5% interest on unpaid balance for each month.

Although the annual percentage rate, or APR, is commonly used by financial institutions and is familiar to customers, when compounding takes place more frequently than annually, the APR does not explain precisely the amount of interest that will accumulate in a year. To explain the true effect of more frequent compounding on annual interest amounts, we need to introduce the term effective interest rate.

Effective Annual Interest Rate

The *effective interest rate* is the only one that truly represents the interest earned in a year or some other time period. For instance, in our credit card example, the bank will charge 1.5% interest on unpaid balance at the end of each month. Therefore, the 1.5% rate represents an effective interest rate — on a monthly basis, it is the rate that predicts the actual interest payment on your outstanding credit card balance.

Suppose you purchase an appliance on credit at 18% compounded monthly. Unless you pay off the entire amount within a grace period (let's say, a month), any unpaid balance (P) left for a year period would grow to

$$\begin{aligned} F &= P(1+i)^N \\ &= P(1+0.015)^{12} \\ &= 1.1956P \end{aligned}$$

This implies that for each dollar borrowed for 1 year, you owe \$1.1956 at the end of the year, including the principal and interest. For each dollar borrowed, you pay an equivalent annual interest of 19.56 cents. In terms of an effective annual interest rate (i_a), we can rewrite the interest payment as a percentage of the principal amount

$$i_a = (1+0.015)^{12} - 1 = 0.1956, \text{ or } 19.56\%$$

Thus, the effective annual interest rate is 19.56%.

Clearly, compounding more frequently increases the amount of interest paid for the year at the same nominal interest rate. We can generalize the result to compute the effective interest rate for *any time duration*. As you will see later, we normally compute the effective interest rate based on payment (transaction) period. For example, cash flow transactions occur quarterly but interest rate is compounded monthly. This quarterly conversion allows us to use the interest formulas in Table 17.2.1. To consider this, we may define the effective interest rate for a given payment period as

$$\begin{aligned} i &= (1 + r/M)^C - 1 \\ &= (1 + r/CK)^C - 1 \end{aligned} \tag{17.2.3}$$

where

M = the number of interest periods per year
C = the number of interest periods per payment period
K = the number of payment periods per year

When M = 1, we have the special case of annual compounding. Substituting M = 1 into Equation (17.2.3), we find it reduces to $i_a = r$. That is, when compounding takes place once annually,* effective interest is equal to nominal interest. Thus, in all our earlier examples, where we considered only annual interest, we were by definition using effective interest rates.

Example 17.2.5 — Calculating Auto Loan Payments

Suppose you want to buy a car priced $22,678.95. The car dealer is willing to offer a financing package with 8.5% annual percentage rate over 48 months. You can afford to make a down payment of $2678.95, so the net amount to be financed is $20,000. What would be the monthly payment?

Solution

The ad does not specify a compounding period, but in automobile financing the interest and the payment periods are almost always both monthly. Thus, the 8.5% APR means 8.5% compounded monthly. In this situation, we can easily compute the monthly payment using the *capital recovery factor* in Table 17.2.1:

$$i = 8.5\%/12 = 0.7083\% \text{ per month}$$

$$N = (12)(4) = 48 \text{ months}$$

$$A = \$20{,}000(A/P, 0.7083\%, 48) = \$492.97$$

Example 17.2.6 — Compounding More Frequent Than Payments

Suppose you make equal quarterly deposits of $1000 into a fund that pays interest at a rate of 12% compounded monthly. Find the balance at the end of year 2 (Figure 17.2.6).

Solution

We follow the procedure for noncomparable compounding and payment periods described above.

1. Identify the parameter values for M, K, and C:

$$M = 12 \text{ compounding periods per year}$$

$$K = 4 \text{ payment periods per year}$$

$$C = 3 \text{ interest periods per payment period}$$

---

* For an extreme case, we could consider a continuous compounding. As the number of compounding periods (M) becomes very large, the interest rate per compounding period (r/M) becomes very small. As M approaches infinity and r/M approaches zero, we approximate the situation of *continuous compounding*.

$$i = e^{r/K} - 1$$

To calculate the effective annual interest rate for continuous compounding, we set K equal to 1, resulting in:

$$i_a = e^r - 1$$

As an example, the effective annual interest rate for a nominal interest rate of 12% compounded continuously is $i_a = e^{0.12} - 1 = 12.7497\%$.

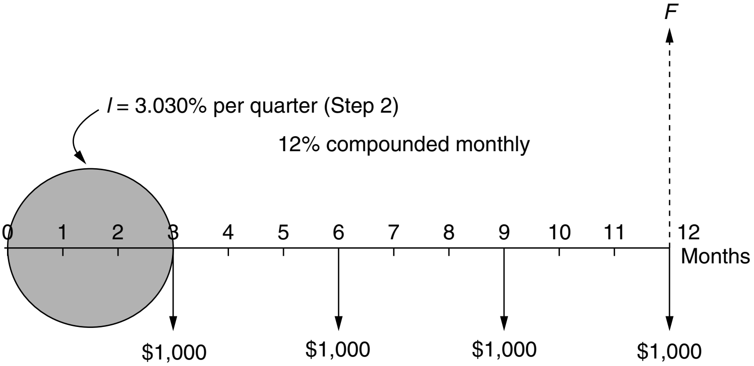

FIGURE 17.2.6 Quarterly deposits with monthly compounding (Example 17.2.6).

2. Use Equation (17.2.3) to compute effective interest per quarter.

$$\begin{aligned} i &= (1+0.12/12)^3 - 1 \\ &= 3.030\% \text{ per quarter} \end{aligned}$$

3. Find the total number of payment periods, N.

$$N = K(\text{number of years}) = 4(2) = 8 \text{ quarters}$$

4. Use i and N in the (F/A, i, N) factor from Table 17.2.1:

$$F = \$1000(F/A, 3.030\%, 8) = \$8901.81$$

Loss of Purchasing Power

It is important to differentiate between the time value of money as we used it in the previous section and the effects of inflation. The notion that a sum is worth more the earlier it is received can refer to its earning potential over time, to decreases in its value due to inflation over time, or to both. Historically, the general economy has usually fluctuated in such a way that it experiences *inflation*, a loss in the purchasing power of money over time. Inflation means that the cost of an item tends to increase over time or, to put it another way, the same dollar amount buys less of an item over time. *Deflation* is the opposite of inflation (negative inflation), in that prices decrease over time and hence a specified dollar amount gains in purchasing power. In economic equivalence calculations, we need to consider the change of purchasing power along with the earning power.

The Average Inflation Rate

To account for the effect of varying yearly inflation rates over a period of several years, we can compute a single rate that represents an *average inflation rate.* Since each individual year's inflation rate is based on the pervious year's rate, they have a compounding effect. As an example, suppose we want to calculate the average inflation rate for a 2-year period for a typical item. The first year's inflation rate is 4% and the second year's is 8%, using a base price index of 100.

- Step 1. We find the price at the end of the second year by the process of compounding:

$$\underbrace{\underbrace{100(1+0.04)}_{}(1+0.08)}_{} = 112.32$$

- Step 2. To find the average inflation rate f over a 2-year period, we establish the following equivalence equation:

$$100(1+f)^2 = 112.32 \leftarrow 100(F/P, f, 2) = 112.32$$

  Solving for f yields

$$f = 5.98\%$$

We can say that the price increases in the last 2 years are equivalent to an average annual percentage rate of 5.98% per year. In other words, our purchasing power decreases at the annual rate of 5.98% over the previous year's dollars. If the average inflation rate is calculated based on the *consumer price index* (CPI), it is known as a *general inflation rate* $(\bar{f})$.

Actual vs. Constant Dollars

To introduce the effect of inflation into our economic analysis, we need to define several inflation-related terms.*

- Actual (current) dollars (A_n): Estimates of future cash flows for year n which take into account any anticipated changes in amount due to inflationary or deflationary effects. Usually these amounts are determined by applying an inflation rate to base year dollar estimates.
- Constant (real) dollars (A'_n): Dollars of constant purchasing power independent of the passage of time. In situations where inflationary effects have been assumed when cash flows were estimated, those estimates can be converted to constant dollars (base year dollars) by adjustment using some readily accepted *general inflation rate*. We will assume that the base year is always time 0 unless we specify otherwise.

Equivalence Calculation under Inflation

In previous sections, our equivalence analyses have taken into consideration changes in the *earning power* of money — that is, interest effects. To factor in changes in *purchasing power* as well — that is, inflation — we may use either (1) constant dollar analysis or (2) actual dollar analysis. Either method will produce the same solution; however, each uses a different interest rate and procedure.

There are two types of interest rate for equivalence calculation: (1) the market interest rate and (2) the inflation-free interest rate. The interest rate that is applicable depends on the assumptions used in estimating the cash flow.

- Market interest rate (i): This interest rate takes into account the combined effects of the earning value of capital (earning power) and any anticipated inflation or deflation (purchasing power). Virtually all interest rates stated by financial institutions for loans and savings accounts are market interest rates. Most firms use a market interest rate (also known as *inflation-adjusted rate of return* [*discount rate*]) in evaluating their investment projects.
- Inflation-free interest rate (i′): An estimate of the true earning power of money when inflation effects have been removed. This rate is commonly known as *real interest rate* and can be computed if the market interest rate and inflation rate are known.

In calculating any cash flow equivalence, we need to identify the nature of project cash flows. There are three common cases:

Case 1. All cash flow elements are estimated in constant dollars. Then, to find the equivalent present value of a cash flow series in constant dollars, use the inflation-free interest rate.

---

* Based on the ANSI Z94 Standards Committee on Industrial Engineering Terminology. 1988. *The Engineering Economist.* Vol. 33(2): 145–171.

Case 2. All cash flow elements are estimated in actual dollars. Then, use the market interest rate to find the equivalent worth of the cash flow series in actual dollars.

Case 3. Some of the cash flow elements are estimated in constant dollars and others are estimated in actual dollars. In this situation, we simply convert all cash flow elements into one type — either constant or actual dollars. Then we proceed with either constant-dollar analysis for case 1 or actual-dollar analysis for case 2.

Removing the effect of inflation by deflating the actual dollars with $\bar{f}$ and finding the equivalent worth of these constant dollars by using the inflation-free interest rate can be greatly streamlined by the efficiency of the *adjusted-discount method*, which performs deflation and discounting in one step. Mathematically we can combine this two-step procedure into one by

$$i = i' + \bar{f} + i'\bar{f} \tag{17.2.4}$$

This implies that the market interest rate is a function of two terms, i', $\bar{f}$. Note that if there is no inflationary effect, the two interest rates are the same ($\bar{f} = 0 \rightarrow i = i'$). As either i' or $\bar{f}$ increases, i also increases. For example, we can easily observe that when prices are increasing due to inflation, bond rates climb, because lenders (that is anyone who invests in a money-market fund, bond, or certificate of deposit) demand higher rates to protect themselves against the eroding value of their dollars. If inflation were at 3%, you might be satisfied with an interest rate of 7% on a bond because your return would more than beat inflation. If inflation were running at 10%, however, you would not buy a 7% bond; you might insist instead on a return of at least 14%. On the other hand, when prices are coming down, or at least are stable, lenders do not fear the loss of purchasing power with the loans they make, so they are satisfied to lend at lower interest rates.

17.3 Measures of Project Worth

This section shows how to compare alternatives on equal basis and select the wisest alternative from an economic standpoint. The three common measures based on cash flow equivalence are (1) equivalent present worth, (2) equivalent annual worth, and (3) rate of return. The present worth represents a measure of future cash flow relative to the time point "now" with provisions that account for earning opportunities. Annual worth is a measure of the cash flow in terms of the equivalent equal payments on an annual basis. The third measure is based on *yield* or percentage.

Describing Project Cash Flows

When a company purchases a fixed asset such as equipment, it makes an investment. The company commits funds today in the expectation of earning a return on those funds in the future. Such an investment is similar to that made by a bank when it lends money. For the bank loan, the future cash flow consists of interest plus repayment of the principal. For the fixed asset, the future return is in the form of cash flows from the profitable use of the asset. In evaluating a capital investment, we are concerned only with those cash flows that result directly from the investment. These cash flows, called *differential* or *incremental cash flows*, represent the change in the firm's total cash flow that occurs as a direct result of the investment.

We must also recognize that one of the most important parts of the capital budgeting process is the estimation of the relevant cash flows. For all examples in this section, however, net cash flows can be viewed as before-tax values or after-tax values for which tax effects have been recalculated. Since some organizations (e.g., governments and nonprofit organizations) are not taxable, the before-tax situation can be a valid base for that type of economic evaluation. This view will allow us to focus on our main area of concern, the economic evaluation of an investment project. The procedures for determining after-tax net cash flows in taxable situations are developed in Section 17.4.

Example 17.3.1 — Identifying Project Cash Flows

Merco Inc., a machinery builder in Louisville, KY, is considering making an investment of $1,250,000 in a complete structural-beam-fabrication system. The increased productivity resulting from the installation of the drilling system is central to the justification. Merco estimates the following figures as a basis for calculating productivity:

- Increased fabricated steel production: 2000 tons/year
- Average sales price/ton fabricated steel: $2566.50/ton
- Labor rate: $10.50/hr
- Tons of steel produced in a year: 15,000 tons
- Cost of steel per ton (2205 lb): $1950/ton
- Number of workers on layout, holemaking, sawing, and material handling: 17
- Additional maintenance cost: $128,500 per year

With the cost of steel at $1950/ton and the direct labor cost of fabricating 1 lb at 10 cents, the cost of producing a ton of fabricated steel is about $2170.50. With a selling price of $2566.50/ton, the resulting contribution to overhead and profit becomes $396/ton. Assuming that Merco will be able to sustain an increased production of 2000 tons per year by purchasing the system, the projected additional contribution has been estimated to be 2000 tons × $396 = $792,000.

Since the drilling system has the capacity to fabricate the full range of structural steel, two workers can run the system, one on the saw and the other on the drill. A third operator is required as a crane operator for loading and unloading materials. Merco estimates that to do the equivalent work of these three workers with conventional manufacture requires, on the average, an additional 14 people for centerpunching, holemaking with radial or magnetic drill, and material handling. This translates into a labor savings in the amount of $294,000 per year ($10.50 × 40 hr/week × 50 weeks/year × 14). The system can last for 15 years with an estimated after-tax salvage value of $80,000. The expected annual corporate income taxes would amount to $226,000. Determine the net cash flow from undertaking the investment. Determine the net cash flows from the project over the service life.

Solution

The net investment cost as well as savings are as follows:

- Cash inflows:
  Increased annual revenue: $792,000
  Projected annual net savings in labor: $294,000
  Projected after-tax salvage value at the end of year 15: $80,000
- Cash outflows:
  Project investment cost: $1,250,000
  Projected increase in annual maintenance cost: $128,500
  Projected increase in corporate income taxes: $226,000

Now we are ready to summarize a cash flow table as follows:

Year	Cash Inflows	Cash Outflows	Net Cash Flows
0	0	$1,250,000	–$1,250,000
1	1,086,000	354,500	731,500
2	1,086,000	354,500	731,500
⋮	⋮	⋮	⋮
15	1,086,000 + 80,000	354,500	811,500

The project's cash flow diagram is shown in Figure 17.3.1.

Assuming these cost savings and cash flow estimates are correct, should management give the go-ahead for installation of the system? If management has decided not to install the fabrication system,

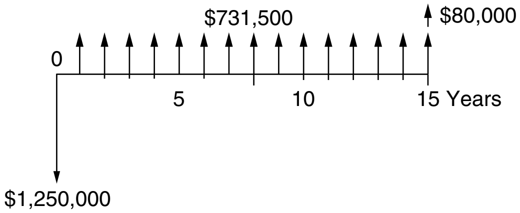

FIGURE 17.3.1 Cash flow diagram (Example 17.3.1).

what do they do with the $1,250,000 (assuming they have it in the first place)? The company could buy $1,250,000 of Treasury bonds. Or it could invest the amount in other cost-saving projects. How would the company compare cash flows that differ both in timing and amount for the alternatives it is considering? This is an extremely important question because virtually every engineering investment decision involves a comparison of alternatives. These are the types of questions this section is designed to help you answer.

Present Worth Analysis

Until the 1950s, the payback method* was widely used as a means of making investment decisions. As flows in this method were recognized, however, business people began to search for methods to improve project evaluations. This led to the development of discounted cash flow techniques (DCF), which take into account the time value of money. One of the DCFs is the net present worth method (NPW). A capital investment problem is essentially one of determining whether the anticipated cash inflows from a proposed project are sufficiently attractive to invest funds in the project. In developing the NPW criterion, we will use the concept of cash flow equivalence discussed in Section 17.2. Usually, the most convenient point at which to calculate the equivalent values is often time 0. Under the NPW criterion, the present worth of all cash inflows is compared against the present worth of all cash outflows that are associated with an investment project. The difference between the present worth of these cash flows, called the *net present worth* (NPW), determines whether or not the project is an acceptable investment. When two or more projects are under consideration. NPW analysis further allows us to select the best project by comparing their NPW figures.

We will first summarize the basic procedure for applying the present worth criterion to a typical investment project.

- Determine the interest rate that the firm wishes to earn on its investments. This represents an interest rate at which the firm can always invest the money in its *investment pool*. We often refer to this interest rate as either a *required rate of return* or a *minimum attractive rate of return* (MARR). Usually this selection will be a policy decision by top management. It is possible for the MARR to change over the life of a project, but for now we will use a single rate of interest in calculating NPW.

---

* One of the primary concerns of most business people is whether and when the money invested in a project can be recovered. The *payback method* screens projects on the basis of how long it takes for net receipts to equal investment outlays. A common standard used in determining whether or not to pursue a project is that no project may be considered unless its payback period is shorter than some specified period of time. If the payback period is within the acceptable range, a formal project evaluation (such as the present worth analysis) may begin. It is important to remember that payback screening is not an *end* itself, but rather a method of screening out certain obvious unacceptable investment alternatives before progressing to an analysis of potentially acceptable ones. But the much-used payback method of equipment screening has a number of serious drawbacks. The principal objection to the payback method is its failure to measure profitability; that is, there is no "profit" made during the payback period. Simply measuring how long it will take to recover the initial investment outlay contributes little to gauging the earning power of a project.

- Estimate the service life of the project.*
- Determine the net cash flows (net cash flow = cash inflow – cash outflow).
- Find the present worth of each net cash flow at the MARR. Add up these present worth figures; their sum is defined as the project's NPW.
- Here, a positive NPW means the equivalent worth of inflows are greater than the equivalent worth of outflows, so project makes a profit. Therefore, if the PW(i) is positive for a single project, the project should be accepted; if negative, it should be rejected. The decision rule is

$$\text{If } PW(i) > 0, \text{ accept the investment}$$

$$\text{If } PW(i) = 0, \text{ remain indifferent}$$

$$\text{If } PW(i) < 0, \text{ reject the investment}$$

Note that the decision rule is for a single project evaluation where you can estimate the revenues as well as costs associated with the project. As you will find later, when you are comparing alternatives with the same revenues, you can compare them based on the cost only. In this situation (because you are minimizing costs, rather than maximizing profits), you should accept the project that results in smallest, or least negative, NPW.

Example 17.3.2 — Net Present Worth

Consider the investment cash flows associated with the metal fabrication project in Example 17.3.1. If the firm's MARR is 15%, compute the NPW of this project. Is this project acceptable?

Solution

Since the fabrication project requires an initial investment of \$1,250,000 at n = 0 followed by the 15 equal annual savings of \$731,500, and \$80,000 salvage value at the end of 15 years, we can easily determine the NPW as follows:

$$PW(15\%)_{outflow} = \$1,250,000$$

$$\begin{aligned} PW(15\%)_{inflow} &= \$731,500(P/A,15\%,15) + \$80,000(P/F,15\%,15) \\ &= \$4,284,259 \end{aligned}$$

---

* Another special case of the PW criterion is useful when the life of a proposed project is *perpetual* or the planning horizon is extremely long. The process of computing the PW cost for this infinite series is referred to as the *capitalization* of project cost. The cost is known as the *capitalized cost.* It represents the amount of money that must be invested today to yield a certain return A at the end of each and every period forever, assuming an interest rate of i. Observe the limit of the uniform series present worth factor as N approaches infinity:

$$\lim_{N\to\infty}(P/A,i,N) = \lim_{N\to\infty}\left[\frac{(1+i)^N - 1}{i(1+i)^N}\right] = \frac{1}{i}$$

Thus, it follows that

$$PW(i) = A(P/A,i,N \to \infty) = \frac{A}{i} \tag{17.5}$$

Another way of looking at this, PW(i) dollars today, is to ask what constant income stream could be generated by this in perpetuity. Clearly, the answer is A = iPW(i). If withdrawals were greater than A, they could be eating into the principal, which would eventually reduce to 0.

Then, the NPW of the project is

$$\begin{aligned} PW(15\%) &= PW(15\%)_{in\ flow} - PW(15\%)_{out\ flow} \\ &= \$4,284,259 - \$1,250,000 \\ &= \$3,034,259 \end{aligned}$$

Since PW (15%) > 0, the project would be acceptable.

Annual Equivalent Method

The annual equivalent worth (AE) criterion is a basis for measuring investment worth by determining equal payments on an annual basis. Knowing that we can convert any lump-sum cash amount into a series of equal annual payments, we may first find the NPW for the original series and then multiply the NPW by the capital recovery factor:

$$AE(i) = PW(i)(A/P,i,N) \tag{17.3.1}$$

The accept-reject decision rule for a single *revenue* project is

$$\begin{aligned} &\text{If } AE(i) > 0, \text{ accept the investment} \\ &\text{If } AE(i) = 0, \text{ remain indifferent} \\ &\text{If } AE(i) < 0, \text{ reject the investment} \end{aligned}$$

Notice that the factor (A/P, i, N) in Table 17.2.1 is positive for $-1 < i < \infty$. This indicates that the AE(i) value will be positive if and only if PW(i) is positive. In other words, accepting a project that has a positive AE(i) value is equivalent to accepting a project that has a positive PW(i) value. Therefore, the AE criterion should provide a basis for evaluating a project that is consistent with the NPW criterion.

As with the present worth analysis, when you are comparing mutually exclusive *service* projects whose revenues are the same, you may compare them based on *cost* only. In this situation, you will select the alternative with the minimum annual equivalent cost (or least negative annual equivalent worth).

Unit Profit/Cost Calculation

There are many situations in which we want to know the unit profit (or cost) of operating an asset. A general procedure to obtain such a unit profit or cost figure involves the following two steps:

- Determine the number of units to be produced (or serviced) each year over the life of the asset.
- Identify the cash flow series associated with the production or service over the life of the asset.
- Calculate the net present worth of the project cash flow series at a given interest rate and then determine the equivalent annual worth.
- Divide the equivalent annual worth by the number of units to be produced or serviced during each year. When you have the number of units varying each year, you may need to convert them into equivalent annual units.

To illustrate the procedure, we will consider Example 17.3.3, where the annual equivalent concept can be useful in estimating the savings per machine hour for a proposed machine acquisition.

Example 17.3.3 — Unit Profit per Machine Hour

Tiger Machine Tool Company is considering the proposed acquisition of a new metal-cutting machine. The required initial investment of $75,000 and the projected cash benefits and annual operating hours over the 3-year project life are as follows.
Compute the equivalent savings per machine hour at i = 15%.

End of Year	Net Cash Flow	Operating Hours
0	–$75,000	
1	24,400	2,000
2	27,340	2,000
3	55,760	2,000

Solution
Bringing each flow to its equivalent at time zero, we find

$$\begin{aligned} PW(15\%) &= -\$75{,}000 + \$24{,}400(P/F,15\%,1) + \$27{,}340(P/F,15\%,2) + \$55{,}760(P/F,15\%,3) \\ &= \$3553 \end{aligned}$$

Since the project results in a surplus of $3553, the project would be acceptable. We first compute the annual equivalent savings from the use of the machine. Since we already know the NPW of the project, we obtain the AE by

$$AE(15\%) = \$3553(A/P,15\%,3) = \$1556$$

With an annual usage of 2000 hr, the equivalent savings per machine hour would be

$$\text{Savings per machine hour} = \$1556/\$2000\text{ hr} = \$0.78/\text{hr}$$

Comments
Note that we cannot simply divide the NPW amount ($3553) by the total number of machine hours over the 3-year period (6000 hr), or $0.59/hr. This $0.59 figure represents the *instant savings* in present worth for each hourly use of the equipment, but does not consider the time over which the savings occur. Once we have the annual equivalent worth, we can divide by the desired time unit if the compounding period is 1 year. If the compounding period is shorter, then the equivalent worth should be calculated for the compounding period.

Rate of Return Analysis

Along with the NPW and AE, the third primary measure of investment worth is based on yield, known as *rate of return*. The NPW measure is easy to calculate and apply. Nevertheless, many engineers and financial managers prefer rate of return analysis to the NPW method because they find it intuitively more appealing to analyze investments in terms of percentage rates of return than in dollars of NPW.

Internal Rate of Return

Many different terms refer to rate of return, including yield (that is, the yield to maturity, commonly used in bond valuation), internal rate of return, and marginal efficiency of capital. In this section, we will define *internal rate of return* as the break-even interest rate, i^*, which equates the present worth of a project's cash outflows to the present worth of its cash inflows, or

$$\begin{aligned} PW(i^*) &= PW_{\text{cash inflows}} - PW_{\text{cash outflows}} \\ &= 0 \end{aligned}$$

Note that the NPW expression is equivalent to

$$PW(i^*) = \frac{A_0}{(1+i^*)^0} + \frac{A_1}{(1+i^*)^1} + \cdots + \frac{A_N}{(1+i^*)^N} = 0 \qquad (17.3.2)$$

Here we know the value of A_n for all n, but not the value of i^*. Since it is the only unknown, we can solve for i^*. There will inevitably be N values of i^* that satisfy this equation. In most project cash flows you would be able to find a unique positive i^* that satisfies Equation (17.3.2). However, you may encounter some cash flow that cannot be solved for a single rate of return greater than –100%. By the nature of the NPW function in Equation (17.3.2), it is certainly possible to have more than one rate of return for a certain type of cash flow.* (For some cash flows, we may not find any rate of return at all.)

Finding the IRR

We don't need laborious manual calculations to find i^*. Many financial calculators have built-in functions for calculating i^*. It is also worth noting here that many spreadsheet packages have i^* functions, which solve Equation (17.3.2) very rapidly. This is normally done by entering the cash flows through a computer keyboard or by reading a cash flow data file. As an alternative, you could try the trial-and-error method to locate the break-even interest that makes the net present worth equal to zero.

Accept/Reject Decision Rules

Why are we interested in finding the particular interest rate that equates a project's cost with the present worth of its receipts? Again, we may easily answer this by examining Figure 17.3.2. In this figure, we notice two important characteristics of the NPW profile. First, as we compute the project's PW(i) at a varying interest rate (i), we see that the NPW becomes positive for $i < i^*$, indicating that the project would be acceptable under the PW analysis for those values of i. Second, the NPW becomes negative for $i > i^*$, indicating that the project is unacceptable for those values of i. Therefore, the i^* serves as a *break-even* interest rate. By knowing this break-even rate, we will be able to make an accept/reject decision that is consistent with the NPW analysis.

At the MARR the company will more than break even. Thus, the IRR becomes a useful gauge against which to judge project acceptability, and the decision rule for a simple project is

$$\begin{aligned} &\text{If IRR} > \text{MARR}, \text{ accept the project} \\ &\text{If IRR} = \text{MARR}, \text{ remain indifferent} \\ &\text{If IRR} < \text{MARR}, \text{ reject the project} \end{aligned}$$

Note that this decision rule is designed to be applied for a single project evaluation. When we have to compare mutually exclusive investment projects, we need to apply the incremental analysis, as we shall see in a later section.

Example 17.3.4 — Rate of Return Analysis

Reconsider the fabrication investment project in Example 17.3.1. (a) What is the projected IRR on this fabrication investment? (b) If Merco's MARR is known to be 15%, is this investment justifiable?

---

* When applied to projects that require investments at the outset followed by a series of cash inflows (or a simple project), the i^* provides an unambiguous criterion for measuring profitability. However, when multiple rates of return occur, none of them is an accurate portrayal of project acceptability or profitability. Clearly, then, we should place a high priority on discovering this situation early in our analysis of a project's cash flows. The quickest way to predict multiple i^*s is to generate a NPW profile and check to see if it crosses the horizontal axis more than once.

In addition to the NPW profile, there are good — although somewhat more complex — analytical methods for predicting multiple i^*s. Perhaps more importantly, there is a good method, which uses a *cost of capital*, of refining our analysis when we do discover multiple i^*s. Use of a cost of capital allows us to calculate a single accurate rate of return (also known as *return on invested capital*); it is covered in *Contemporary Engineering Economics*, C.S. Park, Addison-Wesley, 1997. If you choose to avoid these more complex applications of rate-of-return techniques, you must at a minimum be able to predict multiple i^*s via the NPW profile and, when they occur, select an alternative method such as NPW or AE analysis for determining project acceptability.

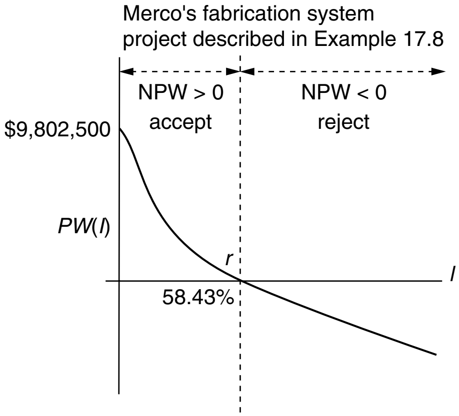

FIGURE 17.3.2 A net present worth profile for the cash flow series given in Figure 17.3.1 at varying interest rates. The project breaks even at 58.43% so that the NPW will be positive as long as the discount rate is less than 58.43%.

Solution

- (a) The net present worth expression as a function of interest rate (i) is

$$\begin{aligned} PW(i) &= -\$1{,}250{,}000 + \$731{,}500(P/A,i,15) + \$80{,}000(P/F,i,15) \\ &= 0 \end{aligned}$$

  Using Excel's financial function (IRR), we find the IRR to be 58.43%. (See Figure 17.3.2.) Merco will recover the initial investment fully and also earn 58.43% interest on its invested capital.
- (b) If Merco does not undertake the project, the $1,250,000 would remain in the firm's investment pool and continue to earn only 15% interest. The IRR figure far exceeds the Merco's MARR, indicating that the fabrication system project is an economically attractive one. Merco's management believes that, over a broad base of structural products, there is no doubt that the installation of its fabricating system would result in a significant savings, even after considering some potential deviations from the estimates used in the analysis.

Mutually Exclusive Alternatives

Until now, we have considered situations in which only one project was under consideration, and we were determining whether to pursue it, based on whether its present worth or rate of return met our MARR requirements. We were making an accept or reject decision about a *single* project.

In the real world of engineering practice, however, it is more typical for us to have two or more choices of projects for accomplishing a business objective. *Mutually exclusive* means that any one of several alternatives will fulfill the same need and that selecting one alternative means that the others will be excluded.

Analysis Period

The *analysis period* is the time span over which the economic effects of an investment will be evaluated. The analysis period may also be called the *study period* or *planning horizon*. The length of the analysis period may be determined in several ways: it may be a predetermined amount of time set by company policy, or it may be either implied or explicit in the need the company is trying to fulfill. In either of these situations, we consider the analysis period to be a *required service period*. When no required service period is stated at the outset, the analyst must choose an appropriate analysis period over which to study the alternative investment projects. In such a case, one convenient choice of analysis period is the period of useful life of the investment project.

When useful life of the investment project does not match the analysis or required service period, we must make adjustments in our analysis. A further complication, when we are considering two or more mutually exclusive projects, is that the investments themselves may have differing useful lives. We must compare projects with different useful lives over an *equal time span*, which may require further adjustments in our analysis.

Analysis Period Equals Project Lives

Let's begin our analysis with the simplest situation where the project lives equal the analysis period. In this case, we compute the NPW for each project and select the one with highest NPW for revenue projects or least negative NPW for service projects. Example 17.3.5 will illustrate this point.

Example 17.3.5 — Two Mutually Exclusive Alternatives

A pilot wants to start her own company to airlift goods to the Commonwealth of Independent States (formerly the U.S.S.R.) during their transition to a free-market economy. To economize the start-up business, she decides to purchase only one plane and fly it herself. She has two mutually exclusive options: an old aircraft (A1) or a new jet (A2) with which she expects to have higher purchase costs, but higher revenues as well because of its larger payload. In either case, she expects to fold up business in 3 years because of competition from larger companies. The cash flows for the two mutually exclusive alternatives are given in thousand dollars:

n	A1	A2
0	–3,000	–$12,000
1	1,350	4,200
2	1,800	6,225
3	1,500	6,330

Assuming that there is no do-nothing alternative, which project would she select at MARR = 10%?

Solution

Since the required service period is 3 years, we should select the analysis period of 3 years. Since the analysis period coincides with the project lives, we simply compute the NPW value for each option. The equivalent NPW figures at $i = 10\%$ would be as follows:

- For A1:

$$
\begin{aligned}
PW(15\%)_{A1} &= -\$3000 + \$1350(P/F,10\%,1) + \$1800(P/F,10\%,2) + \$1500(P/F,10\%,3) \\
&= \$842
\end{aligned}
$$

- For A2:

$$
\begin{aligned}
PW(15\%)_{A2} &= -\$12{,}000 + \$4200(P/F,10\%,1) + \$6225(P/F,10\%,2) + \$6330(P/F,10\%,3) \\
&= \$1719
\end{aligned}
$$

Clearly, A2 is the most economical option.

Project Lives Differ from a Specified Analysis Period

Often project lives do not match the required analysis period and/or do not match each other. For example, two machines may perform exactly the same function, but one lasts longer than the other and both of them last longer than the analysis period for which they are being considered. We are then left with some unused portion of the equipment, which we include as salvage value in our analysis. Salvage value is the amount of money for which the equipment could be sold after its service or the dollar measure of its remaining usefulness.

When project lives are shorter than the required service period, we must consider how, at the end of the project lives, we will satisfy the rest of the required service period. Replacement projects — additional projects to be implemented when the initial project has reached the limits of its useful life — are needed in such a case. Sufficient replacement projects must be analyzed to match or exceed the required service period.

To simplify our analysis, we sometimes assume that the replacement project will be exactly the same as the initial project, with the same corresponding costs and benefits. However, this assumption is not necessary. For example, depending on our forecasting skills, we may decide that a different kind of technology — in the form of equipment, materials, or processes — is a preferable replacement. Whether we select exactly the same alternative or a new technology as the replacement project, we are ultimately likely to have some unused portion of the equipment to consider as salvage value at the end of the required service period. On the other hand, if a required service period is relatively short, we may decide to lease the necessary equipment or subcontract the remaining work for the duration of the analysis period. In this case, we can probably exactly match our analysis period and not worry about salvage values.

Example 17.3.6 — Present Worth Comparison — Project Lives Shorter Than Analysis Period

The Smith Novelty Company, a mail-order firm, wants to install an automatic mailing system to handle product announcements and invoices. The firm has a choice between two different types of machines. The two machines are designed differently but have identical capacities and do exactly the same job. The $12,500 semiautomatic model A will last 3 years with a salvage value of $2000, while the fully automatic model B will cost $15,000 and last 4 years with a salvage value of $1500. The expected cash flows for the two machines including maintenance, salvage value, and tax effects are as follows:

n	Model A	Model B
0	–12,500	–$15,000
1	–5,000	–4,000
2	–5,000	–4,000
3	–5,000 + 2,000	–4,000
4		–4,000 + 1,500
5		

As business grows to a certain level, neither of the models can handle the expanded volume at the end of year 5. If that happens, a fully computerized mail-order system will need to be installed to handle the increased business volume. With this scenario, which model should the firm select at MARR = 15%?

Solution

Since both models have a shorter life than the required service period (5 years), we need to make an explicit assumption of how the service requirement is to be met. Suppose that the company considers leasing comparable equipment that has an annual lease payment of $6000 (after taxes) for the remaining required service period. In this case, the cash flow would look like Figure 17.3.3.

n	*Model A*	*Model B*
0	–12,500	–$15,000
1	–5,000	–4,000
2	–5,000	–4,000
3	–3,000	–4,000
4	**–6,000** –5,000	–2,500
5	**–6,000** –5,000	**–6,000** –5,000

Here the bold figures represent the annual lease payments. (It costs $6000 to lease the equipment and $5000 to operate anually. Other maintenance will be paid by the leasing company.) Note that both alternatives now have the same required service period of 5 years. Therefore, we can use NPW analysis.

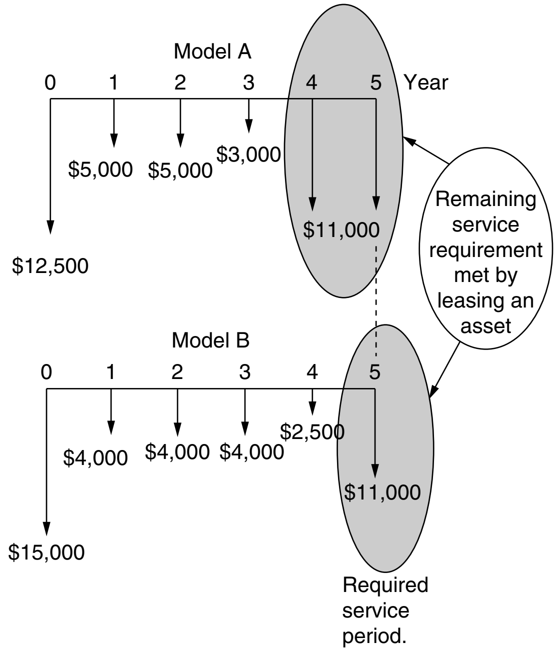

FIGURE 17.3.3 Comparison for unequal-lived projects when the required service period is longer then the individual project life (Example 17.3.6.)

$$
\begin{aligned}
PW(15\%)_A &= -\$12{,}500 - \$5000(P/A,15\%,2) + \$3000(P/F,15\%,3) \\
&\quad - \$11{,}000(P/A,15\%,2)(P/F,15\%,3) \\
&= -\$34{,}359
\end{aligned}
$$

$$
\begin{aligned}
PW(15\%)_B &= -\$15{,}000 - \$4000(P/A,15\%,3) - \$2500(P/F,15\%,4) - \$11{,}000(P/F,15\%,5) \\
&= -\$32{,}747
\end{aligned}
$$

Since these are service projects, model B is the better choice.

Flaws in Project Ranking by IRR

Under NPW, the mutually exclusive project with the highest worth figure was preferred. Unfortunately, the analogy does not carry over to IRR analysis. The project with the highest IRR may *not* be the preferred alternative. To illustrate the flaws of comparing IRRs to choose from mutually exclusive projects, suppose you have two mutually exclusive alternatives, each with a 1-year service life; one requires an investment of $1000 with a return of $2000 and the other requires $5000 with a return of $7000. You already obtained the IRRs and NPWs at MARR = 10% as follows:

n	A1	A2
0	–$1000	–$5000
1	222000	7000
IRR	100%	40%
PW(10%)	$818	$1364

Would you prefer the first project simply because you expect a higher rate of return?

We can see that A2 is preferred over A1 by the NPW measure. On the other hand, the IRR measure gives a *numerically* higher rating for A1. This inconsistency in ranking is due to the fact that the NPW is an *absolute (dollar)* measure of investment worth, while the IRR is a *relative (percentage)* measure and cannot be applied in the same way. That is, the IRR measure ignores the *scale* of the investment. Therefore, the answer is no; instead, you would prefer the second project with the lower rate of return, but higher NPW. The NPW measure would lead to that choice, but comparison of IRRs would rank the smaller project higher. Another approach, called *incremental analysis*, is needed.

Rate of Return on Incremental Investment

In our previous ranking example, the more costly option requires an incremental investment of $4000 at an incremental return of $5000. If you decide to take the more costly option, certainly you would be interested in knowing that this additional investment can be justified at the MARR. The 10% of MARR value implies that you can always earn that rate from other investment sources — $4400 at the end of 1 year for $4000 investment. However, by investing the additional $4000 in the second option, you would make an additional $5000, which is equivalent to earning at the rate of 25%. Therefore, the incremental investment can be justified.

Now we can generalize the decision rule for comparing mutually exclusive projects. For a pair of mutually exclusive projects (A, B), rate of return analysis is done by computing the *internal rate of return on incremental investment* (IRR_Δ) between the projects. Since we want to consider increments of investment, we compute the cash flow for the difference between the projects by subtracting the cash flow for the lower investment-cost project (A) from that of the higher investment-cost project (B). Then, the decision rule is select B, if $\text{IRR}_{\text{B-A}} > \text{MARR}$. Otherwise select A.

Example 17.3.7 — IRR on Incremental Investment: Two Alternatives

Reconsider the two mutually exclusive projects in Example 17.3.5.

n	B1	B2	B2–B1
0	–$3,000	–$12,000	–$9,000
1	1,350	4,200	2,850
2	1,800	6,225	4,425
3	1,500	6,330	4,830
IRR	25%	17.43%	

Since B1 is the lower cost investment project, we compute the incremental cash flow for B2–B1. Then we compute the IRR on this increment of investment by solving

$$-\$9000 + \$2850(P/F,i,1) + \$4425(P/F,i,2) + \$4830(P/F,i,3) = 0$$

We obtain $i^*_{\text{B2-B1}} = 15\%$. Since $\text{IRR}_{\text{B2-B1}} > \text{MARR}$, we select B2, which is consistent with the NPW analysis.

Comments

Why did we choose to look at the increment B2-B1 instead of B1-B2? We want the increment to have investment during at least some part of the time span so that we can calculate an IRR. Subtracting the lower initial investment project from the higher guarantees that the first increment will be investment flow. Ignoring the investment ranking, we might end up with an increment which involves borrowing cash flow and has no internal rate of return. This is the case for B1-B2. ($i^*_{\text{B1-B2}}$ is also 15%, not –15%.) If we erroneously compare this i^* with MARR, we might have accepted project B1 over B2.

17.4 Cash Flow Projections

With the purchase of any fixed asset such as equipment, we need to estimate the profits (more precisely, cash flows) that the asset will generate during its service period. An inaccurate estimate of asset needs can have serious consequences. If you invest too much in assets, you incur unnecessarily heavy expenses. Spending too little on fixed assets also is harmful, for then the firm's equipment may be too obsolete to produce products competitively and without an adequate capacity you may lose a portion of your market share to rival firms. Regaining lost customers involves heavy marketing expenses and may even require price reductions and/or product improvements, all of which are costly. We will begin this section by giving an overview on how a company determines its operating profit.

Operating Profit — Net Income

Firms invest in a project because they expect it to increase their wealth. If the project does this — if project revenues exceed project costs — we say it has generated a *profit*, or *income*. If the project reduces the owner's wealth, we say that the project has resulted in a *loss*. One of the most important roles of the accounting function within an organization is to measure the amount of profit or loss a project generates each year or in any other relevant time period. Any profit generated will be taxed. The accounting measure of a project's after-tax profit during a particular time period is known as *net income.*

Accountants measure the net income of a specified operating period by subtracting expenses from revenues for that period. These terms can be defined as follows:

1. The *project revenue* is the income earned by a business as a result of providing products or services to outsiders. Revenue comes from sales of merchandise to customers and from fees earned by services performed for clients or others.
2. The *project expenses* incurred are the cost of doing business to generate the revenues of that period. Some common expenses are the cost of the goods sold (labor, material, inventory, and supplies), depreciation, the cost of employees' salaries, the operating cost (such as the cost of renting a building and the cost of insurance coverage), and income taxes.

The business expenses listed above are all accounted for in a straightforward fashion on the income statement and balance sheet: the amount paid by the organization for each item would translate dollar for dollar into expenses in financial reports for the period. One additional category of expenses, the purchase of new assets, is treated by depreciating the total cost gradually over time. Because it plays a role in reducing taxable income, depreciation accounting is of special concern to a company.

Accounting Depreciation

The acquisition of fixed assets is an important activity for a business organization, whether the organization is starting up or acquiring new assets to remain competitive. The systematic allocation of the initial cost of an asset in parts over a time known as its depreciable life is what we mean by *accounting depreciation.* Because accounting depreciation is the standard of the business world, we sometimes refer to it more generally as *asset depreciation.*

The process of depreciating an asset requires that we make several preliminary determinations:

1. *What can be depreciable?* Depreciable property includes buildings, machinery, equipment, and vehicles. Inventories are not depreciable property because they are held primarily for sale to customers in the ordinary course of business. If an asset has no definite service life, the asset cannot be depreciated. For example, *you can never depreciate land.*
2. *What cost base should be used in asset depreciation?* The *cost base* of an asset represents the total cost that is claimed as an expense over an asset's life, that is, the sum of the annual depreciation expenses. The cost base generally includes the actual cost of the asset and all the other incidental expenses, such as freight, site preparation, and installation. This total cost, rather than the cost of the asset only, must be the depreciation base charged as an expense over the asset's life.
3. *What is the asset's value at the end of its useful life?* The salvage value is an asset's value at the end of its life; it is the amount eventually recovered through sale, trade-in, or salvage. The eventual salvage value of an asset must be estimated when the depreciation schedule for the asset is

established. If this estimate subsequently proves to be inaccurate, then an adjustment must be made.

4. *What is the depreciable life of the asset?* Historically, depreciation accounting included choosing a depreciable life that was based on the service life of an asset. Determining the service life of an asset, however, was often very difficult, and the uncertainty of these estimates often led to disputes between taxpayers and the IRS. To alleviate the problems, the IRS published guidelines on lives for categories of assets known as *Asset Depreciation Ranges*, or ADRs. These guidelines specified a range of lives for classes of assets based on historical data, and taxpayers were free to choose a depreciable life within the specified range for a given asset.
5. *What method of depreciation do we choose?* Companies generally calculate depreciation one way when figuring taxes and another way when reporting income (profit) to investors: (1) they use the straight-line method (or declining balance or sum-of-years' digits) for investors and (2) they use the fastest rate permitted by law (known as "modified accelerated cost recovery system [MACRS]") for tax purposes. Under the straight-line method, for an asset with a 5-year life which costs \$10,000 and has a \$1000 salvage value, the annual depreciation charge is (\$10,000 – \$1000)/5 = \$1800. For tax purposes, Congress created several classes of assets, each with a more or less arbitrarily prescribed life called a *recovery period* or *class life*. The depreciable base is not adjusted for salvage value, which is the estimated market value of the asset at the end of its useful life. Table 17.4.1 describes what types of property fit into the different class life groups and the allowed depreciation percentages. Congress developed these recovery allowance percentages based on the declining balance method, with a switch to straight-line depreciation at some point in the asset's life. The MACRS recovery percentages as shown in Table 17.4.1 also employ the half-year convention — that is, they assume that all assets are put into service at midyear and, hence, generate a half-year's depreciation.

Corporate Income Taxes

Corporate taxable income is defined as follows:

$$\begin{aligned}\text{taxable income} &= \text{gross income (revenues)}\\ &\qquad -(\text{cost of goods sold } + \text{ depreciation } + \text{ operating expenses})\end{aligned}$$

Once taxable income is calculated, income taxes are determined by

$$\text{income taxes} = (\text{tax rate}) \times (\text{taxable income})$$

The corporate tax rate structure for 1996 is relatively simple. There are four basic rate brackets (ranging from 15 to 35%) plus two surtax rates (5 and 3%) based on taxable incomes, and businesses with lower taxable incomes continue to be taxed at lower rates than those with higher taxable incomes.

Tax Treatment of Gains or Losses for Depreciable Assets

When a depreciable asset used in business is sold for an amount different from its book value, this gain or loss has an important effect on income taxes. An asset's book value at any given time is determined by

$$\text{book value} = \text{cost base} - \text{total amount of depreciation}$$

The gain or loss is found by

$$\text{gains (losses)} = \text{salvage value} - \text{book value}$$

TABLE 17.4.1 MACRS Depreciation Schedules for Personal Properties with Half-Year Convention

		Personal Property					
	Class	3	5	7	10	15	20
	Depreciation	200%	200%	200%	200%	150%	150%
Year	Rate	DB	DB	DB	DB	DB	DB
1		33.33	20.00	14.29	10.00	5.00	3.750
2		44.45	32.00	24.49	18.00	9.50	7.219
3		14.81*	19.20	17.49	14.40	8.55	6.677
4		7.41	11.52*	12.49	11.52	7.70	6.177
5			11.52	8.93*	9.22	6.93	5.713
6			5.76	8.92	7.37	6.23	5.285
7				8.93	6.55*	5.90*	4.888
8				4.46	6.55	5.90	4.522
9					6.56	5.91	4.462*
10					6.55	5.90	4.461
11					3.28	5.91	4.462
12						5.90	4.461
13						5.91	4.462
14						5.90	4.461
15						5.91	4.462
16						2.95	4.461
17							4.462
18							4.461
19							4.462
20							4.461
21							2.231

Note: "*" denotes year to switch from declining balance to straight line.

Property Class	Applicable Property
3-year	Machine tools
5-year	Automobiles, light trucks, high-tech equipment
7-year	Manufacturing equipment, office furniture
10-year	Vessels, barges, tugs, railroad cars
15-year	Utility property (water, telephone)
20-year	Municipal sewers, electrical power plant

where the salvage value represents the proceeds from the sale less any selling expense or removal cost.

These gains, commonly known as *depreciation recapture*, are taxed as ordinary income. In the unlikely event that if an asset is sold for an amount greater than its initial cost, the gains (salvage value – book value) are divided into two parts (ordinary gains and capital gains) for tax purposes:

$$\begin{aligned} \text{gains} &= \text{salvage value} - \text{book value} \\ &= \underbrace{(\text{salvage value} - \text{cost base})}_{\text{capital gains}} + \underbrace{(\text{cost base} - \text{book value})}_{\text{ordinary gains}} \end{aligned}$$

Capital gains are normally taxed at a different rate from that of ordinary gains.

After-Tax Cash Flow Analysis

In developing an after-tax flow, we are concerned only with those cash flows that result directly from the project. These cash flows, called *incremental cash flows*, represent the change in the firm's total cash flows that occurs as a direct result of undertaking the project. There are several elements that contribute toward the project cash flows. In preparing the cash flow statement which shows sources and uses of cash in project undertaking, we may group them into three areas: (1) cash flow elements associated with operations, (2) cash flow elements associated with investment activities (capital expenditures), and (3) cash flow elements associated with project financing (such as borrowing). The main purpose of this grouping is to provide information about the operating, investing, and financing activities of a project.

- *Operating Activities:* In general, cash flows from operations include current sales revenue, cost of goods sold, operating expense, and income taxes. Cash flows from operations should generally reflect the cash effects of transactions entering into the determination of net income. The interest portion of a loan repayment is a deductible expense when determining net income, and it is included in the operating activities. Since we will usually look only at yearly flows, it is logical to express all cash flows on a yearly basis. We can determine the net cash flow from operations either (1) based on net income or (2) based on cash flow by computing income taxes directly. When we use net income as the starting point for cash flow determination, we should add any noncash expenses (mainly depreciation) back to net income to compute the net cash flow. Thus,

$$\text{net operating cash flow} = \text{net income} + \text{noncash expenses}$$
$$\left(\text{depreciation}\right)$$

Approach 1	Approach 2
Cash revenues (savings)	Cash revenues (savings)
–Cost of goods sold	–Cost of goods sold
–Depreciation	
–Operating expense	–Operating expense
–Interest expense	–Interest expense
Taxable income	
–Income taxes	–Income taxes
Net income + depreciation	Operating cash flow

  In business practice, accountants usually prepare the cash flow statements based on the net income, namely, using Approach 1, whereas Approach 2 is commonly used in many traditional engineering economic texts. If you learn only Approach 2, it is more than likely that you need to be retrained to learn Approach 1 to communicate with the financing and accounting professionals within your organization. Therefore, we will use the income statement approach (Approach 1) whenever possible throughout this section.

- *Investing Activities:* Three types of investment flows are associated with buying a piece of equipment: the original investment, salvage value at the end of its useful life, and working capital investment* or recovery.** We will assume that our outflow for both capital investment and working capital investment is as if they take place in year 0. It is quite possible that both investments will not occur instantaneously, but rather over a few months as the project gets into gear; we could then use year 1 as an investment year. (Capital expenditures may occur over several years before a large investment project becomes fully operational. In this case, we should enter all expenditures

---

* Normally, additional inventories are required to support a new operation and increased accounts receivable. These increases in current assets must be financed. On the other hand, accounts payable will also increase as a result of business expansion and this will reduce the net cash needed to finance inventories and accounts receivable. The difference is known as *net change in working capital.* If this difference is positive, an investment in working must be made.

** As the project approaches termination, inventories are sold off and not replaced, and account receivables are eventually collected. As this change occurs, the firm experiences an end-of-project cash flow (known as *working capital recovery*) that is equal to the net working capital investments that were made when the project was begun.

as they occur.) For a small project, either method of timing these flows is satisfactory, because the numerical differences are likely to be insignificant.

- *Financing Activities:* Cash flows classified as financing activities include (1) the amount of borrowing and (2) repayment of principal. Recall that interest payments are tax deductible expenses so that they are usually classified as operating, not financing, activities.

Then, net cash flow for a given year is simply the sum of the net cash flows from these three activities.

Example 17.4.1 — Developing a Cash Flow Statement

A computerized machining center has been proposed for a small tool manufacturing company. If the new system costing $125,000 is installed, it will generate annual revenues of $100,000 and require $20,000 in annual labor, $12,000 in annual material expenses, and another $8000 in annual overhead (power and utility) expenses. The automation facility would be classified as a 7-year MACRS property. The company expects to phase out the facility at the end of 5 years, at which time it will be sold for $50,000. The machining center will require an investment of $23,331 in working capital (mainly spare parts inventory), which will be recovered in full amount at the end of the project life. Assume that $62,500 of the $125,000 paid for the investment is obtained through a bank loan which is to be repaid in equal annual installments at 10% interest over 5 years. The remaining $62,500 will be provided by equity (for example, from retained earnings). Find the year-by-year after-tax net cash flow for the project at a 40% marginal tax rate based on the net income (Approach 1), and determine the after-tax net present worth of the project at the company's MARR of 15%.

Discussion

We will use the business convention that no signs (positive or negative) are used in preparing the income statement, except in the situation where we have a negative taxable income or tax savings. In this situation we will use (   ). However, in preparing the cash flow statement, we will observe explicitly the sign convention: a positive sign indicating cash inflow, a negative sign or (   ) indicating cash outflow.

Solution

Before presenting the cash flow table, we need some preliminary calculations. The following notes explain the essential items in Table 17.4.2.

- *Depreciation Calculation*:

1. If it is held for all 7 years, we depreciate a 7-year property in respective percentages of 14.29, 24.49, 17.49, 12.49, 8.93, 8.92, 8.93, and 4.46% (see Table 17.4.1).
2. If the asset is sold at the end of the fifth tax year (during the recovery period), the applicable depreciation amounts would be $17,863, $30,613, $21,863, $15,613, and $5581. Since the asset is disposed of in the fifth tax year, the last year's depreciation, which would ordinarily be $11,163, is halved due to the half-year convention.

- *Salvage Value and Gain Taxes*: In year 5, we must deal with two aspects of the asset's disposal — salvage value and gains (both ordinary as well as capital). We list the estimated salvage value as a positive cash flow. Taxable gains are calculated as follows:

1. The total depreciation in years 1 to 5 is $17,863 + $30,613 + $21,863 + $15,613 + $5581 = $91,533.
2. The book value at the end of period 5 is the cost base minus the total depreciation, or $125,000 – $91,533 = $33,467.
3. The gains on the sale are the salvage value minus the book value, or $50,000 – $33,467 = $16,533. (The salvage value is less than the cost base, so all the gain is ordinary.)
4. The tax on the ordinary gains is $16,633 × 40% = $6,613. This is the amount that is placed in the table under "gains tax".

- *Interest and principal repayment*: We first need to compute the size of the annual installments:

$$\$62,500(A/P,10\%,5) = \$16,487$$

TABLE 17.4.2 Cash Flow Statement for the Automated Machining Center Project with Debt Financing (Example 17.4.1)

	0	1	2	3	4	5
Income Statement						
Revenues		$100,000	$100,000	$100,000	$100,000	$100,000
Labor		20,000	20,000	20,000	20,000	20,000
Material		12,000	12,000	12,000	12,000	12,000
Overhead		8,000	8,000	8,000	8,000	8,000
Depreciation		17,863	30,613	21,863	15,613	5,581
Debt interest		6,250	5,226	4,100	2,861	1,499
Taxable income		$35,887	$24,161	$34,037	$41,526	$52,920
Income taxes (40%)		14,355	9,664	13,615	16,610	21,168
Net income		$21,532	$14,497	$20,433	$24,916	$31,752
Cash Flow Statement						
Operating activities						
Net income		21,532	14,497	20,422	24,916	31,752
Depreciation		17,863	30,613	21,863	15,613	5,581
Investment activities						
Investment	(125,000)					
Salvage						50,000
Gains tax						(6,613)
Working capital	(23,331)					23,331
Financing activities						
Borrowed funds	62,500					
Principal repayment		(10,237)	(11,261)	(12,387)	(13,626)	(14,988)
Net cash flow	$(85,831)	$29,158	$33,849	$29,898	$26,903	$89,063

Next, we determine the repayment schedule of the loan by itemizing both the interest and the principal represented in each annual repayment as follows:

Year	Beginning Balance	Interest Payment	Principal Payment	Ending Balance
1	$62,500	$6,250	$10,237	$52,263
2	52,263	5,226	11,261	41,002
3	41,002	4,100	12,387	28,615
4	28,615	2,861	13,626	14,989
5	14,989	1,499	14,988	0

The interest payments are listed under the income statement and the principal payments are listed under the cash flow statement as shown in Table 17.4.2.

- *Investment Analysis:* Once we obtain the project's after-tax net cash flows, we can determine their equivalent present worth at the firm's interest rate of 15%. The present value equivalent of the after-tax cash flow series is

$$PW(15\%) = -\$85{,}351 + \$29{,}158(P/F,15\%,1) + \ldots + \$89{,}063(P/F,15\%,5)$$
$$= \$44{,}439$$

This means that investing $125,000 in this automated facility would bring in enough revenue to recover the initial investment and the cost of funds with a surplus of $44,439.

Effects of Inflation on Project Cash Flows

We now introduce inflation into estimating project cash flows. We are especially interested in two elements of project cash flows — depreciation expenses and interest expenses — that are essentially immune to the effects of inflation. We also consider the complication of how to proceed when multiple price indexes have been used in generating various project cash flows.

Because depreciation expenses (as well as loan repayment) are calculated on some base-year purchase amount, they do not increase over time to keep pace with inflation. Thus, they lose some of their value to defer taxes as inflation drives up the general price level and hence taxable income. Similarly, salvage values of depreciable assets can increase with the general inflation rate and, because any gains on salvage values are taxable, they can result in increased taxes.

Example 17.4.2 — After-Tax Cash Flows under Inflation

A construction firm is offered a fixed-price contract for a 5-year period. The firm will be paid $23,500 (actual dollars) per year for the contract period. In order to accept the contract, the firm must purchase equipment costing $15,000 and requiring $13,000 (constant dollars) per year to operate. The equipment qualifies for 5-year MACRS depreciation and is expected to have a salvage value of $1000 at the end of 5 years. Use a tax rate of 40% and an inflation-free interest rate of 20%. If the general inflation rate $(\bar{f})$ is expected to average 5% over the next 5 years, salvage value at the annual rate of 5%, and operating expenses at 8% per year for the project duration, should the contractor accept the contract?

Solution

The analysis of this situation should explicitly consider inflation, since the contractor is being offered a fixed-price contract and cannot increase the fee to compensate for increased costs. In this problem, as is common practice, we assume that all estimated costs are expressed in today's dollars, and actual costs will be increased due to inflation.

The Excel spreadsheet analysis is shown in Table 17.4.3, where the first five rows are designated as the input fields. Then column C in both the income statement and the cash flow statement is reserved for entering the specific inflation rate for the item listed in that row. Since the O&M costs are responsive to inflation, we can automate the cell entries by using the following cell formulas:

$$\text{cell E12} = \$D\$2^{*}(1 + \$C\$12)$$

$$\text{cell F12} = \text{E12}^{*}(1 + \$C\$12)$$

$$\vdots \qquad \vdots$$

$$\text{cell I12} = \text{H12}^{*}(1 + \$C\$12)$$

Note that the salvage value in cell I27 has been increased at 5%. (When no inflation rate is given for a specific cost category, it is normally assumed that the general inflation rate holds.) Gains taxes on disposal are based on the difference between book value and salvage value, in this case, $1276 – $1728 = ($452) or loss of $452. This results in a tax savings of ($452) (0.40) = $181, as shown in cell I28.

In row 12, operating expenses have been increased at 8%. As explained in the section "Loss of Purchasing Power," actual-dollar cash flows are converted to constant-dollar flows by "deflating" at the general inflation rate. The IRR is calculated at 22.03%, based on the constant-dollar cash flows. This is compared to the MARR of 20%, the inflation-free interest rate, indicating that this is an acceptable contract as long as the 5 and 8% escalation rates are correct.

Since no one can predict inflation rates in any precise manner, it is always wise to investigate the effects of changes in these rates. This is very easy to do with a spreadsheet. For example, we can easily determine the value of the general inflation rate at which this project exactly earns 20%. The value of $\bar{f}$ was adjusted manually until the IRR was exactly 20%. This would not be a good project if $\bar{f}$ were greater than 6.77%

TABLE 17.4.3 Excel's Spreadsheet Application to "What If" Questions — What General Inflation Rate Does the Project Break Even? (Example 17.15)

	A	B	C	D	E	F	G	H	I
1									
2		INPUT:	O&M Cost	$ 13,000		General Inflation Rate		5.00%	
3			Salvage	$ 1,000		Inflation-Free Interest		20.00%	
4			Contract $	$ 23,000		Market Interest Rate		26.00%	
5			Investment	$ 15,000		Income Tax Rate		40.00%	
6									
7			Inflation Rate	0	1	2	3	4	5
8		Income Statement							
9									
10		Revenues			$ 23,500	$ 23,500	$ 23,500	$ 23,500	$ 23,500
11		Expenses:							
12		O&M	8%		14,040	15,163	16,376	17,686	19,101
13		Depreciation			3,000	4,800	2,880	1,728	864
15		Taxable Income			$ 6,460	$ 3,537	$ 4,244	$ 4,086	$ 3,535
16		Income Taxes (40%)			2,584	1,415	1,697	1,634	1,414
18		Net Income			$ 3,876	$ 2,122	$ 2,546	$ 2,451	$ 2,121
19									
20		Cash Flow Statement							
21									
22		Operating Activities:							
23		Net Income			3,876	2,122	2,546	2,451	2,121
24		Depreciation			3,000	4,800	2,880	1,728	864
25		Investment Activities:							
26		Investment		(15,000)					
27		Salvage	5%						1,276
28		Gains Tax							181
30		Net Cash Flow		$ (15,000)	$ 6,876	$ 6,922	$ 5,426	$ 4,179	$ 4,442
31		(in actual dollars)							
32		Net Cash Flow		$ (15,000)	$6,549	$6,279	$4,687	$3,438	$3,480
33		(in constant dollars)							
34		Equ. Present Worth		$ (15,000)	$5,457	$4,360	$2,713	$1,658	$1,399
36		Net Present Worth	$587						
37		Internal Rate of Return	22.03%						

(cell H2). (Note that at the exact value of $\bar{f}$ (6.771%), the NPW in cell C36 will be zero or its rate of return would be 20%.) Similarly, you can vary the O&M cost and salvage value to see how the project's profitability changes.

17.5 Sensitivity and Risk Analysis

In previous sections, the cash flows from projects were assumed to be known with complete certainty, and our analysis was concerned with measuring the economic worth of projects and selecting the best investment projects. Although these results can provide reasonable decision bases for many investment situations, we should certainly consider the more usual situation where forecasts of cash flows are subject to some degree of uncertainty. In this situation, management rarely has precise expectations regarding the future cash flows to be derived from a particular project. In fact, the best that the firm can reasonably expect to do is to estimate the range of possible future costs and benefits and the relative chances of achieving a certain return on the investment. We can use the term risk in describing an investment project whose cash flow is not known in advance with absolute certainty, but for which an array of alternative outcomes and their probabilities (odds) are known. We will also use the term project risk to refer to the variability in a project's NPW. A greater project risk means that there is a greater variability in the project's NPW, or simply saying that *risk is the potential for loss*. We may begin analyzing project risk by first determining the uncertainty inherent in a project's cash flows. We can consider risk in a number of ways ranging from making informal judgments to calculating complex economic and statistical analyses. In this section, we will introduce three methods of describing project risk: (1) sensitivity analysis, (2) scenario analysis, and (3) risk analysis. We shall explain each method with a single example (Boston Metal Company).

Project Risk

The decision to make a major capital investment such as the introduction of a new product requires cash flow information over the life of the project. The profitability estimate of the investment depends on cash flow estimations, which are generally uncertain. Many cash flow elements (such as demand) are subject to substantial uncertainty. The common approach is to make single-number "best estimates" for each of the uncertain factors and then to calculate measures of profitability such as NPW or rate of return for the project. This approach has two drawbacks:

1. There is no guarantee that the "best estimates" will ever match actual values.
2. There is no way to measure the risk associated with the investment or the project risk. In particular, the manager has no way of determining either the probability that the project will lose money or the probability that it will generate very large profits.

Because cash flows can be so difficult to estimate accurately, project managers frequently consider a range of possible values for cash flow elements. If there is a range of possible values for individual cash flows, it follows that there is a range of possible values for the NPW of a given project. Clearly, the analyst will want to try to gauge the probability and reliability of individual cash flows occurring and, consequently, the level of certainty about achieving the overall project worth.

Sensitivity Analysis

One way to glean a sense of the possible outcomes of an investment is to perform a sensitivity analysis. This analysis determines the effect on NPW of variations in the input variables (such as revenues, operating cost, and salvage value) used to estimate after-tax cash flows. A *sensitivity analysis* reveals how much the NPW will change in response to a given change in an input variable. In a calculation of cash flows, some items have a greater influence on the final result than others. In some problems, we may easily identify the most significant item. For example, the estimate of sales volume is often a major factor in a problem in which the quantity sold varies among the alternatives. In other problems, we may want to locate the items that have an important influence on the final results so that they can be subjected to special scrutiny.

Sensitivity analysis is sometimes called "what-if" analysis because it answers questions such as: What if incremental sales are only 1000 units, rather than 2000 units? Then what will the NPW be? Sensitivity analysis begins with a base-case situation, which is developed using the most-likely values for each input. Then we change the specific variable of interest by several specific percentages above and below the most-likely value, holding other variables constant. Next, we calculate a new NPW for each of these values. A convenient and useful way to present the results of a sensitivity analysis is to plot *sensitivity graphs*. The slopes of the lines show how sensitive the NPW is to changes in each of the inputs: the steeper the slope, the more sensitive the NPW is to a change in the particular variable. It identifies the crucial variables that affect the final outcome most. We will use Example 17.5.1 to illustrate the concept of sensitivity analysis.

Example 17.5.1 — Sensitivity Analysis

Boston Metal Company (BMC), a small manufacturer of fabricated metal parts, must decide whether to enter the competition to be the supplier of transmission housings for Gulf Electric. Gulf Electric has its own in-house manufacturing facility to produce transmission housings, but it has almost reached its maximum production capacity. Therefore, Gulf is looking for an outside supplier. To compete, the firm must design a new fixture for the production process and purchase a new forge. The new forge would cost $125,000, including tooling costs for the transmission housings. If BMC gets the order, it may be able to sell as many as 2000 units per year to Gulf Electric for $50 each, and the variable production costs,* such as direct labor and direct material costs, will be $15 per unit. The increase in fixed costs** other than depreciation will amount to $10,000 per year. The firm expects that the proposed transmission-housings project would have about a 5-year product life. The firm also estimates that the amount ordered by Gulf Electric for the first year will be ordered in each of the subsequent 4 years. (Due to the nature of contracted production, the annual demand and unit price would remain the same over the project after the contract is signed.) The initial investment can be depreciated on a MACRS basis over the 7-year period, and the marginal income tax rate is expected to remain at 40%. At the end of 5 years, the forge machine is expected to retain a market value of about 35% of the original investment. Based on this information, the engineering and marketing staffs have prepared the cash flow forecasts shown in Table 17.5.1. Since NPW is positive ($40,169) at the 15% opportunity cost of capital (MARR), the project appears to be worth undertaking.

However, BMC's managers are uneasy about this project because there are too many uncertain elements that have not been considered in the analysis. If decided, BMC must make the investment in the forging machine to provide some samples with Gulf Electric as a part of the bidding process. If Gulf Electric does not like BMC's sample, BMC stands to lose the entire investment in the forging machine. On the other hand, if Gulf likes BMC's sample but it is overpriced, BMC would be under pressure to bring the price in line with competing firms. There is even a possibility that BMC would get a smaller order as Gulf may utilize their overtime capacity to produce some extra units. They also are not certain about the variable and fixed cost figures. Recognizing these uncertainties, the managers want to assess the various potential future outcomes before making a final decision. (a) Perform a sensitivity analysis to each variable and (b) develop a sensitivity graph.

Discussion

Table 17.5.1 shows BMC's expected cash flows — but there is no guarantee that they will indeed materialize. BMC is not particularly confident in is revenue forecasts. The managers think that if competing firms enter the market, BMC will lose a substantial portion of the projected revenues. Before undertaking the project described, the company wants to identify the key variables that determine whether the project will succeed or fail. The marketing department has estimated revenue as follows:

$$\begin{aligned}\text{annual revenue} &= (\text{product demand})(\text{unit price})\\ &= (2000)(\$50) = \$100{,}000\end{aligned}$$

The engineering department has estimated variable costs such as labor and material per unit at $15. Since the projected sales volume is 2000 units per years, the total variable cost is $30,000.

Having defined the unit sales, unit price, unit variable cost, and fixed cost, we conduct a sensitivity analysis with respect to these key input variables. This is done by varying each of the estimates by a given percentage and determining what effect the variation in that item has on the final results. If the effect is large, the result is sensitive to that item. Our objective is to locate the most sensitive item(s).

---

* Expenses that change in direct proportion to the change in volume of sales or production.

** Expenses that do not vary as the volume of sales or production changes. For example, property taxes, insurance, depreciation, and rent are usually fixed expenses.

TABLE 17.5.1 A Typical Excel Worksheet Design to Perform Sensitivity Analyses (Example 17.5.1)

	A	B	C	D	E	F	G	H
1

Solution

(a) *Sensitivity analysis:* We begin the sensitivity analysis with a "base-case" situation, which reflects the best estimate (expected value) for each input variable. In developing Table 17.5.2, we changed a given variable by 20% in 5% increments, above and below the base-case value, and calculated new NPWs, holding other variables constant. The values for both sales and operating costs were the expected, or base-case, values, and the resulting $40,169 is called the base-case NPW. Now we ask a series of "what-if" questions: What if sales are 20% below the expected level? What if operating costs rise? What if the unit price drops from $50 to $45? Table 17.5.2 summarizes the results of varying the values of the key input variables.

(b) *Sensitivity graph:* Figure 17.5.1 shows the transmission project's sensitivity graphs for six of the key input variables. The base-case NPW is plotted on the ordinate of the graph at the value 1.0 on the abscissa. Next, the value of product demand is reduced to 0.95 of its base-case value, and

TABLE 17.5.2 Sensitivity Analysis for Six Key Input Variables (Example 17.5.1)

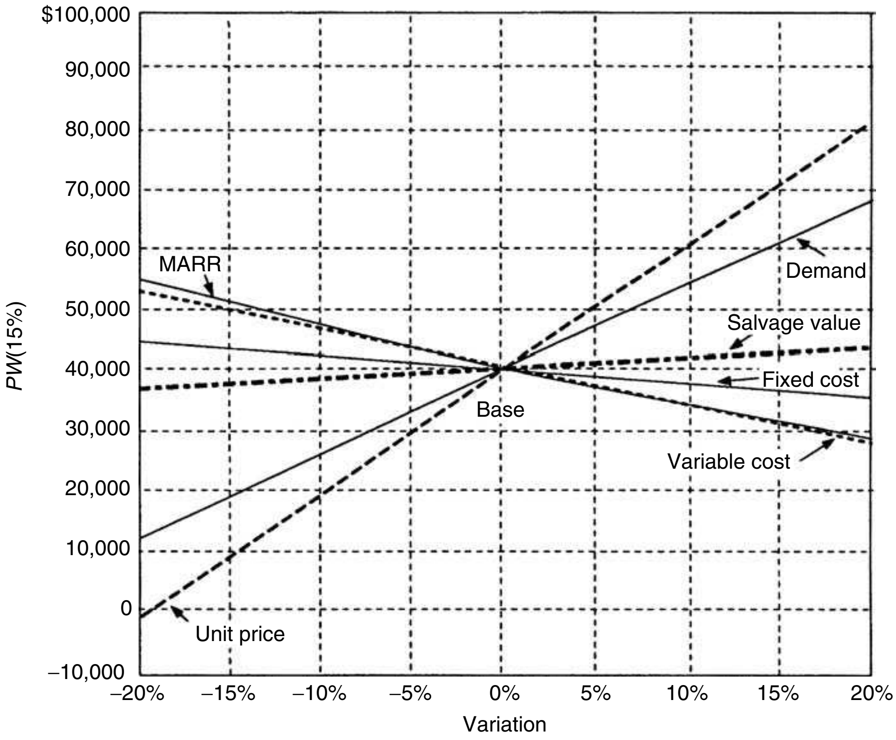

FIGURE 17.5.1 Sensitivity graph — BMC's transmission-housings project (Example 17.5.1).

the NPW is recomputed with all other variables held at their base-case value. We repeat the process by either decreasing or increasing the relative deviation from the base case. The lines for the variable unit price, variable unit cost, fixed costs, and salvage value are obtained in the same manner. In Figure 17.5.1, we see that the project's NPW is very sensitive to changes in product demand and unit price, is fairly sensitive to changes in the variable costs, and is relatively insensitive to changes in the fixed cost and the salvage value.

Graphic displays such as those in Figure 17.5.1 provide a useful means to communicate the relative sensitivities of the different variables on the corresponding NPW value. However, the sensitivity graph does not explain any variable interactions among the variables or the likelihood of realizing any specific deviation from the base case. Certainly, it is conceivable that an answer might not be very sensitive to changes in either of the two items, but very sensitive to combined changes in them.

Scenario Analysis

Although sensitivity analysis is useful, it does have limitations. It is often difficult to specify precisely the relationship between a particular variable and the NPW. The relationship is further complicated by interdependencies among the variables. Holding operating costs constant while varying unit sales may ease the analysis, but in reality, operating costs do not behave in that manner. Yet it may complicate the analysis too much to permit movement in more than one variable at a time. A scenario analysis is a technique that does consider the sensitivity of NPW both to changes in key variables and to the range of likely variable values. For example, the decision-maker may consider two extreme cases, a "worst-case" scenario (low unit sales, low unit price, high variable cost per unit, high fixed cost, and so on) and a "best-case" scenario. The NPWs under the worst and best conditions are then calculated and compared to the expected, or base-case, NPW. Example 17.5.2 will illustrate a plausible scenario analysis for the BMC's transmission-housings project.

TABLE 17.5.3 Scenario Analysis for BMC (Example 17.5.2)

Variable Considered	Worst-Case Scenario	Most-Likely-Case Scenario	Best-Case Scenario
Unit demand	1,600	2,000	2,400
Unit price ($)	48	50	53
Variable cost ($)	17	15	12
Fixed cost ($)	11,000	10,000	8,000
Salvage value ($)	30,000	40,000	50,000
PW (15%)	–$5,856	$40,169	$104,295

Example 17.5.2 — Scenario Analysis

Consider again BMC's transmission-housing project in Example 17.5.2. Assume that the company's managers are fairly confident of their estimates of all the projects's cash flow variables except that for unit sales. Further, assume that they regard a decline in unit sales to below 1600 or a rise above 2400 as extremely unlikely. Thus, decremental annual sales of 400 units define the lower bound, or the worst-case scenario, whereas incremental annual sales of 400 units define the upper bound, or the best-case scenario. (Remember that the most-likely value was 2000 in annual unit sales.) Discuss the worst- and best-case scenarios, assuming that the unit sales for all 5 years would be equal.

Discussion

To carry out the scenario analysis, we ask the marketing and engineering staffs to give optimistic (best-case) and pessimistic (worst-case) estimates for the key variables. Then we use the worst-case variable values to obtain the worst-case NPW and the best-case variable values to obtain the best-case NPW. Table 17.5.3 summarizes the results of our analysis. We see that the base case produces a positive NPW, the worst case produces a negative NPW, and the best case produces a large positive NPW.

By just looking at the results in Table 17.5.3, it is not easy to interpret scenario analysis or to make a decision based on it. For example, we can say that there is a chance of losing money on the project, but we do not yet have a specific probability for this possibility. Clearly, we need estimates of the probabilities of occurrence of the worst case, the best case, the base case (most likely), and all the other possibilities. This need leads us directly to the next step, developing a probability distribution. If we can predict the effects on the NPW of variations in the parameters, why should we not assign a probability distribution to the possible outcomes of each parameter and combine these distributions in some way to produce a probability distribution for the possible outcomes of the NPW? We shall consider this issue in the next section.

Risk Analysis

Quantitative statements about risk are given as numerical probabilities, or as values for likelihoods (odds) of occurrence. Probabilities are given as decimal fractions in the interval 0.0 to 1.0. An event or outcome that is certain to occur has a probability of 1.0. As the probability of an event approaches 0, the event becomes increasingly less likely to occur. The assignment of probabilities to the various outcomes of an investment project is generally called *risk analysis*. In this section, we shall assume that the analyst has available the probabilities (likelihoods) of future events from either previous experience in a similar project or a market survey. The use of probability information can provide management with a range of possible outcomes and the likelihood of achieving different goals under each investment alternative.

Procedure for Developing an NPW Distribution

To develop the NPW distribution, we may follow these steps:

1. Identify all cash flows elements that are random variables. (A *random variable*) is a variable that can have more than one possible value.)
2. Express the NPW (or cash flow series) as a function of random variables.

3. Determine the probability distribution for each random variable.
4. Determine the joint events and their probabilities.
5. Evaluate the NPW equation at these joint events.
6. Order the NPW values in increasing order of NPW.

These steps can best be illustrated by Example 17.5.3.

Example 17.5.3 — Developing an NPW Probability Distribution

Consider the BMC's transmission-housing project. If the unit sales (X) and unit price (Y) were to vary with the following probabilities, determine the NPW probability distribution. Here we assume the situation where both random variables are independent. In other words, observing a typical outcome for random variable X does not have any influence on predicting the outcome for random variable Y.

Demand (X)	Probability	Unit Price (Y)	Probability
1600	0.20	$48	0.30
2000	0.60	$50	0.50
2400	0.20	$53	0.20

Discussion

If the product demand X and the unit price Y are independent random variables, the PW (15%) will also be a random variable. To determine the NPW distribution, we need to consider all the combinations of possible outcomes. The first possibility is the event where x = 1600 and y = $48. With these values as input in Table 17.5.1, we compute the resulting NPW outcome to be $5574. Since X and Y are considered to be independent random variables, the probability of this joint event is

$$\begin{aligned} P(x=1600, y=\$48) &= P(x=1600)\,P(y=\$48) \\ &= (0.20)(0.30) \\ &= 0.06 \end{aligned}$$

There are eight other possible joint outcomes. Substituting these pairs of values in Table 17.5.1, we obtain the NPWs and their joint probabilities in Table 17.5.4 and its NPW distribution as depicted in Figure 17.5.2.

Solution

The NPW probability distribution in Table 17.5.4 indicates that the project's NPW varies between $5574 and $82,808, but that there is no loss under any of the circumstances examined. From the cumulative distribution, we further observe that there is a 0.38 probability that the project would realize an NPW

TABLE 17.5.4 The NPW Probability Distribution with Independent Random Variables (Example 17.5.3)

Event No.	x	y	P(x,y)	Cumulative Joint Probability	NPW
1	1600	$48.00	0.06	0.06	$5,574
2	1600	$50.00	0.10	0.16	$12,010
3	1600	$53.00	0.04	0.20	$21,664
4	2000	$48.00	0.18	0.38	$32,123
5	2000	$50.00	0.30	0.68	$40,168
6	2000	$53.00	0.12	0.80	$52,236
7	2400	$48.00	0.06	0.86	$58,672
8	2400	$50.00	0.10	0.96	$68,326
9	2400	$53.00	0.04	1.00	$82,808

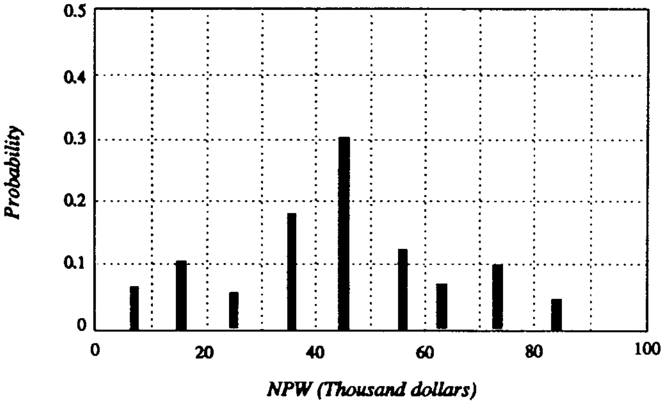

FIGURE 17.5.2 NPW probability distributions: when X and Y are independent (Example 17.5.3).

less than that forecast for the base-case situation ($40,168). On the other hand, there is a 0.32 probability that the NPW will be greater than this value. Certainly, the probability distribution provides much more information on the likelihood of each possible event, as compared with the scenario analysis presented in Table 17.5.3.

Expected Value and Variance

We have developed a probability distribution for the NPW by considering the random cash flows. As we have observed, the probability distribution helps us to see what the data imply in terms of the risk of the project. With the NPW distribution defined, we can further summarize the probabilistic information — the mean and the variance.

The expected value (also called the *mean*) is a weighted average value of the random variable (μ) where the weighting factors are the probabilities of occurrence. (See Table 17.5.5.) The expected value of a distribution tells us important information about the "average" or expected value of a random variable such as the NPW, but it does not tell us anything about the variability on either side of the expected value. Will the range of possible values of the random variable be very small, with all the values located at or near the expected value?

Another measure that we need in analyzing probabilistic situations is a measure of the risk due to the variability of the outcomes. There are several measures of the variation of a set of numbers that are used in statistical analysis — the range and the variance (or standard deviation), among others. The variance and the standard deviation are used most commonly in the analysis of risk situations. We will use Var[X] or σ_x^2 to denote the variance, and σ_x to denote the standard deviation of random variable X. (If there is only one random variable in an analysis, we normally omit the subscript.) The variance tells us the degree of spread, or dispersion, of the distribution on either side of the mean value. As the variance increases, the spread of the distribution increases; the smaller the variance, the narrower the spread about the expected value.

To determine the variance, we first calculate the deviation of each possible outcome x_j from the expected value ($x_j - \mu$), then raise the result to the second power and multiply it by the probability of x_j occurring (that is, p_j). The summation of all these products serves as a measure of the distribution's variability. To be most useful, any measure of risk should have a definite value (unit). One such measure is the standard deviation. To calculate the standard deviation, we take the positive square root of Var[X], which is measured in the same units as is X. The standard deviation is a probability-weighted deviation (more precisely, square root of sum of squared deviations) from the expected value. Thus, it gives us an idea of how far above or below the expected value the actual value is likely to be. For most probability distributions, the actual value will be observed within the $\pm 3\sigma$ range. In our BMC project, we obtain the variance of the NPW distribution, assuming independence between X and Y, as shown in Table 17.5.5.

TABLE 17.5.5 Calculation of the Mean and Variance of NPW Distribution (Example 17.5.3)

Event No.	x	y	P(x,y)	Cumulative Joint Probability	NPW	Weighted NPW
1	1600	$48.00	0.06	0.06	$5,574	$334
2	1600	$50.00	0.10	0.16	$12,010	$1,201

6	2000	$53.00	0.12	0.80	$52,236	$6,268
7	2400	$48.00	0.06	0.86	$58,672	$3,520
8	2400	$50.00	0.10	0.96	$68,326	$6,833
9	2400	$53.00	0.04	1.00	$82,808	$3,312
						E(NPW) = $40,168

Event No.	x	y	P(x,y)	NPW	(NPW – E[NPW])^2	Weighted (NPW – E[NPW])^2
1	1600	$48.00	0.06	$5,574	1,196,769,744	71,806,185
2	1600	$50.00	0.10	$12,010	792,884,227	79,288,423
3	1600	$53.00	0.04	$21,664	342,396,536	13,695,861
4	2000	$48.00	0.18	$32,123	64,725,243	11,650,544
5	2000	$50.00	0.30	$40,168	0	0
6	2000	$53.00	0.12	$52,236	145,631,797	17,475,816
7	2400	$48.00	0.06	$58,672	342,396,536	20,543,792
8	2400	$50.00	0.10	$68,326	792,884,227	79,288,423
9	2400	$53.00	0.04	$82,808	1,818,132,077	72,725,283
						Var[PW(15%)] = 366,474,326
						Standard Deviation = $19,144

Decision Rule

Once the expected value has been located from the NPW distribution, it can be used to make an accept-reject decision, in much the same way that a single NPW is used when a single possible outcome is considered for an investment project. The decision rule is called the *expected value criterion*, and using it we may accept a single project if its expected NPW value is positive. In the case of mutually exclusive alternatives, we select the one with the highest expected NPW. The use of expected NPW has an advantage over the use of a point estimate, such as the likely value, because it includes all the possible cash flow events and their probabilities.

The justification for the use of the expected value criterion is based on the *law of large numbers,* which states that if many repetitions of an experiment are performed, the average outcome will tend toward the expected value. This justification may seem to negate the usefulness of the expected value criterion in economic analysis, since most often in project evaluation we are concerned with a single, nonrepeatable "experiment" — that is, investment alternative. However, if a firm adopts the expected value criterion as a standard decision rule for *all* its investment alternatives, over the long term the law of large numbers predicts that accepted projects will tend to meet their expected values. Individual projects may succeed or fail, but the average project result will tend to meet the firm's standard for economic success.

The expected-value criterion is simple and straightforward to use, but it fails to reflect the variability of investment outcome. Certainly, we can enrich our decision by incorporating the variability information along with the expected value. Since the variance represents the dispersion of the distribution, it is desirable to minimize it. In other words, the smaller the variance, the less the variability (the potential for loss) associated with the NPW. Therefore, when we compare the mutually exclusive projects, we may select the alternative with the smaller variance if its expected value is the same as, or larger than, those of other alternatives. In cases where there are no clear-cut preferences, the ultimate choice will depend on the decision-maker's trade-offs — how much he or she is willing to take the variability to achieve a higher expected value. In other words, the challenge is to decide what level of risk you are willing to accept and then, having decided on your risk tolerance, to understand the implications of that choice.

17.6 Design Economics

Engineers frequently have to come up with a minimum-cost solution when they have two or more cost components that are affected differently by the same design element. That is, for a single design variable, some costs increase while others decrease. Another valuable extension of the AE analysis in the section on "Annual Equivalent Method," is that these cost components be expressed in equivalent annual form so that we can identify which cost component we need to control to obtain the minimum cost solution to various engineering design problems.

Capital Costs vs. Operating Costs

The AE method is sometimes called the annual equivalent cost method when only costs are involved. In this case, there are two kinds of costs that revenues must cover: *operating costs* and *capital costs*. Operating costs are incurred by the operation of physical plant or equipment to provide service; they include such items as labor and raw materials. Capital costs are incurred by purchasing the assets used in production and service. Normally, capital costs are nonrecurring (that is, one-time costs), whereas operating costs recur as long as the asset is owned.

Because operating costs recur over the life of a project, they tend to be estimated on an annual basis anyway, so for the purposes of an annual equivalent cost analysis, they require no special calculation on our part. However, because capital costs tend to be one-time costs in conducting an annual equivalent cost analysis, we must translate this one-time cost into its annual equivalent over the life of the project. The annual equivalent of a capital cost is given a special name: *capital recovery cost*, designated CR(i).

There are two general monetary transactions associated with the purchase and eventual retirement of a capital asset, its initial cost (I) and its salvage value (S). Taking into account these sums, we calculate the capital recovery cost as

$$CR(i) = I(A/P,i,N) - S(A/F,i,N) \tag{17.6.1}$$

Recalling the algebraic relationships between factors in Table 17.1.1, notice that the (A/P,*i*,N) factor can be expressed as

$$(A/P,i,N) = (A/F,i,N) + i$$

Then, we may rewrite the CR(*i*) as

$$\begin{aligned} CR(i) &= I(A/P,i,N) - S[(A/P,i,N) - i] \\ &= (I - S)(A/P,i,N) + iS \end{aligned} \tag{17.6.2}$$

Minimum-Cost Function

When the equivalent annual total cost of a design variable is a function of increasing (O&M costs) and decreasing cost components (capital costs), we usually can find the optimal value that will minimize its cost.

$$AE(i) = a + bx + \frac{c}{x} \tag{17.6.3}$$

where x is a common design variable, and a, b, and c are constants.

To find the value of the common design variable that minimizes the AE(*i*), we need to take the first derivative, equate the result to zero, and solve for x.

$$\frac{dAE(i)}{dx} = b - \frac{c}{x^2} \tag{17.6.4}$$

$$= 0$$

$$x^* = \sqrt{\frac{c}{b}}$$

The value x^* is the minimum cost point for the design alternative. To illustrate the optimization concept, we will consider selecting an optimal pipe size.

Example 17.6.1 — Economical Pipe Size

As a result of the conflict in the Persian Gulf, Kuwait is studying the feasibility of running a steel pipeline across the Arabian Peninsula to the Red Sea. The pipeline will be designed to handle 3 million barrels of crude oil per day at optimum conditions. The length of the line will be 600 miles. Calculate the optimum pipeline diameter that will be used for 20 years for the following data at $i = 10\%$:

- Pumping power = $1.333Q\Delta P/1{,}980{,}000$ horsepower
- Q = volume flow rate, cubic ft/hr
- $\Delta P = 128Q\mu L/g\pi D^4$, pressure drop lb/sq ft
- L = pipe length, ft
- D = inside pipe diameter, ft
- t = 0.01 D, pipeline wall thickness, ft
- $\mu = 8500$ lb/hr ft, oil viscosity
- $g = 32.2 \times 12{,}960{,}000$ ft/hr^2
- Power cost, \$0.015 per horsepower hour
- Oil cost, \$18 per barrel
- Pipeline cost, \$1.00 per pound of steel
- Pump and motor costs, \$195 per horsepower

The salvage value of the steel after 20 years is assumed to be zero considering the cost of removal. (See Figure 17.6.1 for relationship between D and t.)

Discussion

In general, when progressively larger-size pipe is used to carry a given fluid at a given volume flow rate, the energy required to move the fluid will progressively decrease. However, as we increase the pipe size, the cost to construct the pipe will increase. In practice, to obtain the best pipe size for a particular situation, you may choose a reasonable, but small, starting size. Compute the energy cost of pumping fluid through this size and the total construction cost. Compare the difference in energy cost with the difference in construction cost. When the savings in energy cost exceed the added construction cost, you may repeat the process with progressively larger pipe sizes until the added construction cost exceeds the savings in energy cost. As soon as this happens the best pipe size to use in the particular application is identified. However, we can simplify this search process by using the minimum cost concept as explained through Equation (17.6.3) and Equation (17.6.4).

Solution

We will solve the pipe sizing problem in 8 steps:

1. Since the pipe size will be measured in inches, we will assume the following basic conversion units:
    - 1 mile = 5280 ft
    - 600 miles = $600 \times 5280 = 3{,}168{,}000$ ft
    - 1 barrel = 42 U.S. gal
    - 1 barrel = $42 \text{ gal} \times 231 \text{ in.}^3/\text{gal} = 9702 \text{ in.}^3$
    - 1 barrel = $9702 \text{ in.}^3/12^3 = 5.6146 \text{ ft}^3$
    - Density of steel = 490.75 lb/ft^3

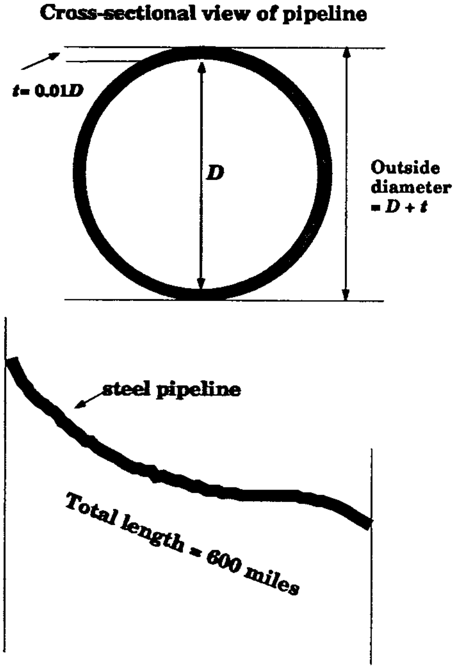

FIGURE 17.6.1 Designing economical pipe size to handle 3 million barrels of crude oil per day (Example 17.6.1).

2. To determine the operating cost in pumping oil, we first need to determine power (electricity) required to pump oil:
   - Volume flow rate per hour:

$$Q = 3{,}000{,}000 \text{ barrels/day} \times 5.6146 \text{ ft}^3/\text{barrel}$$

$$= 16{,}843{,}800 \text{ ft}^3/\text{day}$$

$$= 701{,}825 \text{ ft}^3/\text{hr}$$

   - Pressure drop:

$$\Delta P = \frac{128 Q \mu L}{g \pi D^4}$$

$$= \frac{128 \times 701{,}825 \times 8500 \times 3{,}168{,}000}{32.2 \times 12{,}960{,}000 \times 3.14159 D^4}$$

$$= \frac{1{,}845{,}153{,}595}{D^4} \text{ lb/ft}^2$$

   - Pumping power required to boost the pressure drop:

$$\text{power} = \frac{1.333 Q \Delta P}{1{,}980{,}000}$$

$$= \frac{1.333 \times 701{,}825 \times \dfrac{1{,}845{,}153{,}595}{D^4}}{1{,}980{,}000}$$

$$= \frac{871{,}818{,}975}{D^4} \text{ hp}$$

- Power cost to pump oil:

$$\text{power cost} = \frac{871{,}818{,}975}{D^4}\,\text{hp} \times \$0.015/\text{hp.hr} \times 24\ \text{hr/day} \times 365\ \text{days/year}$$

$$= \frac{\$114{,}557{,}013{,}315}{D^4}\Big/\text{year}$$

3. Pump and motor cost calculation

$$\text{pump and motor cost} = \frac{871{,}818{,}975}{D^4} \times \$195/\text{hp}$$

$$= \frac{\$170{,}004{,}700{,}125}{D^4}$$

4. Required amount and cost of steel

$$\begin{aligned}
\text{cross-sectional area} &= \frac{3.14159\left[(0.51D)^2 - (0.50D)^2\right]}{4} \\
&= 0.032D^2\ \text{ft}^2 \\
\text{total volume of pipe} &= 0.032D^2\ \text{ft}^2 \times 3{,}168{,}000\ \text{ft} \\
&= 101{,}376D^2\ \text{ft}^3 \\
\text{total weight of steel} &= 101{,}376D^2\ \text{ft}^3 \times 490.75\ \text{lb/ft}^3 \\
&= 49{,}750{,}272D^2\ \text{lb} \\
\text{total pipeline cost} &= \$1.00/\text{lb} \times 49{,}750{,}272D^2\ \text{lb} \\
&= \$49{,}750{,}272D^2
\end{aligned}$$

5. Annual equivalent cost calculation

$$\text{capital cost} = \left(\$49{,}750{,}272D^2 + \frac{\$170{,}004{,}700{,}125}{D^4}\right)(A/P,10\%,20)$$

$$= 5{,}843{,}648D^2 + \frac{19{,}968{,}752{,}076}{D^4}$$

$$\text{annual power cost} = \frac{\$114{,}557{,}013{,}315}{D^4}$$

6. Economical pipe size

$$AE(10\%) = 5{,}843{,}648D^2 + \frac{19{,}968{,}752{,}076}{D^4} + \frac{\$114{,}557{,}013{,}315}{D^4}$$

To find the optimal pipe size (D) that results in the minimum annual equivalent cost, we take the first derivative of AE(10%) with respect to D, equate the result to zero, and solve for D.

$$\frac{dAE(10\%)}{dD} = 11{,}687{,}297D - \frac{538{,}103{,}061{,}567}{D^5}$$

$$= 0$$

$$11{,}687{,}297D^6 = 538{,}103{,}061{,}567$$

$$D^6 = 46{,}041.70$$

$$D^* = \mathbf{5.9868\ ft}$$

Note that velocity in a pipe should be ideally no more than around 10 ft/sec due to friction wearing in the pipe. To check to see if the answer is reasonable, we may compute

$$Q = \text{velocity} \times \text{pipe inner area}$$

$$701{,}825\ \text{ft}^3/\text{hr} \times \frac{1}{3{,}600}\ \text{hr/sec} = V\frac{3.14159(5.9868)^2}{4}$$

$$V = 6.93\ \text{ft/sec}$$

which is less than 10 ft/sec. Therefore, the optimal answer as calculated can be practical.

7. Equivalent annual cost at optimal pipe size
   - Capital cost:

$$\text{capital cost} = \left[\$49{,}750{,}272(5.9868)^2 + \frac{170{,}004{,}700{,}125}{5.9868^4}\right](A/P, 10\%, 20)$$

$$= 5{,}843{,}648(5.9868)^2 + \frac{19{,}968{,}752{,}076}{5.9868^4}$$

$$= \mathbf{\$224{,}991{,}039}$$

   - Annual power cost:

$$\text{annual power cost} = \frac{114{,}557{,}013{,}315}{5.9868^4}$$

$$= \mathbf{\$89{,}174{,}911}$$

   - Total annual equivalent cost:

$$\text{total annual cost} = \$224{,}991{,}039 + \$89{,}174{,}911$$

$$= \mathbf{\$314{,}165{,}950}$$

8. Total annual oil revenue

$$\text{annual oil revenue} = \$18/\text{bbl} \times 3{,}000{,}000\ \text{bbls/day} \times 365\ \text{days/year}$$

$$= \$19{,}710{,}000{,}000/\text{year}$$

There are enough revenues to offset the capital as well as operating cost.

Comments

A variety of other criteria exists for choosing pipe size for a particular fluid transfer application. For example, low velocity may be required where there are erosion or corrosion concerns. Alternatively, higher velocities may be desirable for slurries where setting is a concern. Constructional ease will also weight significantly in the choice of pipe size. A small pipe size may not accommodate the head and flow requirements efficiently, whereas space limitations may prohibit selecting large pipe size.

17.7 Project Management

Donald D. Tippett

Engineers, Projects, and Project Management

For a majority of engineers, project work is a way of life throughout their professional careers. Projects build bridges, put humans in space, design and install computer-integrated manufacturing systems, perform research and development (R&D) on state-of-the-art materials, and pursue a thousand other objectives in organizations large and small across the world.

A project has a specific set of objectives and a definite schedule, budget, and set of performance requirements. It has a finite life span and is usually a team effort led by a recognized project manager.

Project management is planning, organizing, leading, and controlling organizational resources to successfully complete the project objectives.

Project Planning

It could be argued that the two most important facets of project management are planning and team building (to be discussed in the section on team building).

What Is Project Planning?

Planning is determining what needs to be done, by whom, and by when.
Planning is decision making based on futurity.
Planning is selecting enterprise objectives, and establishing policies/procedures/programs necessary for achieving them.
Planning is an iterative process and must be performed throughout the life of the project (Kerzner).

Each of these statements adds to an understanding of what project planning is, but why plan? There are a number of reasons:

The planning process serves as a simulation of the project in the planners' minds before significant resources are expended. Thus false starts are avoided and problems are identified and resolved when solutions are the easiest.
The planning process serves as a means of communication, informing all people on the project what will be expected of them.
Plans identify inconsistency and risk.
Plans provide the basis for action.

Plans must be flexible, and provisions should be provided to update them as needed throughout the project. They should include reasonable contingencies and usually require several iterations before they are acceptable.

Whenever possible, the people who will do the work should plan the work. This develops a sense of ownership of the tasks among those who will actually execute them. Also, having the people most familiar with the work do the planning will usually result in a higher-quality, more realistic plan (Rosenau).

Senior managers tend to apply pressure on the project manager to cut the planning process prematurely short. However, cutting short the planning process is usually false economy. As much as 50% of direct labor hours and dollars can be spent before project execution begins, and companies that spend significantly less usually find quality problems during execution (Kerzner).

Project Planning Steps

The steps in sound project planning are as follows:

Issue project charter.
Develop objectives.
Establish statement of work.
Prepare detailed specifications.
Establish project milestones.
Create the work breakdown structure.
Establish detailed schedules.
Establish detailed budgets.
Define responsibilities.
Replan as required.

Project Charter. The first step in a sound planning process is the issuance of a project charter. A project charter is a formal establishing of the project by the upper management chartering authority (a project is not really a project unless it has management's sanction). As a minimum, the charter should (1) designate the purpose of the project, (2) establish the general organizational format for the project, (3) appoint a project manager, and (4) state management's support for the project.

All projects should be formally launched with some sort of charter. For small in-house projects, it may be only a brief memo. Larger projects will have much more extensive charters. A charter puts the organization on notice that the project is being launched and that it has management's acknowledgment and commitment. The charter is the project manager's action authority to perform the project.

Objectives. Project objectives are the basis for all project planning. Objectives must be clearly stated, specific, measurable, and achievable. They should also be realistic and agreed upon by all parties concerned. Objectives should be consistent with the resources available, and with other organizational plans and projects.

Statement of Work/Specifications. The statement of work (SOW) specifically states what the project will do for the customer. For large projects it will be a formal part of the contract. For projects within the organization it might be a memorandum. The SOW specifies the reason for establishing the project, the desired end results, and the performance, budget, and schedule goals. It may also include specific acceptance criteria, as well as a management section that discusses client relationships, management philosophies, project organization and personnel reporting, contingencies, and communications. The establishment of a satisfactory statement of work may require several iterations. However, it is critical that all parties have a detailed understanding of what is to be done before work proceeds.

Depending on the size of the project, detailed specifications may be listed separately, or included as part of the SOW. They define the standards that must be met with respect to materials, labor, prices, equipment, support, and so forth. It is important to firmly establish detailed specifications up front, as small changes in specifications can have major effects on budgets and schedules.

Project Milestones — Project milestones establish the start and end dates of the project (if known), as well as all the significant subsets. Milestones are designated points in time by which certain specific project tasks/accomplishments are to be completed. The set of milestones forms a group of waypoints that provide a basis for status assessment, management reviews, and replanning the project. Because they are simple to understand, they are an important tool for gauging progress.

Work Breakdown Structure — The work breakdown structure (WBS) is a systematic way of defining the component parts of the project. The WBS breaks down the work to be accomplished into a logical hierarchy of sets, subsets, and so forth so that it is put into "bite-sized" chunks that can be easily understood by planners, schedulers, workers, and managers. More specifically, breaking the project's work into manageable pieces

Facilitates the planning process by describing the total job in terms of discrete tasks.
Allows assignment of these tasks to specific groups and individuals.
Forms the framework on which the budget and schedule are built, since each WBS task can easily be estimated in terms of labor, duration, and other required resources.
Facilitates the chore of scheduling, supervision, and project control and information systems by defining exactly who is responsible for each task and establishing a target completion time.
Simplifies purchasing, scheduling, and staging of required materials.

When creating a WBS, keep the following principles in mind:

Routine or repetitive work should not be excessively subdivided.
Subdivide each block of work to a level that is useful to project management; all blocks do not have to have the same number of subdivisions.
Each task should be easily understood and should have an identifiable schedule.
The cost of the smallest subtask should be significant.

It is essential that a work breakdown structure be created. The WBS forms the skeleton on which the plan, schedule, budget, and control system are built. In addition, a completed WBS is the basis for entering project information into any of the myriad of computerized planning and scheduling systems now being used by virtually all project managers.

Scheduling/Budgeting/Responsibilities/Replanning. The remaining components of project planning — developing a schedule and budget, and assigning responsibilities — naturally follow the creation of the WBS. Once the project's work has been separated into a set of manageable subtasks, it is a straightforward process to set about estimating the time and resources required to complete each one (see the section "Estimating and Contracting"). These estimates are then compiled into a project budget. Similarly, responsibility for each WBS component can be assigned to individuals and groups as appropriate and compatible with available resources. While the scheduling process involves a few more intermediate steps (see the next section), it too is a logical extension of the work breakdown structure. Much of the project plan depends on the WBS. Therefore, project managers should pay close attention to it.

Since plans relate to future events but are based on current knowledge, it follows that plans will need to change during the course of the project. As the project team learns lessons along the way, and as events unfold in the dynamic project environment, project plans will need to be adjusted accordingly. Vehicles for accomplishing this process should be established at the outset. Plans must be kept current. Out-of-date plans hurt project credibility. Besides, the project team needs an accurate roadmap if it is to arrive successfully at its desired destination.

Project Scheduling

Creating a viable schedule and adjusting it as necessary throughout the life of the project is an important part of the project manager's responsibilities.

The scheduling cycle (see Figure 17.7.1) begins with the work breakdown structuring process that subdivides the project's work into a set of manageable and easily understood tasks. The next step is to estimate the time, labor hours, and other resources required to complete each task. Then, the relationships between tasks must be documented. Many tasks can be performed in parallel, whereas some must necessarily come before others. In any case, each task's interdependence with every other task must be determined. The project manager is now ready to create the actual schedule, using one of the methods

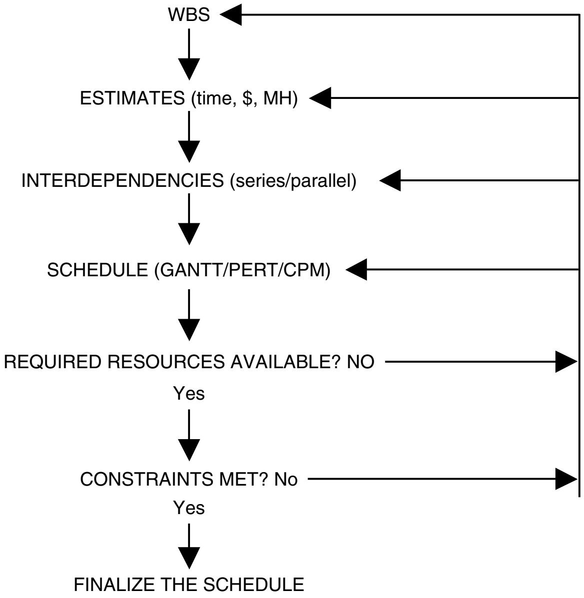

FIGURE 17.7.1 Project scheduling and estimating cycle.

discussed in the next section. Once the schedule is formulated, it must be checked against available resources for feasibility. If the schedule contains periods of time during the project when more resources are called for than will be available, the scheduler must iterate back to an earlier part of the scheduling cycle and make adjustments so that the eventual schedule will prove feasible. Once this is accomplished, the project manager should make a final check to ensure that the proposed schedule will in fact satisfy the project constraints (budget, time, and performance criteria). If constraints are met, the schedule can be finalized.

Scheduling is a continuous process during the life of a project. In the dynamic project environment, changes are always occurring that necessitate replanning and rescheduling. Mechanisms that keep the project plan and schedule valid and current should be put in place at the outset of the project.

Scheduling Methods. The Gantt chart, or bar chart (see Figure 17.7.2), was one of the first techniques used by project managers to schedule and control projects, and it is still widely used. It is simple, graphic, easy to construct and change, and convenient for displaying progress. Project task times are usually shown as horizontal bars that begin and end at the scheduled activity start and end times, respectively. However, Gantt charts do not do a good job of displaying task dependencies and interrelationships. Furthermore, the critical path, the set of sequential activities that define the ultimate length of the project, is not obvious (Rosenau). So, while the Gantt chart is a useful tool for quick overviews and broad statusing of projects, it needs to be augmented by a more comprehensive scheduling tool in all but the most elementary project management situations.

The Critical Path Method (CPM) and Program Evaluation and Review Technique (PERT) are two critical path systems developed to address the shortcomings of the Gantt chart, and enable project managers to do a better job of scheduling complex projects. They both show project task durations, and indicate the earliest task start times as the Gantt chart does, but they also show the *precedence* between activities. This allows the project manager to determine the most critical activities, and more easily modify and determine the status of the schedule.

CPM assumes activity durations are known with a reasonable degree of certainty, and is thus useful in industries like construction that have a long history of performing the various tasks to draw from in formulating accurate project activity estimates (e.g., dig basement, pour footer, etc.) On the other hand,

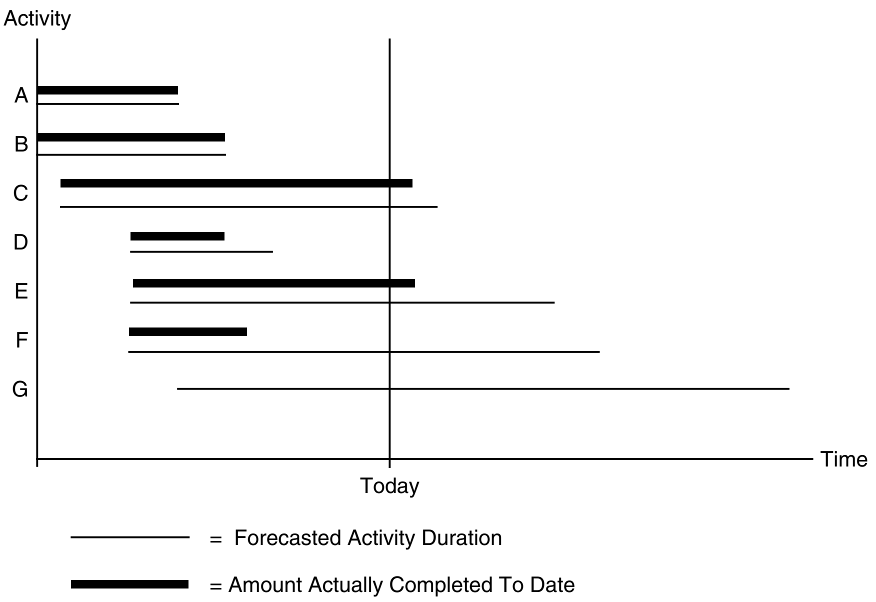

FIGURE 17.7.2 Gantt chart example.

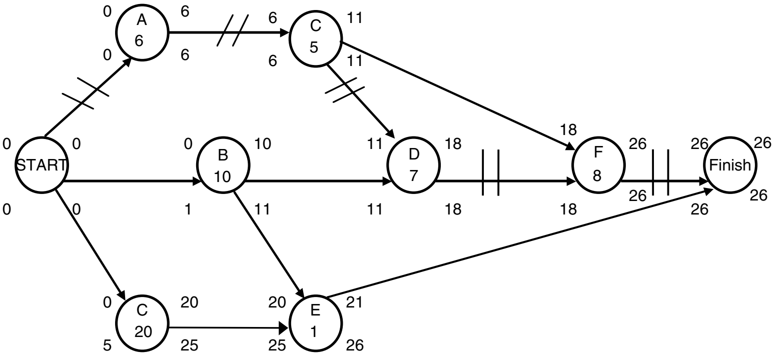
PERT is designed to be used in applications like R&D and aerospace where many activities are being performed for the first time and there is no history to draw on in formulating activity duration estimates. PERT employs statistical techniques to assist the scheduler to devise reasonable activity duration estimates and an estimate for the overall project duration.

Figure 17.7.3 depicts a simple CPM network drawn in the Activity on Node (AON) format. The nodes or circles denote activity. The connecting arrows show precedence between activities. There are various possible routes through the network. The longest route defines the predicted total project duration. The activities on this longest route, or critical path, are called critical activities. Any delay in the execution of these critical activities translates into a delay in overall project completion. Other noncritical activities have a certain amount of leeway (or slack) associated with them that allows the project manager some flexibility in scheduling resources. Thus the project manager should pay special attention to critical activities in making trade-off decisions, as these are the ones that can potentially extend the project duration. However, it should be noted that noncritical activities can potentially become critical if they experience delays greater than their original slack, so the project manager cannot become complacent about noncritical activities either.

In solving the network, forward and backward passes are made according to the formulas given in Figure 17.7.3. Together these two passes determine the earliest and latest starts and finishes for each activity. Also determined are the project's duration, and the critical path (path that contains activities without slack), which represents the predicted project duration. In the example, activities A, C, D, and F have no slack and are thus critical. The path ACDF is the critical path and defines the project duration, 26 days. Once created, the network can be continually updated and used during the life of the project to assist the project manager to understand current project status and make informed trade-off decisions.

It is not feasible to solve any but the simplest PERT/CPM networks by hand. Fortunately, software is widely available for personal computers that is capable of constructing and solving these networks for small and medium-size projects. Very large project networks require the power of larger computers. The Dreger and Suhanic texts (see references) present comprehensive information about using computers in project management. A more detailed exposition of PERT/CPM techniques can be found in the Moder, Phillips, Davis text (see references).



KEY

ES **EF**

RF **LF**

ID = Activity ID

t = Activity Duration

LEGEND

ES = Earliest Activity Start

EF = Earliest Activity Finish

LS = Latest Allowable Activity Start

LF = Latest Allowable Activity Finish

Forward Pass

ES = Max(preceding EF's)

EF = ES + (activity duration)

Backward Pass

LF = Min(succeeding LS's)

LF = LF – (activity duration)

Non-critical Activity Slack = LF – EF = LS – ES

CRITICAL PATH = ACDF = 26 DAYS PROJECT DURATION – ⫽

NON-CRITICAL ACTIVITIES: B (slack = 1 day)

C (slack = 5 days)

E (slack = 5 days)

Staffing and Organizing

In staffing and organizing a project, management must bring together a diverse group of people, equipment, information, and other resources that, when properly integrated, is capable of achieving the project objectives. Each element of the resulting system is critical to overall project success.

Selecting the Project Manager. The project manager is the most critical selection. A person should be selected who:

Serves full time on the project. With few exceptions, appointing a part-time project manager is not practical for projects of any significance. Naming a part-time project manager signals the organization that the project is a low priority. This practice is not fair to the individual or to the project, and usually produces less-than-optimum results.

Has a proven track record. Most project situations are poor training grounds for project managers with little or no experience or training. A project manager's credibility with the organization is vital.

Functions as a manager, not a doer. If the project manager spends all of his or her time performing technical tasks, then, in effect, there is no project manager. With no one in the driver's seat, budgets, schedules, customer relations, and other critical project management components are left unattended.

Possesses good interpersonal skills. A project manager may be called upon at any time to be a communicator, mediator, negotiator, motivator, coach, counselor, and leader.

Project Team Staffing. The project manager may have little or no control over the composition of the project team, as the functional managers of the contributing departments are often the ones who decide which individuals serve on the project. Hence, project managers must be able to mold a potentially broad mix of talents, functional backgrounds, and professional experience into an integrated team. This is one reason why team-building skills are vitally important. (See the section "Team Building.") Given a choice, the project manager would opt for project team members who are assigned full-time to the project, experienced in project work and their discipline, and team players, and who relate well with customer representatives when direct interchange is required.

Organizing for Project Management. Projects are conducted under an infinite variety of organizational structures. Project managers usually have little input in this area and must learn to make the best of the organizational structure in which they find their project operating. However, project managers should bear in mind that, while organizational structures may serve either to facilitate or impede project progress, they are usually not a principal factor in determining overall project success or failure. Other factors, like thorough planning and building a cohesive, motivated project team, are more predictive of project success. Besides, as Kerzner so aptly points out, any organizational form will work if the people want it to.

Nevertheless, project managers should be cognizant of the strengths and weaknesses of the organizational structure under which they are operating so they can make the best of their situation. Table 17.7.1

TABLE 17.7.1 Advantages and Disadvantages of the Three Main Organizational Forms from a Project Management Perspective

Organizational Structure	Advantages	Disadvantages
Functional/Hierarchical/ Classical	• Close control of budget and people • Well-defined authority and communications channels • Well-understood career paths • Best for mass production • Nurtures functional areas; assures up-to-date technology. • Provides security for individuals (in functional groups)	• No one person truly in charge of the entire project • Long lead times, ineffective integration, very slow internal communications • Ineffective communications with the customer • Difficult to know status of projects • Very slow to respond to change • Strongest functional group tends to dominate decision making • Poor conflict resolution, great reliance on hierarchical referral • Tendency to suboptimize
Pure Project/product/ Divisional	• One individual in authority to speak for the project • Quick response to changing environment • Personnel allocated completely to the project • Good communications • Less need for hierarchical referral to resolve conflict • Most likely to complete the project on time	• Less efficient use of resources • Does not nurture functional disciplines • Best when company is project-oriented • Uncertainty for personnel when project ends (where do they go?)
Matrix	• More efficient: project can share personnel and more easily accommodate changing requirements • Good communications • Personnel security (people have homes to go to after project is finished) • Technical disciplines are supported/nurtured • Quick to respond to change • One person speaks for the project	• High potential for conflict • Project personnel must work for two bosses • Heavy penalty in communications requirements and other administrative overhead costs • Best for project-oriented organization • Competition for best resources • Upper management may see matrix as requiring them to give up some authority

TABLE 17.7.2 Six Key Team Building Elements

1. **In all actions, demonstrate respect and consideration for all employees as valued members of the team.** Are employees encouraged by example and admonition to respect each other? Do they know enough about each other's job to appreciate the contributions others are making? Does a general atmosphere of consideration exist?
2. **Identify individual job responsibilities and performance standards and see that they are known.** Are individual discussions held to ensure that each employee knows his or her job's standards and responsibilities? Does each team member understand how his or her portion of the project is important to overall project success?
3. **Work to secure good communications with employees as individuals and as a team.** Do team members feel their inputs and suggestions are valued? Do they receive regular feedback on how they are doing? Is advance warning of changes conveyed whenever possible along with reasons why changes are necessary? Are regular exchange meetings held? Are team members included in decision making?
4. **Establish individual and group goals, preferably in coordination with those concerned.** Are individual goals established for each team member? Is consideration given to each individual's opportunities for professional development? Are group goals established and communicated to the team? Is a goal established that encourages growth in team development factors like team planning, conflict resolution, and problem solving?
5. **Reward teamwork and team building efforts.** Who issues rewards? Project managers? Functional managers? Are rewards mostly based on extrinsic job factors like pay, bonuses, and working conditions, or are they based on intrinsic job factors like accomplishment, recognition, responsibility, and growth? Does management recognize the difference between rewarding an individual as a member of a team, and rewarding an individual as an individual? Are individuals singled out and rewarded for their performance on the project team? Do team members have input into what and how rewards are given and to whom?
6. **Practice and encourage loyalty to the team.** Does the project manager defend team members against unfair criticism? Is there a climate of trust on the project team? Do project managers practice effective leadership?

gives some of the advantages and disadvantages of the three principal organizational structures and their many variants, from a project management perspective.

Regardless of the organizational form used, it is a good idea to create a steering team to oversee and guide important projects. A steering team of senior managers demonstrates management support of the project, helps with integration and hard problems, provides oversight and guidance, makes major dollar decisions, and acts as an interface with upper management.

Team Building

Today's projects characteristically require the efforts of many people from multiple disciplines whose efforts must be effectively integrated to meet project objectives. Further, project managers must cope with dynamic environments, high degrees of organizational complexity, and ever-increasing competitive pressures. Experienced project managers know that the only way to effectively deal with these challenges is to mold their project personnel into true project *teams,* or groups of people with complementary skills who are committed to a common purpose, set of performance goals, and approach for which they hold themselves mutually accountable (Katzenbach and Smith). Teams feature enhanced efficiency, increased motivation, self-regulation, synergistic output, flexibility, and heightened confidence (Raudsepp), all of which are vital to project success in the present competitive environment. Thus, team building is an essential project management skill.

Robert P. Hagen has advanced six key elements of most successful team-building plans which, if implemented by project managers, would greatly enhance the state of team building on project teams (Table 17.7.2).

Project Control

Planning puts the team in a position to launch a project. However, rarely does everything go according to plan. As soon as the project begins, deviations start to occur. Thus, once the project is launched, controlling to the plan becomes a principal function of project management.

It is up to the project control system to keep the project manager apprised of how all components of the project are progressing, and highlight significant problems and deviations from plan so that corrective action can be taken. Without a control system, the project manager has little influence over the project, and it will meander to completion in some form or fashion.

An effective project control system combines a cost accounting function and a cost control function with appropriate mechanisms for monitoring progress against schedule and technical performance targets. The cost accounting function accumulates actual costs, ensures costs are properly allocated, and verifies work is carried out and billed correctly. The cost control function provides the information to support cost analysis, prediction, and reporting. Costs are maintained within budget by taking corrective action wherever predicted costs exceed the budget.

Among the most critical requirements of a project control system is providing a capability to compare budgeted costs to actual costs and then conducting variance analyses that lead to corrective action. The earned value approach to variance analysis is widely used. It compares the budgeted cost of work performed (BCWP), or earned value, with the actual cost of work performed (ACWP) to determine the cost variance (CV). It compares the BCWP with the budgeted cost of work scheduled (BCWS), or planned earned value, to determine the schedule variance (SV).

ACWP and BCWS are fairly straightforward to obtain. On the other hand, it may be difficult to obtain an accurate representation of BCWP. One approach is to use standard dollar expenditures for the project so that x% of the costs are booked for x% of the time. Another is the 50/50 rule, in which half the budget is recorded when an activity is scheduled to begin and the other half when the activity is scheduled to complete. Other alternative approaches may depend on percentage of labor hours expended, parts installed, programs written/tested, and other factors. There are many other possible approaches; however, the object is to somehow measure the percentage complete for project activities (or *earned value*). On some projects the time, trouble, and expense to obtain an accurate BCWP may not be cost effective.

Figure 17.7.4 gives a graphical presentation of the earned value approach and summarizes some quantitative indices useful to project managers conducting variance analysis. Once identified, each critical variance must be investigated to determine the cause and the appropriate corrective action.

Such an investigation should begin at the lowest organizational level by the supervisor involved. It then progresses upward to the project manager who reviews variance causes and approves corrective actions. Normally the project manager will review these results with upper-level management prior to preparing the contractually required reports to the customer.

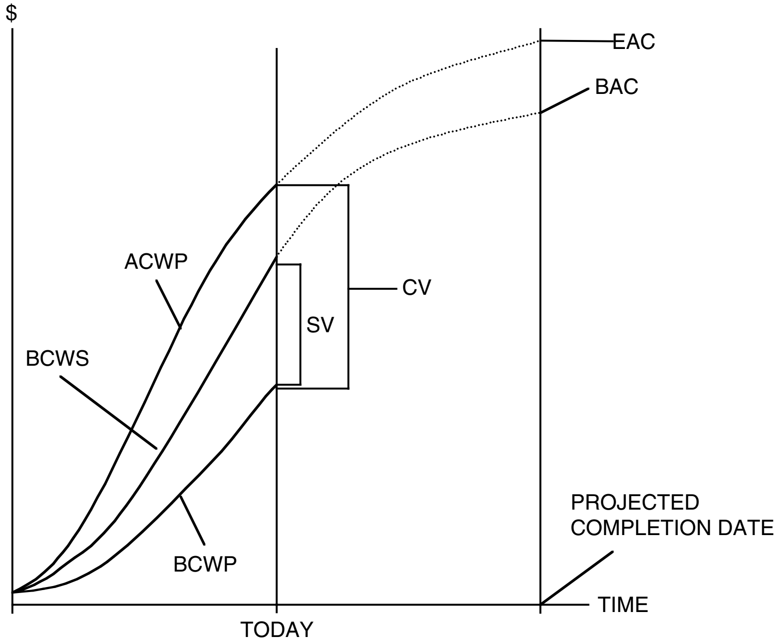
Estimating and Contracting

Project Estimating. Estimating time and resource requirements on projects is frustrating because the project manager knows in advance that the probability of being exactly correct is slim. The key, then, is to not be afraid to be wrong, but rather simply strive to be as accurate as possible, given what is known at the time.

A simple three-step approach will serve as a starting point for estimating:

1. Top-Down Estimate — Make an initial estimate at an overview level…an order of magnitude estimate using the broad, big picture view.
2. Detailed Bottom-Up Estimate — Follow the top-down estimate with a detailed estimate built from the bottom up. Start with the lowest tasks in the work breakdown structure and work up by task, by department, and so on, arriving at a total figure.
3. Comparison — Compare the two estimates.

In effect, each estimate provides a reality check for the other. If the two are in relative agreement, it is likely that a good estimate has been developed. However, if the two figures are very different, more analysis is indicated. Go back and examine the individual work packages to discover where costs may differ, and to what extent there have been incorrect assumptions made as to the scope and content of work called for. Once the areas of principal differences between the two estimates have been determined, decisions can be taken as to which is correct.



BCWP = BUDGETED COST OF WORK PERFORMED = EARNED VALUE
BCWS = BUDGETED COST OF WORK SCHEDULED = PLANNED EARNED VALUE
ACWP = ACTUAL COST OF WORK PERFORMED
CV = COST VARIANCE = BCWP – ACWP
SV = SCHEDULE VARIANCE = BCWP – BCWS
CV% = COST VARIANCE PERCENTAGE = CV/BCWP
SV% = SCHEDULE VARIANCE PERCENTAGE = SV/BCWS
EAC = ESTIMATE AT COMPLETION = (ACWP/BCWP) = (TOTAL BUDGET)
(NEGATIVE IS UNFAVORABLE)

FIGURE 17.7.4 Graphical earned value presentation.

Contingency planning is an important part of estimating. It is usually not appropriate to place a blanket contingency figure (e.g., 10%) across all tasks. Rather, contingency budgets should be set deliberately, considering each activity individually and being careful not to build contingency on top of contingency.

In developing detailed estimates, time and dollars to cope with the following issues should not be overlooked (Rosenau):

Interfacing with customers, upper management, and other departments
Obtaining customer furnished items
Getting approvals
Working at remote/difficult locations
Training people
Making mistakes
Obtaining security clearances
Placing major subcontracts and purchase orders
Replacing sick and vacationing people

Contracts. There are many types of contractual agreements used on projects. However, most can be categorized as variations on two basic types of contracts: fixed-price and cost-reimbursable. Under a fixed-price contract the customer agrees to pay a specific amount upon satisfactory completion of the project. A cost-reimbursable contract is one in which the customer agrees to reimburse the contractor organization for costs actually incurred in performing the project.

The fixed-price contract presents the lowest financial risk to the customer because the maximum financial liability is specified. This form presents the highest risk to the contractor organization, although it also opens the door for increased profits if the contracted costs can be underrun. On the other hand, under a cost-reimbursable contract, the customer is obligated to reimburse the contractor for all costs incurred, and thus bears considerable risk. The usual arrangement under cost-reimbursable contracts is to add a fixed fee or an incentive fee to the costs to arrive at the total compensation figure due the contractor. Cost-reimbursable contracts are traditionally used when the nature of the project dictates that accurate pricing cannot be determined.

Market conditions also influence the type of contract used. When work is scarce, customer organizations often insist upon fixed price contracts. Conversely, when business is good, customers are not able to insist upon fixed-price contracts, and more cost-reimbursable type contracts are used.

Summary

Project management is among the most challenging undertakings in the field of management today. Project managers routinely face formidable performance requirements, firm budget constraints, and tight schedules. They must organize people from diverse technical backgrounds into a cohesive, motivated team, and then lead that team as it plans and executes its complex tasks in an ever-changing environment.

While the most successful technical people are often promoted to project management, it takes more than a solid technical background to make an effective project manager. To qualify an individual for project management, sound training in the fundamentals is essential, along with on-the-job experience as a project team member and/or assistant project manager or project engineer.

Those characteristics constitute but the tip of the iceberg in terms of required knowledge for project managers, but will perhaps give the uninitiated a starting point. The excellent references we have listed will serve to fill in many of the gaps for the interested reader.

Defining Terms

Activity on Node (AON): A scheduling network in which the circles (or nodes) represent activities, while the connecting lines denote the sequence the activities must follow (see Figure 17.7.3).

Actual cost of work performed (ACWP): Actual dollars expended on a given project activity.

Budgeted cost of work performed (BCWP): Earned value of completed work.

Budgeted cost of work scheduled (BCWS): Planned earned value.

Gantt chart: The Gantt chart, named after Henry L. Gantt, is a bar chart useful in project management to depict planned and actual progress of project activities on a horizontal time scale (see Figure 17.7.2).

Network: A combination of arcs and nodes linked together to represent project activity durations and precedences. Used in conjunction with a solution technique like CPM or PERT, estimates of project completion times, critical activities, and resource requirements can be determined.

PERT/CPM: PERT stands for Program Evaluation and Review Technique, while CPM stands for Critical Path Method. Both are methods for solving a project activity network. CPM is used on projects where activity time estimates are well established, like on construction jobs. PERT is used on projects where times to complete activities are not known with a great deal of certainty, such as in aerospace and R&D applications. Almost always used in conjunction with computer software, these techniques yield estimates of overall project completion times, listings of the most critical activities, and resource requirements by time frame.

Statement of work (SOW): Formal statement delineating specifically what the project will do for the customer. As a minimum it should contain performance, budget, and schedule objectives.

Work breakdown structure (WBS): A logical division of the work involved in the project into a hierarchy of component parts. It forms the basis for subsequent project budgeting, scheduling, and controlling.

Nanotechnology[*]

Sergey Edward Lyshevski
Rochester Institute of Technology

This chapter emphasizes the far-reaching problems in synthesis, design, analysis, modeling, simulation, and simulation of nanomachines. Rotational and translational nanomachines, controlled by nanoscale integrated circuits, can be widely used as nanoscale actuators and sensors. Although this is still a vision that may not materialize in near future, say within 20 to 30 years, fundamental and applied research should be performed. The implications of nanotechnology to motion nanodevices have received meticulous consideration as technologies to fabricate these nanomachines have been studied and developed. Furthermore, basic fundamentals and applied researched have been performed. Organic and inorganic micromachines (fabricated using micromachining technologies) serve as nanomachine prototypes and proof-of-concept paradigm. These micromachines have been tested and characterized. One must address and solve a spectrum of problems in synthesis, analysis, modeling, optimization, biomimicking, and prototyping of nanomachines. These nanomachines and motion nanodevices must be synthesized (devised) before attempts to analyze, optimize, and fabricate them, because basic physical features, energy conversion, operating principles, and other issues significantly contribute to sequential tasks in analysis, control, optimization, and design. This is of particular significance for electromagnetic and chemo-electromagnetic motion nanomachines. This chapter reports and successfully applies distinct concepts

and methods. In particular, the field of engineering biomimetics is applied to prototype nanomachines, and the synthesis and classification solver that allows one to synthesize novel nanomachines, as well as classify and refine various motion nanodevices, is discussed. The fundamental, applied, and experimental results are documented in order to accomplish the analysis and design illustrating their significance, validity, and effectiveness.

18.1 Introduction

The benchmarking problems in the synthesis of nanomachines have challenged scientists for a long period of time. All synthesized nano- and microscale machines and motion devices benefit from mimicking of biomachines. Due to nanobiomachines complexity, it is yet unknown how these motion nanobiodevices operate. The basic physics of different electromagnetic-based nanomachines must be examined because nanobiomachines operate based on chemo-electromagnetic phenomena. Distinct feasible electromagnetic nanomachines are reported in this chapter.

Nanomachines and motion nanodevices should be modeled, simulated, and analyzed. We examine the questions of viability of the devised nanomachines studying *Escherichia coli* (*E. coli*) nanobiomotor, magnetotactic bacteria, and so forth. The goal is to further expand nanotechnology and nanosystems horizon by devising new nanomachines and motion nanodevices solving sequential synthesis, modeling, simulation, analysis, and optimization problems. To attain the highest degree of integrity, high-fidelity models are developed and examined. A wide spectrum of interactive software tools, algorithms, and programs have been developed to solve these long-standing problems in heterogeneous simulation and data-intensive analysis. The optimization and control problems should be solved to guarantee the superior overall performance of nanomachines. Using the developed mathematical models, the simulation results illustrate the efficiency of the modeling, analysis, and optimization methods.

18.2 Applications of Engineering Biomimetics in Nanomachines Prototyping

One of the most challenging problems in nanomachine synthesis and prototyping involves the basic physics understanding, analysis, synthesis, and optimization. The synergetic attempts to prototype and design nanomachines have been pursued through analysis of complex patterns and paradigms of evolutionary developed nanobiomachines, for example, *Escherichia coli*, *Salmonella typhimurium*, and others.[1–4] Although promising results have been reported, the basic physics of nanobiomachines is barely comprehended and virtually unknown.[2] At the same time, distinct nanomachines have been devised postulating different electromagnetic fundamentals.[3,4] For example, it is possible that the physics of some nanomachines is based on magnetic media, variable reluctance, or induction electromagnetics. The analysis of the *E. coli* and *Salmonella typhimurium* rotor structures indicates that nanobiowindings can exist. The voltages supplied to these nanowindings can be controlled (regulated) by the nanobiocircuits formed by the proteins that may form nanobioprocessors. As a result, we study different electromagnetic-based nanomachines.

Consider the nanobiomotor of *E. coli* bacteria. The flagella (rotated by nanobiomotors) are used for propulsion. The bacterium is propelled with a maximum speed of 20 μm/sec by flagellar filaments. This filament is driven by a 45 nm rotor of the nanobiomotor embedded in the cell wall. The cytoplasmic membrane forms a stator. This nanobiomotor integrates more than 20 proteins and operates as a result of to the axial *protonomotive* force resulting due to the proton flux. The rated nanobiomotor parameters were found to be as follows:[2]

- Angular velocity is 20 rad/sec.
- Torque is 1×10^{-16} N-m.
- Efficiency is 50% (estimated).

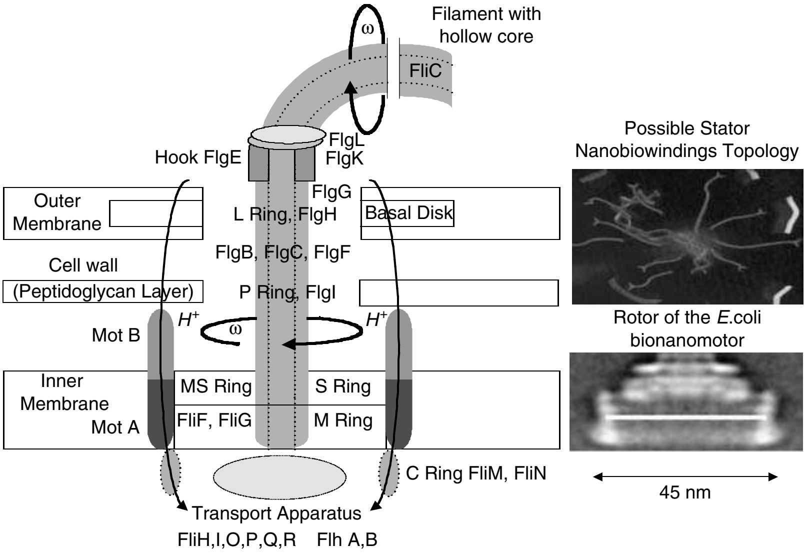

FIGURE 18.2.1 *E. coli* nanobiomotor: integrated nanobiomotor-coupling-flagella complex with different proteins and rings, rotor image, and possible protein-based bionanocircuitry geometry.

It was commonly reported that the *E. coli* nanobiomotor has three *switch* proteins (FliG, FliM, and FliN) that control the torque, angular velocity, and direction of rotation, respectively.[2] These proteins are involved in the flagellar assembly. The flagellum, flexible joint, and nanobiomotor are shown in Figure 18.2.1.[2-4] The nanobiomotor has two major parts: a *stator* (connected to the cell wall) and a *rotor* (connected to the flagellar filament through a flexible joint).

Consider nanobiomotor assembly using common terminology. The stator is built using the so-called MotA and MotB complexes, while the rotor is built by FliF, FliG, FliM, and FliN proteins forming the so-called MS and C rings. The shaft is made from the proteins FlgB, FlgC, FlgF, and FlgG, whereas the bearing is built from the proteins FlgH and FlgI forming the so-called L and P rings. The MS, P, and L rings each contain many copies of FliF, FlgI, and FlgH proteins, respectively. Reference 2 reports that there are eight stator elements (MotA and MotB complexes), each of which exerts the same force. The torque is developed due to axial flux of protons (in marine bacteria and bacteria that live at high pH, the sodium ions establish the axial flux). The source of energy is a transmembrane electrical potential and/or pH gradient. Thus, the *E. coli* nanobiomotor is a chemo-electromagnetic nanobiomachine.

MotA and MotB complexes form a transmembrane channel. According to reference 2, proton translocation may cause the cytoplasmic part of MotA to move or change the geometry, producing the force on FliG. The motor rotates clockwise and counterclockwise, changing the direction as a result of the command signals. When the nanobiomotor rotates clockwise, the flagellar filaments work independently, and the cell body moves erratically with little net displacement (bacterium tumbles). When the nanobiomotor rotates counterclockwise, the filaments rotate in parallel in a bundle that propels the cell body forward (bacterium runs). Although the direction of rotation and some nanobiomotor data can be evaluated, the basic physics of nanobiomachines and their components (proteins) is virtually unknown.[2]

Some bacteria have organic and inorganic magnetic media. In 1962 Professor Lowenstam discovered magnetite (Fe_3O_4) biomineralization in the teeth of chitons, demonstrating that living organisms were able to precipitate the mineral magnetite. In 1975 Richard Blakemore discovered the magnetotactic bacteria. It was found that distinct magnetotactic bacteria contain magnetosomes (magnetic mineral particles) enclosed in the protein-based membranes. In most cases the magnetosomes are arranged in a chain or chains fixed within the cell. In many magnetotactic bacteria, the magnetosome mineral particles are ether 30 to 100 nm magnetite (Fe_3O_4) or, in marine and sulfidic environments, greigite (Fe_3S_4). These

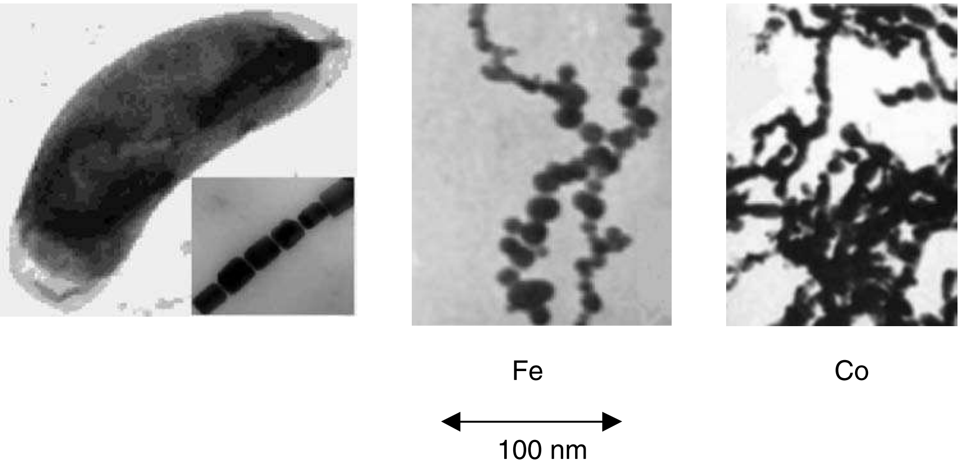

FIGURE 18.2.2 Magnetotactic bacterium and image of a chain of 60–100 nm diameter cylindrical magnetosome mineral magnetic particles. Nanobabricated Fe and Co nanoparticles and their nanoassemblies.

nanoscale permanent magnets sense the magnetic field, and bacteria swim (migrate) along the magnetic field lines. Whether the magnetic mineral particles are magnetite or greigite, the chain of magnetosome particles constitutes a permanent magnetic dipole fixed within the bacterium. Correspondingly, magnetotactic bacteria have two magnetic poles depending on the orientation of the magnetic dipole within the cell. The poles can remagnetized by a magnetic pulse that is greater than the coercive force of the chain of particles. The magnetosome particles that are almost perfectly uniformly magnetized form permanent magnetic domains. All particles are arranged along the chain axis such that the crystallographic magnetic easy axes are also aligned. The size specificity and crystallographic orientation of the chain assembly is optimally designed for magnetotaxis in the geomagnetic field. Magnetosome particles occur in at least three different crystal forms. In *M. magnetotacticum*, cubo-octahedral forms (cubic crystal symmetry of magnetite) is observed. A second type, found in coccoid and vibrioid strains, is an elongated hexagonal prism with the axis of elongation parallel to the 111 crystal direction. A third type, observed in some uncultured cells, is an elongated cubo-octahedral form producing cylindrical, bullet-shaped, teardrop and arrowhead particles, as Figure 18.2.2 shows.

Examining nanomachines and motion nanodevices that can be fabricated using nanotechnology, it is important that these magnetic materials and magnetic nanoassemblies can be created in a straightforward manner. The iron oxide (Fe_3O_4) can be affordably fabricated with 99% purity, and the size of particles is from 15 to 30 nm (the morphology is spherical and the density is 5 g/cm^3). High-energy density nanomagnets can be made. Figure 18.2.2 illustrates the nanotechnology-based fabricated Fe (99% purity, 25 nm size, and 8 g/cm^3 density) and Co (99.8% purity, 27 nm size, and 9 g/cm^3 density) nanoparticles and their assemblies that can be used in electromagnetic (and electrostatic) nanomachines and motion nanodevices. These Fe and Co nanoparticles can be magnetized, making the nanomagnet arrays for nanomachines.

18.3 Nanomachines Synthesis and Classification

The field of engineering biomimetics addresses fundamental design issues that are common to all nanomachines and provides valuable insight in prototyping, synthesis, and design of nanomachines and motion devices. Using recently developed basic results and performing fundamental research,[3,4] researchers have shown that nanobiomachines can operate due to the reluctance difference in the *closed protonomotive* system, interaction of magnetic fields established by nanowindings and magnetic media, induction electromagnetics, and so forth. Nanomachine performance depends on nanomachine operating principle,

TABLE 18.3.1 Nanomachines Synthesis and Classifier

	Open Ended (Open), O						Σ
	Integrated, I	Σ	Σ	Σ	Σ	Σ	Σ

topology, materials, and other factors. Novel nanomachines should be synthesized, and cornerstone synthesis paradigms must be derived. It is evident that electromagnetic systems and geometry can be applied as the basic variables of particular importance. Different synthesis and classification paradigms were developed in References 3–5.

A *nanomachine synthesis and classification solver* is described and demonstrated in Table 18.3.1.[3,4] This solver, which allows one to synthesize and classify electromagnetic-based motion nanodevices, is partitioned into 3 horizontal and 6 vertical strips, and contains 18 sections, each identified by ordered pairs of characters, for example, (*E*, *P*) or (*O*, *C*). Hence, the electromagnetic system–geometric set is given as

$$M \times G = \{(E,F),(E,S),(E,T),\cdots,(I,N),(I,C),(I,A)\},$$

and, in general, we have $M \times G = \{(m,g): m \in M \text{ and } g \in G\}$.

The electromagnetic *synthesis and classification* solver represents nanomachines and nanodevices as

$$M \times G = \{(m,g): m \in M \text{ and } g \in G\},\quad M \times G = \{(E,F),(E,S),(E,T),\cdots,(I,N),(I,C),(I,A)\}$$

Here, the first entry is a letter chosen from the bounded electromagnetic system set, where *E*, *O*, and *I* are the *endless*, *open-ended*, and *integrated* electromagnetic systems, respectively; hence, *M* = {*E*, *O*, *I*}.

The second entry is a letter from the geometric set, where the geometries are denoted as plate (P), spherical (S), torroidal (T), conical (N), cylindrical (C), and asymmetrical (A) geometry, that is, $G = \{P, S, T, N, C, A\}$.

It must be emphasized that the synthesis and classification solver allows one to attain the topological synthesis. For example, radial and axial topology nanomachines result. Using the possible geometry and electromagnetic (chemo-electromagnetic or opto-electromagnetic) systems (*endless*, *open-ended*, and *integrated*), novel organic, inorganic, and hybrid nanoactuators can be synthesized. Different distinct features (induction and synchronous electromagnetics, magnets and ferromagnetic core geometry, magnetization characteristics, *emf* distribution, power, torque, size, packaging, etc.) result. Then, performing modeling, simulation, and analysis, the designer optimizes nanomachine performance. One of the most critical problems is to develop accurate mathematical models that allow the designer to perform data-intensive analysis and heterogeneous simulations in order to guarantee accurate performance predictions.

The analysis of nanobiomachines is far from complete, and there is a significant lack of reliable data.[1–4] There are some possible torque production and energy conversion mechanisms that lead to the corresponding operation of electromagnetic-based nanomachines and motion nanodevices:

1. Synchronous electromagnetics: The torque results due to the interaction of a time-varying magnetic field established by the stator (rotor) windings and a stationary magnetic field established by the rotor (stator) permanent nanomagnets or nanomagnet arrays.
2. Induction electromagnetics: The rotor currents are induced in the rotor windings due to the time-varying stator magnetic field and motion of the rotor with respect to the stator; the torque results due to the interaction of time-varying electromagnetic fields.
3. Variable reluctance electromagnetics (synchronous nanomachine): The torque is produced to minimize the reluctance of the electromagnetic system; for example, the torque is developed by the magnetic system in an attempt to align the minimum-reluctance path of the rotor with the time-varying rotating air gap *mmf*.

18.4 Synthesis, Design and Analysis of Nanomachines

Different nano- and microscale machines and motion devices have been devised and studied in References 3 and 4. In general, the rotational and translational nanomachines can be classified as synchronous and induction. A step-by-step procedure in the nanomachine synthesis and design is as follows:

1. Devise (synthesis, prototyping and classification tasks) nanomachine researching operational principles, topologies, configurations, geometry, electromagnetic systems, and other features.
2. Study electro-chemo-mechanical energy conversion and sensing-feedback-control mechanisms (phenomena).
3. Define application and environmental requirements with performance specifications.
4. Perform electromagnetic, energy conversion, mechanical, vibroacoustic, and sizing/dimension (stator, rotor, nanomagnets, air gap, winding, etc.) estimates.
5. Define (affordable and high-yield) technologies, processes, and materials to fabricate structures (stator, rotor, bearing, post, shaft, etc.) and assembly of nanomachines.
6. Perform coherent electromagnetic, mechanical, vibroacoustic, and thermodynamic design with performance analysis synergetically assessing synthesis, design, and optimization.
7. Modify, refine, and optimize the design.

Thus, in addition to devising nanomachines and motion nanodevices, they should be coherently examined. It is important to accurately model, simulate, and analyze very complex electromagnetic, electromechanical, and vibroacoustic phenomena in motion nanodevices in order to optimize the design. For example, the ultimate goals can be

- Increase efficiency, reliability, robustness, ruggedness, and survivability.
- Maximize the power, torque, and force densities.
- Minimize and attenuate vibrations and noise.
- Minimize losses and torque ripple.

In this way, affordable high-yield fabrication can be achieved. The nanomachine topologies significantly influence nanodevice performance and fabrication. Many of the problems listed have not been addressed and solved yet. To meet our objectives, one must study complex phenomena and perform optimization with ultimate objectives to guarantee superior *achievable* performance (efficiency, robustness, power density, etc.). To attain the desired nanomachines integrity, we must depart from the conventional concepts. We introduce entirely new paradigms that are based on

1. Engineering biomimetics (to prototype nanomachines)
2. The synthesis and classification solver (to synthesize and classify nanomachines)
3. Electromagnetic-mechanical optimal design (to maximize efficiency, robustness, power density, etc.)

To attain our objectives, mathematical models are developed as nanomachines are synthesized. In order to ensure superior *achievable* performance, these nanomachines must be designed for high electromagnetic loads, electromagnetic field and flux (current) densities integrating saturation, hysteresis, and high-frequency harmonics effects. Therefore, the electromagnetic and electromechanical mechanisms must be examined. Hence, the major emphases should be focused on the development and validation of robust and affordable concepts that guarantee significant advantages, for example, increase of efficiency, robustness, reliability, torque density, and expanded operating envelope.

18.5 Synchronous Reluctance Nanomachines

Prototyping and Synthesis of Synchronous Reluctance Nanomachines

The protein folding changes the permeability of the media. This can result in the variable reluctance of the *E. coli* rotor (the MS ring that consists of FliF and FliG proteins) as rotor rotates. At the same time, the *E. coli* nanobiomotor can operate as a synchronous reluctance nanomachine, as shown in Figure 18.5.1.

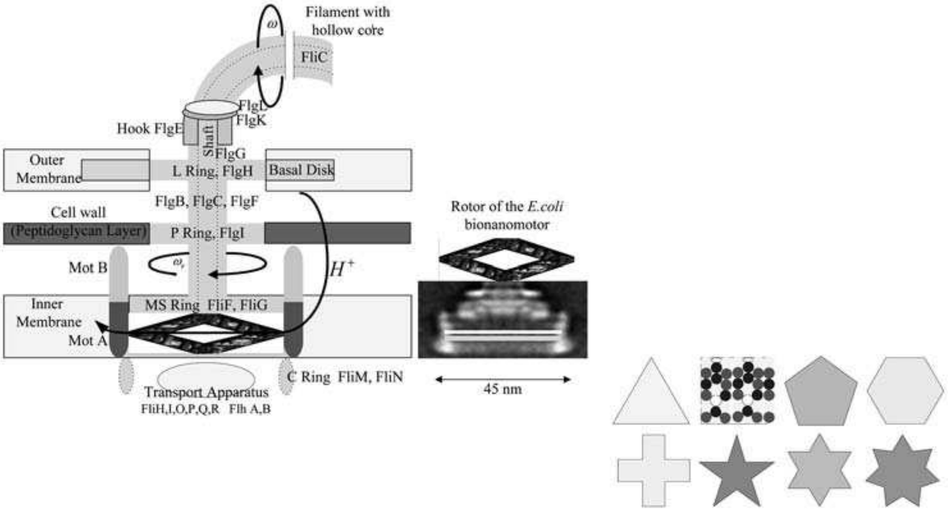

FIGURE 18.5.1 *E. coli* nanobiomotor with a possible rotor protein assembly.

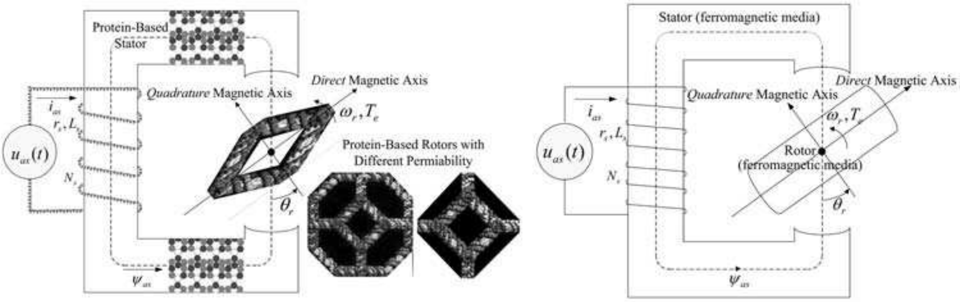

FIGURE 18.5.2 Single-phase reluctance nanomachine and the proposed nanomotor with variable reluctance rotor.

One can hypothesize that there is a possible reluctance difference in the *closed protonomotive* system in the *E. coli* nanobiomotor. Correspondingly, the torque is developed due to change of reluctances as rotor rotates. To illustrate the concept, consider the nanoactuator prototype synthesized using three-dimensional molecular assemblies. For example, the engineered[6] triangle, square, pentagon, heptagon, truncated octahedron, cross, star $N_{5,6,7,\ldots}$, and other geometry of protein assemblies shown in Figure 18.5.1 results in different reluctances due to the distinct length of the protonomotive flux through the media (protein) as rotor rotates. Hence, the reluctance of the magnetic path varies as the rotor rotates as a function of the rotor angular displacement θ_r. This leads one to synthesis of the synchronous reluctance nanomachines. In particular, instead of in the *closed protonomotive* system in the *E. coli* nanobiomotor, we design a nanomachine with the *endless* (*closed*) electromagnetic system that has a different reluctances as the rotor rotates. To illustrate the paradigm, a single-phase reluctance nanoactuator is documented in Figure 18.5.2. This nanomachine can be fabricated as a nanoactuator, shown in Figure 18.5.2.

Modeling, Analysis, and Design of Synchronous Reluctance Nanomachines

Having performed synthesis (and classification) of synchronous reluctance nanomachines, we must now model, simulate, analyze, and optimize those nanomachines. To fulfill our objectives, the augmented mathematical model for the studied single-phase nanomotor is developed as[3]

1. circuitry equation (Kirchhoff's law) is $u_{as} = r_s i_{as} + \dfrac{d\psi_{as}}{dt}$.
2. *tensional-mechanical* equation (Newton's law) is $T_e - B_m\omega_r - T_L = J\dfrac{d^2\theta_r}{dt^2}$.

Here, the nanomachine variables are the phase voltage, current and flux linkages denoted as u_{as}, i_{as} and ψ_{as}; the angular velocity and angular displacement denoted as ω_r and θ_r; and the electromagnetic and load torques denoted as T_e and T_L.

The synchronous reluctance nanomachine parameters are the armature resistance r_s, the moment of inertia J, and the friction coefficient B_m.

As illustrated in Figure 18.5.2, the *quadrature* and *direct* magnetic axes are fixed with the rotor. The rotor rotates with angular velocity ω_r. The magnetizing reluctance $\Re_m$ is a function of the rotor angular displacement θ_r. Using the number of turns N_s, the magnetizing inductance is found to be $L_m(\theta_r) = N_s^2\Re_m^{-1}(\theta_r)$. This magnetizing inductance varies twice per one revolution of the rotor and has minimum and maximum values. In particular, one has $L_{m\min} = N_s^2\Re_{m\max}^{-1}(\theta_r)\Big|_{\theta_r=0,\pi,2\pi,\ldots}$ and $L_{m\max} = N_s^2\Re_{m\min}^{-1}(\theta_r)\Big|_{\theta_r=\frac{1}{2}\pi,\frac{3}{2}\pi,\frac{5}{2}\pi,\ldots}$ The inductance changes as a sinusoidal function of the rotor angular displacement as reported in Figure 18.5.3. Hence, one has $L_m(\theta_r) = \bar{L}_m - L_{\Delta m}f(\theta_r)$, where $\bar{L}_m$ is the average value of the magnetizing inductance; $L_{\Delta m}$ is the half of amplitude of the sinusoidal variation of the magnetizing inductance.

The analytic expression for the $L_m(\theta_r)$ is needed. In general, this can be performed using the finite-element analysis with available high-performance software, for example, MATLAB, ANSYS, or MATHEMATICA. One can approximate these variations of $L_m(\theta_r)$ as $L_m\left(\theta_r\right) = \bar{L}_m - L_{\Delta m}\cos^n 2\theta_r$, $n = 1, 3, 5, \ldots$

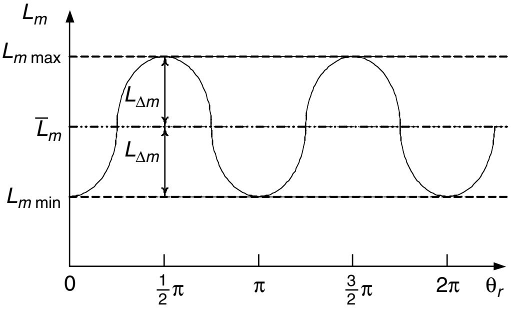

FIGURE 18.5.3 Magnetizing inductance $L_m(\theta_r) = \bar{L}_m - L_{\Delta m} f(\theta_r)$.

The electromagnetic torque, developed by single-phase reluctance nanomotors, is found using the expression for the co-energy as given by $W_c(i_{as},\theta_r) = \frac{1}{2} L_m(\theta_r) i_{as}^2$. Letting $L_m(\theta_r) = \bar{L}_m - L_{\Delta m}\cos 2\theta_r$, one finds

$$W_c(i_{as},\theta_r) = \tfrac{1}{2}\left(L_{ls} + \bar{L}_m - L_{\Delta m}\cos 2\theta_r\right) i_{as}^2$$

Thus, the synchronous reluctance nanomotor electromagnetic torque is given as

$$T_e = \frac{\partial W_c(i_{as},\theta_r)}{\partial \theta_r} = \frac{\partial\left(\frac{1}{2} i_{as}^2 \left(L_{ls} + \bar{L}_m - L_{\Delta m}\cos 2\theta_r\right)\right)}{\partial \theta_r} = L_{\Delta m} i_{as}^2 \sin 2\theta_r$$

The average value of T_e is not equal to zero if the current (magnetic field) is a function of the rotor angular displacement θ_r. As an illustration, let the following current be fed to the motor nanowinding $i_{as} = i_M \operatorname{Re}\left(\sqrt{\sin 2\theta_r}\right)$. Then, the electromagnetic torque is

$$T_e = L_{\Delta m} i_{as}^2 \sin 2\theta_r = L_{\Delta m} i_M^2 \left(\operatorname{Re}\sqrt{\sin 2\theta_r}\right)^2 \sin 2\theta_r \neq 0 \quad \text{and} \quad T_{eav} = \frac{1}{\pi}\int_0^{\pi} L_{\Delta m} i_{as}^2 \sin 2\theta_r d\theta_r = \tfrac{1}{4} L_{\Delta m} i_M^2$$

Making use of Kirchhoff's and Newton's second laws

$$u_{as} = r_s i_{as} + \frac{d\psi_{as}}{dt}, \quad T_e - B_m \omega_r - T_L = J\frac{d^2\theta_r}{dt^2}$$

and taking note of the flux linkage equation $\psi_{as} = \left(L_{ls} + \bar{L}_m - L_{\Delta m}\cos 2\theta_r\right) i_{as}$, one obtains a set of three nonlinear differential equations that models single-phase synchronous reluctance nanomotors as

$$\frac{di_{as}}{dt} = -\frac{r_s}{L_{ls} + \bar{L}_m - L_{\Delta m}\cos 2\theta_r} i_{as} - \frac{2L_{\Delta m}}{L_{ls} + \bar{L}_m - L_{\Delta m}\cos 2\theta_r} i_{as}\omega_r \sin 2\theta_r + \frac{1}{L_{ls} + \bar{L}_m - L_{\Delta m}\cos 2\theta_r} u_{as},$$

$$\frac{d\omega_r}{dt} = \frac{1}{J}\left(L_{\Delta m} i_{as}^2 \sin 2\theta_r - B_m \omega_r - T_L\right)$$

$$\frac{d\theta_r}{dt} = \omega_r$$

The lamped-parameters mathematical model developed is verified through nonlinear simulations. In particular, the 100 nm (length) × 100 nm (height) × 25 nm (width) synchronous nanomotor with 65 nm

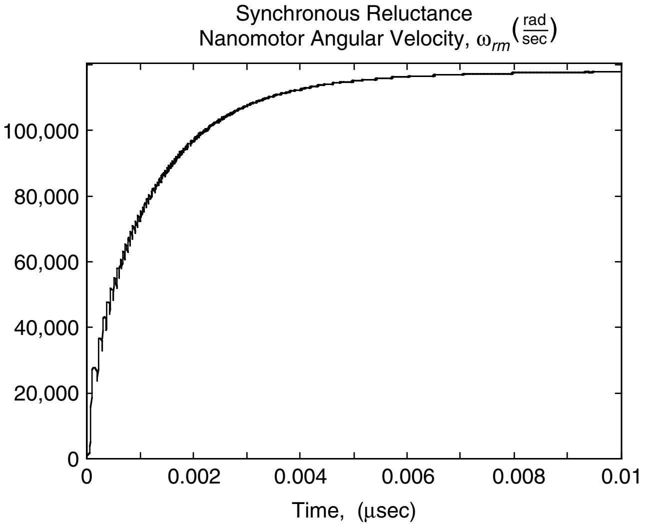

FIGURE 18.5.4 Acceleration of a synchronous reluctance nanomotor.

(length) × 25 nm (width) rotor is examined (see Figure 18.5.2). This nanomotor can be fabricated and nanowindings can be deposited using available nanotechnologies. The relative permeability of the ferromagnetic material was assumed to be $30000\mu_0$, and the friction was neglected. The ratio L_{md}/L_{mq} was assigned to be 4. This ratio significantly influences the electromagnetic torque developed. However, high L_{md}/L_{mq} ratio (to attain higher torque) results in torque ripple and vibrations. The simulation results are represented in Figure 18.5.4.

Maxwell's equations are used to attain high-fidelity modeling of nanomachines.[3] For example, the application of the magnetic potential as the variable gives the following equation to model the dynamics of synchronous reluctance nanomachines:

$$\sigma\frac{\partial \mathbf{A}_z}{\partial t}=\frac{\nabla^2\mathbf{A}_z}{\mu}-\sigma\mathbf{v}\left(\nabla\mathbf{A}_z\right)+\mathbf{J}$$

where $\mathbf{A}_z$ is the z-component of the magnetic potential; $\mathbf{v}$ is the velocity vector; $\mathbf{J}$ is the current density; and σ and μ are the conductivity and permeability.

In general, three-dimensional Maxwell's equations must be applied using conductivity and permeability tensors. These three-dimensional Maxwell's equations, integrated with the relationships for electromagnetic torque, *torsional-mechanical* dynamics, and virboacoustic transient behavior, must be used to model synchronous reluctance nanomachines. Utilizing this high-fidelity modeling concept, high electromagnetic loads and flux densities, saturation, hysteresis, high-frequency harmonics effects, eddy current losses, and other phenomena can be integrated and examined. Although this leads to formidable analytical and numerical difficulties, they can be resolved using high-performance software such as MATLAB.

The synchronous reluctance motors, though quite simple from the fabrication viewpoints, cannot guarantee high performance. As a result, other nanomachines are considered.

18.6 Permanent-Magnet Synchronous Nanomachines

Prototyping and Synthesis of Permanent-Magnet Synchronous Nanomachines

Despite the limited research, availability, and inconsistency, efficient permanent-magnet synchronous nanomachines can be synthesized utilizing the axial topology and endless electromagnetic system. In fact, high-performance axial topology micromachines have been synthesized, designed, tested and characterized.[3]

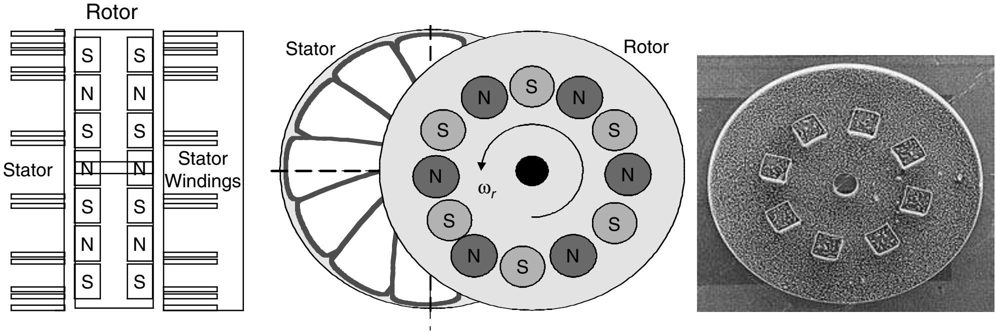

FIGURE 18.6.1 Axial permanent-magnet synchronous nanomachine.

Although these nanomachines are different compared with the *E. coli* nanobiomotor, which may not have permanent magnets, a similar topology is utilized. Furthermore, we progressed to the same well-defined and well-understood inorganic motion nanodevices that can be fabricated utilizing nanotechnology. The advantages of axial topology nanomachines are efficiency and reliability. Fabrication simplicity, affordability, and high-yield result because

1. Nanomagnets are flat (planar) without strict requirements on the surface roughness and uniformity.
2. There are no strict shape and magnetic properties requirements imposed on nanomagnets.
3. Rotor back ferromagnetic material is not required.
4. It is easy to deposit planar nanowires on the flat stator forming nanowindings.

Utilizing the axial topology and endless electromagnetic system, we synthesize permanent-magnet synchronous nanomachines. The synthesized nanomachine is reported in Figure 18.6.1. This nanomachine has well-defined topological analogy compared with the *E. coli* nanobiomotor. It must be emphasized that the documented motion nanodevice can be fabricated, and a prototype of the micromachine with 40 μm rotor was tested and characterized. The planar segmented nanomagnet array, as evident from Figure 18.6.1, can be deposited as thin films nanomagnets.

Modeling of Permanent-Magnet Synchronous Nanomachines

The prototyping and synthesis tasks have been reported and performed. As nanomachines are devised, the sequential analysis and design problems must be researched. In this section we develop an integrated electromagnetic-mechanical-vibroacoustic modeling, analysis, and optimization paradigm to comprehensively *assess and control* electromagnetic, electromechanical, and vibroacoustic phenomena in nanomachines. Our goal is to perform high-fidelity modeling to achieve the highest degree of confidence in simulation, guaranteeing accuracy. In particular, the problems to be researched are modeling (deviations of equations of motion to model complex phenomena and effects in the time domain), heterogeneous simulation, data-intensive analysis, and robust design.

The nanomachine electromagnetics, electromagnetic torque production, and energy conversion are examined. In nanomachines, vibration and noise result due to complex electromagnetic-electromechanical-vibroacoustic phenomena that are studied. Electromagnetic fields modeling is performed applying Maxwell's equations.[3] The following partial differential equations describe time-varying electromagnetic fields in motion nanodevices that are not based on quantum effects:

$$\nabla\times\mathbf{E}=-\mu\frac{\partial\mathbf{H}}{\partial t},\quad \nabla\times\mathbf{H}=\sigma\mathbf{E}+\mathbf{J},\quad \nabla\cdot\mathbf{E}=\frac{\rho_v}{\varepsilon},\quad \nabla\cdot\mathbf{H}=0$$

where **E** and **H** are the electric and magnetic field intensities; **J** is the current density; ε, μ, and σ are the permittivity, permeability, and conductivity tensors, respectively; and ρ_v is the volume charge density.

The Lorenz force, which relates the electromagnetic and mechanical phenomena, is given as

$$\mathbf{F}=\rho_v(\mathbf{E}+\mathbf{v}\times\mathbf{B})=\rho_v\mathbf{E}+\mathbf{J}\times\mathbf{B}$$

The electromagnetic force is found by applying the Maxwell stress tensor. This concept employs a volume integral to obtain the stored energy, and

$$\mathbf{F}=\int_v(\rho_v\mathbf{E}+\mathbf{J}\times\mathbf{B})dv=\frac{1}{\mu}\oint_s \overleftrightarrow{T}_s\cdot d\mathbf{s}$$

where the electromagnetic stress energy tensor is

$$T_s=T_s^E+T_s^M=\begin{bmatrix} E_1D_1-\frac{1}{2}E_jD_j & E_1D_2 & E_1D_3\\ E_2D_1 & E_2D_2-\frac{1}{2}E_jD_j & E_2D_3\\ E_3D_1 & E_3D_2 & E_3D_3-\frac{1}{2}E_jD_j\end{bmatrix}$$

$$+\begin{bmatrix} B_1H_1-\frac{1}{2}B_jH_j & B_1H_2 & B_1H_3\\ B_2H_1 & B_2H_2-\frac{1}{2}B_jH_j & B_2H_3\\ B_3H_1 & B_3H_2 & B_3H_3-\frac{1}{2}B_jH_j\end{bmatrix}.$$

For two regions (air gap *ag* and permanent magnets *pm*), we have the air gap and permanent magnet flux densities as

$$\mathbf{B}_{ag}=\mu_0\mathbf{H}_{ag}\quad\text{and}\quad\mathbf{B}_{pm}=\mu_0\mathbf{H}_{pm}+\mathbf{J}=\mu_0(\mu_r\mathbf{H}_{pm}+\mathbf{M})$$

where **M** is the residual magnetization vector, $M = B_r/\mu_0\mu_r$; B_r is the remanence; and μ_r is the relative recoil permeability.

The negative gradient of the scalar magnetic potential V gives the magnetic field intensity, for example,

$$\mathbf{H}=-\nabla V$$

The scalar magnetic potential satisfies the Laplace equation in free and homogeneous media (with zero current density and $\mathbf{J} = 0$). For axial topology nanomachines, the cylindrical coordinate system is used. We have the equation

$$\nabla\cdot\mathbf{M}=\frac{1}{r}\frac{\partial(rM_r)}{\partial r}+\frac{1}{r}\frac{\partial M_\phi}{\partial r}+\frac{\partial M_z}{\partial z}$$

Solving the partial differential equation[3,7]

$$\frac{1+\chi_t}{r}\frac{\partial}{\partial r}\left(r\frac{\partial V}{\partial r}\right)+\frac{1+\chi_t}{r^2}\frac{\partial^2 V}{\partial\phi^2}+(1+\chi)\frac{\partial^2 V_{ag}}{\partial z^2}=\nabla\cdot\mathbf{M},$$

the three-dimensional air-gap flux density is found as

$$B_{ag\,z}(r,\phi,z)=\frac{\mu_0M_0}{1+\chi}\sum_{i=1}^{\infty}a_i\frac{\sinh\dfrac{v_i\varepsilon h_r}{r}}{\sinh\dfrac{v_i\varepsilon(h_r+g_{ag})}{r}}\cosh\frac{v_i\varepsilon z}{r}\sin v_i\phi$$

where χ and χ_t are the reversible susceptibility along the easy and transverse magnetization axes; a_i is the harmonic amplitude coefficient, and for the trapezoidal-wave magnetization,

$$a_i = \frac{4\sin(2i-1)}{\pi(2i-1)^2};$$

$h_r \le z \le g_{ag} + h_r$, h_r is the rotor thickness.

One-dimensional air-gap flux density is found to be

$$B_{ag\,z}(\phi) = \frac{\mu_0 M_0 h_r}{(1+\chi)(h_r + g_{ag})} \sum_{i=1}^{\infty} a_i \sin v_i \phi \; .$$

Thus, the maximum flux density in the air gap is

$$B_{\max z} = \frac{\mu_0 M_0 h_r}{(1+\chi)(h_r + g_{ag})} \sum_{i=1}^{\infty} a_i (-1)^{i+1} \; .$$

Using the derived equations for the air-gap flux and *emf*

$$emf = \oint \mathbf{E} d\mathbf{l} = -\int_s \frac{\partial \mathbf{B}}{\partial t} \cdot d\mathbf{s}$$

one finds three-dimensional electromagnetic model for nanomachines dynamics, torque production, and vibration. It should be emphasized that the electromagnetic torque is given as

$$\mathbf{T} = \mathbf{m} \times \mathbf{B}$$

The radiated pressure $p(r, \theta, \phi, t)$ is found using the Green function G. We have

$$p(r,\theta,\phi,t) = \rho \int_0^{2\pi} \int_{-R}^{+R} \ddot{\omega}(\phi,z,t) G(r,\theta,\phi) d\phi dz$$

the developed equations of motion model electromagnetic-mechanical-vibroacoustic behavior of synchronous electromagnetic nanomachines.

Optimization of Permanent-Magnet Synchronous Nanomachines

One must attain optimal electromagnetic, mechanical, and vibroacoustic behavior of all nanomachines, including permanent-magnet synchronous motion nanodevices. The electromagnetic and mechanical design is based on the application of Maxwell's equations and tensor calculus in order to optimize the complex electromechanical behavior in nanomachines. For example, the nanomachine electromagnetic system, components (magnets, windings, air gap, etc.) and geometry can be optimized to maximize efficiency (η) and robustness, maximizing the electromagnetic torque (T_e), as well as minimize torque ripple ($\boldsymbol{T}_{er}$), undesirable torque components (T_x and T_y), vibroacoustic signature (p), losses, and so forth. In addition to the *passive optimization*, the *active optimization control* problem can formulated and examined to ensure optimal *achievable* performance. It should be emphasized that although the designer may want to attain the ideal characteristics and performance, usually they cannot be achieved simply due to the physical limits imposed (power and torque densities, current density, angular velocity, etc.).

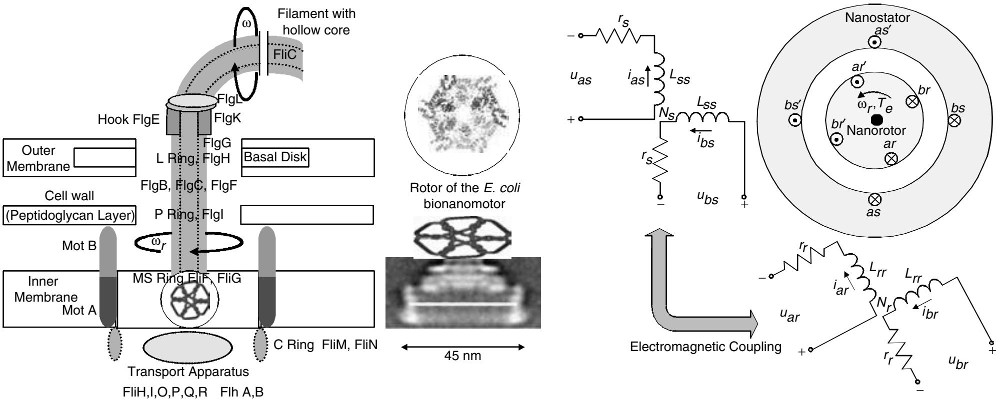

FIGURE 18.7.1 *E. coli* nanobiomotor with assumed short-circuited rotor nanobiowindings and two-phase induction nanomachine.

The mathematical formulation of the active optimization control problem is given as the mini-max nonlinear optimization formulation, for example,

$$\max_{\mathbf{u}\in U} \min\left[\eta, T_e, \mathbf{T}_{er}, T_x, T_y, p(t,r,\theta,\phi)\right]$$

where **u** is the control vector.

Different control variables can be used. For axial and radial topology synchronous nanomachines, the electro-magnetic field is controlled by varying applied phase voltages.

18.7 Induction Nanomachines

Prototyping and Synthesis of Induction Nanomachines

Complex three-dimensional organic complexes and assemblies in *E. coli* and *Salmonella typhimurium* bacteria were studied in this chapter. For example, the 45 nm *E. coli* nanorotor is built as the so-called MS ring that consists of FliF and FliG proteins. These proteins' geometry and folding are unknown. One can assume that short-circuited nanowindings can be formed by these proteins. It should be emphasized that complex three-dimensional organic circuits (windings) can be engineered.[6] As another example, consider the AAA (ATPases Associated with various cellular Activities) interacting protein superfamily. This AAA protein superfamily is characterized by a highly conserved module of more than 230 amino acid residues, including an ATP binding consensus, present in one or two copies in the AAA proteins. The AAA proteins are found in all organisms and are essential for their functionality. The specific attention should be focused on the geometry and folding of different protein complexes and assemblies. In addition, the *E. coli* nanobiomotor and synthesized nanomachines can operate as induction nanomachines; see Figure 18.7.1.

Modeling of Induction Nanomachines

By making use the documented results, the studied two-phase induction nanomachine is illustrated in Figure 18.7.1. The control variables are the phase voltages u_{as} and u_{bs}. To develop lumped-parameter mathematical models of induction nanomachines, we model the stator and rotor circuitry dynamics. As the variables, the voltages applied to the stator and rotor windings (*as*, *bs* and *ar*, *br*, respectively) as well as the stator and rotor currents and flux linkages are used. Using Kirchhoff's voltage law, four differential equations are found to be

- Stator circuitry $u_{as}=r_s i_{as}+\frac{d\psi_{as}}{dt}$ and $u_{bs}=r_s i_{bs}+\frac{d\psi_{bs}}{dt}$
- Rotor circuitry $u_{ar}=r_r i_{ar}+\frac{d\psi_{ar}}{dt}$ and $u_{br}=r_r i_{br}+\frac{d\psi_{br}}{dt}$

Here, the nanomachine variables are the phase voltage, current, and flux linkages u_{as}, u_{bs}, u_{ar}, u_{br}, i_{as}, i_{bs}, i_{ar}, i_{br}, ψ_{as}, ψ_{bs}, ψ_{ar} and ψ_{br}.

The nanomachine parameters are the resistances of the stator and rotor windings r_s and r_r.

The flux linkages are expressed using the phase currents and inductances that are functions of rotor angular displacement. We have

$$\begin{bmatrix}\psi_{as}\\ \psi_{bs}\\ \psi'_{ar}\\ \psi'_{br}\end{bmatrix}=\begin{bmatrix}L_{ss} & 0 & L_{ms}\cos\theta_r & -L_{ms}\sin\theta_r\\ 0 & L_{ss} & L_{ms}\sin\theta_r & L_{ms}\cos\theta_r\\ L_{ms}\cos\theta_r & L_{ms}\sin\theta_r & L'_{rr} & 0\\ -L_{ms}\sin\theta_r & L_{ms}\cos\theta_r & 0 & L'_{rr}\end{bmatrix}\begin{bmatrix}i_{as}\\ i_{bs}\\ i'_{ar}\\ i'_{br}\end{bmatrix}$$

where θ_r is the angular displacement; L_{ss} and L_{rr} are the self-inductances of the stator and rotor windings; L_{ms} is the stator magnetizing inductance; and L_{ls} and L_{lr} are the stator and rotor leakage inductances.

The number of turns in the stator and rotor windings are used. We have the expressions

$$i'_{ar}=\frac{N_r}{N_s}i_{ar},\, i'_{br}=\frac{N_r}{N_s}i_{br}\;,\quad u'_{ar}=\frac{N_r}{N_s}u_{ar},\, u'_{br}=\frac{N_r}{N_s}u_{br}\;,\quad \psi'_{ar}=\frac{N_r}{N_s}\psi_{ar},\, \psi'_{br}=\frac{N_r}{N_s}\psi_{br}$$

Taking note of the turn ratio, we have the following expressions for inductances and rotor resistance:

$$L'_{mr}=L_{ms}=\frac{N_s}{N_r}L_{sr},\, L'_{rr}=L'_{lr}+L_{ms}\quad\text{and}\quad r'_r=\frac{N_s^2}{N_r^2}r_r$$

One obtains the following set of nonlinear differential equations in Cauchy's form to model the stator-rotor circuitry dynamics of induction nanomachines:

$$\begin{aligned}\frac{di_{as}}{dt}=&-\frac{L'_{rr}r_s}{L_{ss}L'_{rr}-L_{ms}^2}i_{as}+\frac{L_{ms}^2}{L_{ss}L'_{rr}-L_{ms}^2}i_{bs}\omega_r+\frac{L_{ms}L'_{rr}}{L_{ss}L'_{rr}-L_{ms}^2}i'_{ar}\left(\omega_r\sin\theta_r+\frac{r'_r}{L'_{rr}}\cos\theta_r\right)\\&+\frac{L_{ms}L'_{rr}}{L_{ss}L'_{rr}-L_{ms}^2}i'_{br}\left(\omega_r\cos\theta_r-\frac{r'_r}{L'_{rr}}\sin\theta_r\right)+\frac{L'_{rr}}{L_{ss}L'_{rr}-L_{ms}^2}u_{as}-\frac{L_{ms}}{L_{ss}L'_{rr}-L_{ms}^2}\cos\theta_r u'_{ar}\\&+\frac{L_{ms}}{L_{ss}L'_{rr}-L_{ms}^2}\sin\theta_r u'_{br},\end{aligned}$$

$$\begin{aligned}\frac{di_{bs}}{dt}=&-\frac{L'_{rr}r_s}{L_{ss}L'_{rr}-L_{ms}^2}i_{bs}-\frac{L_{ms}^2}{L_{ss}L'_{rr}-L_{ms}^2}i_{as}\omega_r-\frac{L_{ms}L'_{rr}}{L_{ss}L'_{rr}-L_{ms}^2}i'_{ar}\left(\omega_r\cos\theta_r-\frac{r'_r}{L'_{rr}}\sin\theta_r\right)\\&+\frac{L_{ms}L'_{rr}}{L_{ss}L'_{rr}-L_{ms}^2}i'_{br}\left(\omega_r\sin\theta_r+\frac{r'_r}{L'_{rr}}\cos\theta_r\right)+\frac{L'_{rr}}{L_{ss}L'_{rr}-L_{ms}^2}u_{bs}-\frac{L_{ms}}{L_{ss}L'_{rr}-L_{ms}^2}\sin\theta_r u'_{ar}\\&-\frac{L_{ms}}{L_{ss}L'_{rr}-L_{ms}^2}\cos\theta_r u'_{br},\end{aligned}$$

$$\frac{di'_{ar}}{dt} = -\frac{L_{ss}r'_r}{L_{ss}L'_{rr}-L_{ms}^2} i'_{ar} + \frac{L_{ms}L_{ss}}{L_{ss}L'_{rr}-L_{ms}^2} i_{as}\left(\omega_r \sin\theta_r + \frac{r_s}{L_{ss}}\cos\theta_r\right) - \frac{L_{ms}L_{ss}}{L_{ss}L'_{rr}-L_{ms}^2} i_{bs}\left(\omega_r \cos\theta_r - \frac{r_s}{L_{ss}}\sin\theta_r\right)$$
$$-\frac{L_{ms}^2}{L_{ss}L'_{rr}-L_{ms}^2} i'_{br}\omega_r - \frac{L_{ms}}{L_{ss}L'_{rr}-L_{ms}^2}\cos\theta_r u_{as} - \frac{L_{ms}}{L_{ss}L'_{rr}-L_{ms}^2}\sin\theta_r u_{bs} + \frac{L_{ss}}{L_{ss}L'_{rr}-L_{ms}^2} u'_{ar},$$

$$\frac{di'_{br}}{dt} = -\frac{L_{ss}r'_r}{L_{ss}L'_{rr}-L_{ms}^2} i'_{br} + \frac{L_{ms}L_{ss}}{L_{ss}L'_{rr}-L_{ms}^2} i_{as}\left(\omega_r \cos\theta_r - \frac{r_s}{L_{ss}}\sin\theta_r\right) + \frac{L_{ms}L_{ss}}{L_{ss}L'_{rr}-L_{ms}^2} i_{bs}\left(\omega_r \sin\theta_r + \frac{r_s}{L_{ss}}\cos\theta_r\right)$$
$$+\frac{L_{ms}^2}{L_{ss}L'_{rr}-L_{ms}^2} i'_{ar}\omega_r + \frac{L_{ms}}{L_{ss}L'_{rr}-L_{ms}^2}\sin\theta_r u_{as} - \frac{L_{ms}}{L_{ss}L'_{rr}-L_{ms}^2}\cos\theta_r u_{bs} + \frac{L_{ss}}{L_{ss}L'_{rr}-L_{ms}^2} u'_{br}.$$

In these differential equations, the angular velocity ω_r and displacement θ_r are used as the state variables. Therefore, the *torsional-mechanical* equation of motion must be incorporated to describe the evolution of induction nanomachines in the time domain. From Newton's second law for rotational motion, we have the following differential equations:

$$\frac{d\omega_r}{dt} = \frac{1}{J}\left(T_e - B_m\omega_r - T_L\right)$$
$$\frac{d\theta_r}{dt} = \omega_r$$

The electromagnetic torque developed by induction nanomotors must be found. Using the co-energy W_c,[3] one has the following relationship for the electromagnetic torque:

$$T_e = \frac{P}{2}\frac{\partial W_c\left(\mathbf{i}_{abs}, \mathbf{i}'_{abr}, \theta_r\right)}{\partial\theta_r} = \frac{P}{2}\mathbf{i}_{abs}^T\frac{\partial \mathbf{L}'_{sr}(\theta_r)}{\partial\theta_r}\mathbf{i}'_{abr} = \frac{P}{2}L_{ms}\begin{bmatrix} i_{as} & i_{bs}\end{bmatrix}\begin{bmatrix} -\sin\theta_r & -\cos\theta_r \\ \cos\theta_r & -\sin\theta_r\end{bmatrix}\begin{bmatrix} i'_{ar} \\ i'_{br}\end{bmatrix}$$
$$= -\frac{P}{2}L_{ms}\left[\left(i_{as}i'_{ar} + i_{bs}i'_{br}\right)\sin\theta_r + \left(i_{as}i'_{br} - i_{bs}i'_{ar}\right)\cos\theta_r\right],$$

where P is the number of poles.

Thus, the *torsional-mechanical* equations of motion are found to be

$$\frac{d\omega_r}{dt} = -\frac{P^2}{4J}L_{ms}\left[\left(i_{as}i'_{ar} + i_{bs}i'_{br}\right)\sin\theta_r + \left(i_{as}i'_{br} - i_{bs}i'_{ar}\right)\cos\theta_r\right] - \frac{B_m}{J}\omega_r - \frac{P}{2J}T_L,$$
$$\frac{d\theta_r}{dt} = \omega_r$$

It should be emphasized that the angular velocity of nanobiomotors is low whereas the output torque is high. In particular, the angular velocity of the *E. coli* nanobiomotor is 20 rad/sec. This suggests that the number of poles may be high. In fact, the output angular velocity of nanomachine is $\omega_{rm} = \frac{2}{P}\omega_r$, and the output torque is given as $T_{em} = \frac{P}{2}T_e$.

Two *torsional-mechanical* differential equations are integrated with the circuitry dynamics to derive a set of nonlinear differential equations to model two-phase induction nanomotors.

Simulation of Induction Nanomachines

The mathematical model developed is verified performing analysis and examining the transient dynamics and steady-state operation. We study an induction nanomotor with 100 nm stator outer diameter. The

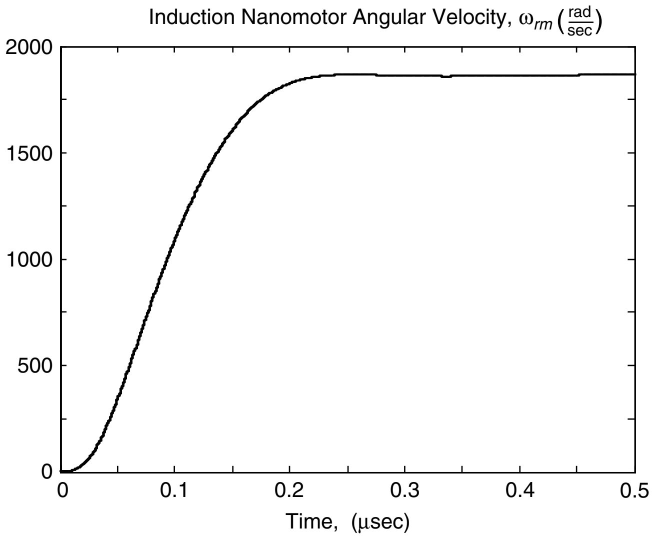

FIGURE 18.7.2 Acceleration of a 100 nm induction nanomotor.

nanomotor parameters are obtained using the dimension estimates, as well as technologies, processes, and materials that can be potentially used to fabricate this nanomachine. In particular, the stator and rotor resistances are found to be $r_s = 3125$ ohm and $r_r = 1890$ ohm. The stator magnetizing inductance is $L_{ms} = 0.000035$ H, whereas the stator and rotor leakage inductances are estimated to be $L_{ls} = L_{lr} = 3 \times 10^{-6}$ H. The friction is neglected ($B_m = 0$), and $P = 2$. The rated phase voltages and currents are estimated to be 3×10^{-3} V and 1 μA, respectively.

The corresponding files to simulate and analyze this induction nanomachine are developed in MATLAB. The angular velocity response (transient dynamics) is illustrated in Figure 18.7.2. It must be emphasized that the angular velocity is controlled by changing the frequency of the phase voltages. The simulations are performed for an open-loop induction nanomotor without a controller, and the limits on the variables are integrated. The peak phase currents are 3 μA. The simulation results illustrate that the induction nanomotor reaches the rated angular velocity within 0.22 μsec. Although, in general additional nonlinear effects should be integrated in the modeling and analysis of nanomachines (nonlinear magnetization, hysteresis, vibration, friction, etc.), the realistic results are obtained.

18.8 Conclusions

This chapter researches benchmarking engineering problems in synthesis, design, and analysis of electromagnetic-based nanomachines and motion nanodevices. This complements the nanotechnology in many ways. In particular, high-performance motion nano- and microdevices have been challenged the society for 50 years, and very limited progress has been achieved to date. Different nanomachines that have analogies and equivalence in nanobiomotors were proposed, prototyped, classified, and examined. The synthesis and classification solver can be applied to devise, refine (modify), and classify novel nanomachines. Accurate assessment of nanomachine performance depends on mathematical models used in design and analysis. Therefore, high-fidelity mathematical models of nanomachines were developed. These electromechanical models were found in the form of nonlinear differential equations. The derived equations of motion allow the designer to study the dynamic and steady-state behavior of nanomachines. This chapter performs fundamental and applied research in response to long-standing unsolved basic problems, engineering enterprise, and emerging evolutionary demands in synthesis of high-performance affordable nanomachines and motion nanodevices. It is important that the reported nanomachines can be fabricated achieving affordable high-yield fabrications due to simplicity, feasibility, and viability of the motion nanodevices documented.

International System of Units (SI)

The International System of units (SI) was adopted by the 11th General Conference on Weights and Measures (CGPM) in 1960. It is a coherent system of units built from seven *SI base units,* one for each of the seven dimensionally independent base quantities: the meter, kilogram, second, ampere, kelvin, mole, and candela, for the dimensions length, mass, time, electric current, thermodynamic temperature, amount of substance, and luminous intensity, respectively. The definitions of the SI base units are given below. The *SI derived units* are expressed as products of powers of the base units, analogous to the corresponding relations between physical quantities but with numerical factors equal to unity.

In the International System there is only one SI unit for each physical quantity. This is either the appropriate SI base unit itself or the appropriate SI derived unit. However, any of the approved decimal prefixes, called *SI prefixes,* may be used to construct decimal multiples or submultiples of SI units.

It is recommended that only SI units be used in science and technology (with SI prefixes where appropriate). Where there are special reasons for making an exception to this rule, it is recommended always to define the units used in terms of SI units. This section is based on information supplied by IUPAC.

Definitions of SI Base Units

Meter: The meter is the length of path traveled by light in vacuum during a time interval of 1/299 792 458 of a second (17th CGPM, 1983).

Kilogram: The kilogram is the unit of mass; it is equal to the mass of the international prototype of the kilogram (3rd CGPM, 1901).

Second: The second is the duration of 9 192 631 770 periods of the radiation corresponding to the transition between the two hyperfine levels of the ground state of the cesium-133 atom (13th CGPM, 1967).

Ampere: The ampere is that constant current which, if maintained in two straight parallel conductors of infinite length, of negligible circular cross section, and placed 1 meter apart in vacuum, would produce between these conductors a force equal to 2×10^{-7} newton per meter of length (9th CGPM, 1958).

Kelvin: The kelvin, unit of thermodynamic temperature, is the fraction 1/273.16 of the thermodynamic temperature of the triple point of water (13th CGPM, 1967).

Mole: The mole is the amount of substance of a system which contains as many elementary entities as there are atoms in 0.012 kilogram of carbon-12. When the mole is used, the elementary entities must be specified and may be atoms, molecules, ions, electrons, or other particles, or specified groups of such particles (14th CGPM, 1971). Examples of the use of the mole:

- 1 mol of H_2 contains about 6.022×10^{23} H_2 molecules, or 12.044×10^{23} H atoms.
- 1 mol of HgCl has a mass of 236.04 g.
- 1 mol of Hg_2Cl_2 has a mass of 472.08 g.
- 1 mol of Hg_2^{2+} has a mass of 401.18 g and a charge of 192.97 kC.
- 1 mol of $Fe_{0.91}$ S has a mass of 82.88 g.
- 1 mol of e^- has a mass of 548.60 μg and a charge of –96.49 kC.
- 1 mol of photons whose frequency is 10^{14} Hz has energy of about 39.90 kJ.

Candela: The candela is the luminous intensity, in a given direction, of a source that emits monochromatic radiation of frequency 540×10^{12} Hz and that has a radiant intensity in that direction of (1/683) watt per steradian (16th CGPM, 1979).

Names and Symbols for the SI Base Units

Physical Quantity	Name of SI Unit	Symbol for SI Unit

Amount of substance	mole	mol
Luminous intensity	candela	cd

SI Derived Units with Special Names and Symbols

Physical Quantity	Name of SI Unit	Symbol for SI Unit	Expression in Terms of SI Base Units
Frequency[a]	hertz	Hz	s^{-1}
Force	newton	N	$m \cdot kg \cdot s^{-2}$
Pressure, stress	pascal	Pa	$N \cdot m^{-2} = m^{-1} \cdot kg \cdot s^{-2}$
Energy, work, heat	joule	J	$N \cdot m = m^2 \cdot kg \cdot s^{-2}$
Power, radiant flux	watt	W	$J \cdot s^{-1} = m^2 \cdot kg \cdot s^{-3}$
Electric charge	coulomb	C	$A \cdot s$

Physical Quantity	Name of SI Unit	Symbol for SI Unit	Expression in Terms of SI Base Units
Electric potential, electromotive force	volt	V	$\mathrm{J \cdot C^{-1} = m^2 \cdot kg \cdot s^{-3} \cdot A^{-1}}$
Electric resistance	ohm	Ω	$\mathrm{V \cdot A^{-1} = m^2 \cdot kg \cdot s^{-3} \cdot A^{-2}}$
Electric conductance	siemens	S	$\mathrm{\Omega^{-1} = m^{-2} \cdot kg^{-1} \cdot s^4 \cdot A^2}$
Electric capacitance	farad	F	$\mathrm{C \cdot V^{-1} = m^{-2} \cdot kg^{-1} \cdot s^4 \cdot A^2}$
Magnetic flux density	tesla	T	$\mathrm{V \cdot s \cdot m^{-2} = kg \cdot s^{-2} \cdot A^{-1}}$
Magnetic flux	weber	Wb	$\mathrm{V \cdot s = m^2 \cdot kg \cdot s^{-2} \cdot A^{-1}}$
Inductance	henry	H	$\mathrm{V \cdot A^{-1} \cdot s = m^2 \cdot kg \cdot s^{-2} \cdot A^{-2}}$
Celsius temperature[b]	degree Celsius	°C	K
Luminous flux	lumen	lm	$\mathrm{cd \cdot sr}$
Illuminance	lux	lx	$\mathrm{cd \cdot sr \cdot m^{-2}}$
Activity (radioactive)	becquerel	Bq	$\mathrm{s^{-1}}$
Absorbed dose (or radiation)	gray	Gy	$\mathrm{J \cdot kg^{-1} = m^2 \cdot s^{-2}}$
Dose equivalent (dose equivalent index)	sievert	Sv	$\mathrm{J \cdot kg^{-1} = m^2 \cdot s^{-2}}$
Plane angle	radian	rad	$\mathrm{1 = m \cdot m^{-1}}$
Solid angle	steradian	sr	$\mathrm{1 = m^2 \cdot m^{-2}}$

[a] For radial (circular) frequency and for angular velocity the unit rad $\mathrm{s^{-1}}$, or simply $\mathrm{s^{-1}}$, should be used, and this may not be simplified to Hz. The unit Hz should be used only for frequency in the sense of cycles per second.

[b] The Celsius temperature θ is defined by the equation

$$q/{}^\circ\mathrm{C} = T/\mathrm{K} = 237.15$$

The SI unit of Celsius temperature interval is the degree Celsius, °C, which is equal to the kelvin, K. °C should be treated as a single symbol, with no space between the ° sign and the letter C. (The symbol °K, and the symbol °, should no longer be used.)

Units in Use Together with the SI

These units are not part of the SI, but it is recognized that they will continue to be used in appropriate contexts. SI prefixes may be attached to some of these units, such as milliliter, ml; millibar, mbar; megaelectronvolt, MeV; and kilotonne, kt.

Physical Quantity	Name of Unit	Symbol for Unit	Value in SI Units
Time	minute	min	60 s
Time	hour	h	3600 s
Time	day	d	86 400 s
Plane angle	degree	°	(π/180) rad
Plane angle	minute	′	(π/10 800) rad
Plane angle	second	″	(π/648 000) rad
Length	angstrom[a]	Å	10^{-10} m
Area	barn	b	10^{-28} m^2
Volume	liter	l, L	$\mathrm{dm^3 = 10^{-3}\ m^3}$
Mass	tonne	t	$\mathrm{Mg = 10^3\ kg}$
Pressure	bar[a]	bar	$\mathrm{10^5\ Pa = 10^5\ N \cdot m^{-2}}$
Energy	electronvolt[b]	eV (= $e \times$ V)	$\approx 1.60218 \times 10^{-19}$ J
Mass	unified atomic mass unit[b,c]	u (= m_a(12C)/12)	$\approx 1.66054 \times 10^{-27}$ kg

[a] The angstrom and the bar are approved by CIPM for "temporary use with SI units," until CIPM makes a further recommendation. However, they should not be introduced where they are not used at present.

[b] The values of these units in terms of the corresponding SI units are not exact, since they depend on the values of the physical constants e (for the electronvolt) and N_A (for the unified atomic mass unit), which are determined by experiment.

[c] The unified atomic mass unit is also sometimes called the dalton, with symbol Da, although the name and symbol have not been approved by CGPM.

Conversion Constants and Multipliers

Recommended Decimal Multiples and Submultiples

Multiple or Submultiple	Prefix	Symbol	Multiple or Submultiple	Prefix	Symbol
10^{18}	exa	E	10^{-1}	deci	d
10^{15}	peta	P	10^{-2}	centi	c
10^{12}	tera	T	10^{-3}	milli	m
10^{9}	giga	G	10^{-6}	micro	μ (Greek mu)
10^{6}	mega	M	10^{-9}	nano	n
10^{3}	kilo	k	10^{-12}	pico	p

Temperature Factors

$$°\mathrm{F} = 9/5(°\mathrm{C}) + 32$$

$$\text{Fahrenheit temperature} = 1.8(\text{temperature in kelvins}) - 459.67$$

$$°\mathrm{C} = 5/9\left[(°\mathrm{F}) - 32\right]$$

$$\text{Celsius temperature} = \text{temperature in kelvins} - 273.15$$

$$\text{Fahrenheit temperature} = 1.8(\text{Celsius temperature}) + 32$$

Conversion of Temperatures

From	To		From	To	
Fahrenheit	Celcius	$t_C = \frac{t_F - 32}{1.8}$	Celsius	Fahrenheit	$t_F = (t_c \times 1.8) + 32$
				Kelvin	$T_K = t_c + 273.15$
				Rankine	$T_R = (t_c + 273.15) \times 18$
	Kelvin	$T_k = \frac{t_F - 32}{1.8} + 273.15$	Kelvin	Celsius	$t_c = T_K - 273.15$
				Rankine	$T_R = T_k \times 1.8$
	Rankine	$T_R = t_F + 459.67$	Rankine	Fahrenheit	$t_F = T_R - 459.67$
				Kelvin	$T_K = \frac{T_R}{1.8}$

Physical Constants

General

Equatorial radius of the earth = 6378.388 km = 3963.34 miles (statute)
Polar radius of the earth = 6356.912 km = 3949.99 miles (statute)
1 degree of latitude at 40° = 69 miles
1 international nautical mile = 1.150 78 miles (statute) = 1852 m = 6076.115 ft
Mean density of the earth = 5.522 g/cm^3 = 344.7 lb/ft^3
Constant of gravitation $(6.673 \pm 0.003) \times 10^{-8} \cdot \text{cm}^3 \cdot \text{g}^{-1} \cdot \text{s}^{-2}$
Acceleration due to gravity at sea level, latitude 45° = 980.6194 cm/s^2 = 32.1726 ft/s^2
Length of seconds pendulum at sea level, latitude 45° = 99.3575 cm = 39.1171 in.
1 knot (international) = 101.269 ft/min = 1.6878 ft/s = 1.1508 miles (statute)/h
1 micron = 10^{-4} cm
1 angstrom = 10^{-8} cm
Mass of hydrogen atom = $(1.673\,39 \pm 0.0031) \times 10^{-24}$ g
Density of mercury at 0°C = 13.5955 g/mL
Density of water at 3.98°C = 1.000 000 g/mL
Density, maximum, of water, at 3.98°C = 0.999 973 g/cm^3
Density of dry air at 0°C, 760 mm = 1.2929 g/L
Velocity of sound in dry air at 0°C = 331.36 m/s – 1087.1 ft/s
Velocity of light in vacuum = $(2.997\,925 \pm 0.000\,002) \times 10^{10}$ cm/s
Heat of fusion of water, 0°C = 79.71 cal/g
Heat of vaporization of water, 100°C = 539.55 cal/g
Electrochemical equivalent of silver 0.001 118 g/s international amp
Absolute wavelength of red cadmium light in air at 15°C, 760 mm pressure = 6438.4696 Å
Wavelength of orange-red line of krypton 86 = 6057.802 Å

π Constants

Symbols and Terminology for Physical and Chemical Quantities

Name	Symbol	Definition	SI Unit
	Classical Mechanics		
Mass	m		kg
Reduced mass	μ	$\mu = m_1 m_2/(m_1 + m_2)$	kg
Density, mass density	ρ	$\rho = m/V$	$\mathrm{kg \cdot m^{-3}}$
Relative density	d	$d = \rho/\rho^\theta$	1
Surface density	ρ_A, ρ_S	$\rho_a = m/A$	$\mathrm{kg \cdot m^{-2}}$
Specific volume	ν	$\nu = V/m = 1/\rho$	$\mathrm{m^3 \cdot kg^{-1}}$
Momentum	p	$\mathrm{p} = mv$	$\mathrm{kg \cdot m \cdot s^{-1}}$
Angular momentum, action	L	$\mathrm{L} = r \times p$	$\mathrm{J \cdot s}$
Moment of inertia	I, J	$I = \Sigma\, m_i\, r_i^2$	$\mathrm{kg \cdot m^2}$
Force	F	$\mathrm{F} = d\,\mathrm{p}/d\,t = m\,\mathrm{a}$	N
Torque, moment of a force	T, (M)	$\mathrm{T} = r \times F$	$\mathrm{N \cdot m}$
Energy	E		J
Potential energy	E_p, V, Φ	$E_p = \int \mathrm{F} \cdot ds$	J
Kinetic energy	E_k, T, K	$E_k = (1/2)\, mv^2$	J
Work	W, w	$W = \int \mathrm{F} \cdot ds$	J
Hamilton function	H	$H(q,p) = T(q,p) + V(q)$	J
Lagrange function	L	$L(q,\dot{q}) = T(q,\dot{q}) - V(q)$	J
Pressure	p, P	$p = F/A$	Pa, $\mathrm{N \cdot m^{-2}}$
Surface tension	γ, σ	$\gamma = dW/dA$	$\mathrm{N \cdot m^{-1}, J \cdot m^{-1}}$
Weight	$G\ (W, P)$	$G = mg$	N
Gravitational constant	G	$F = Gm_1 m_2/r^2$	$\mathrm{N \cdot m^2 \cdot kg^{-2}}$
Normal stress	σ	$\sigma = F/A$	Pa
Shear stress	τ	$\tau = F/A$	Pa
Linear strain, relative elongation	ε, e	$\varepsilon = \Delta l/1$	1
Modulus of elasticity, Young's modulus	E	$E = \sigma/\varepsilon$	Pa
Shear strain	γ	$\gamma = \Delta x/d$	1
Shear modulus	G	$\mathrm{G} = \tau/\gamma$	Pa
Volume strain, bulk strain	θ	$\theta = \Delta V/V_0$	1
Bulk modulus, compression modulus	K	$K = V_0(dp/dV)$	Pa
Viscosity, dynamic viscosity	η, μ	$\tau_{x,z} = \eta(dv_x/dz)$	$\mathrm{Pa \cdot s}$
Fluidity	ϕ	$\phi = \mathrm{l}/\eta$	$\mathrm{m \cdot kg^{-1} \cdot s}$
Kinematic viscosity	ν	$\nu = \eta/\rho$	$\mathrm{m^2 \cdot s^{-1}}$
Friction coefficient	$\mu, (f)$	$F_{\mathrm{frict}} = \mu F_{\mathrm{norm}}$	1
Power	P	$P = dW/dt$	W
Sound energy flux	P, P_a	$P = dE/dt$	W
Acoustic factors			
Reflection factor	ρ	$\rho = P_r/P_0$	1
Acoustic absorption factor	$\alpha_a, (\alpha)$	$\alpha_a = 1 - \rho$	1
Transmission factor	τ	$\tau = P_u/P_0$	1
Dissipation factor	δ	$\delta = \alpha_a - \tau$	1

Name	Symbol	Definition	SI Unit
		Classical Mechanics	
		Electricity and Magnetism	
Quantity of electricity, electric range	Q		C
Charge density	ρ	$\rho = Q/V$	$C \cdot m^{-3}$
Surface charge density	σ	$\sigma = Q/A$	$C \cdot m^{-2}$
Electric potential	V, ϕ	$V = dW/dQ$	$V, J \cdot C^{-1}$
Electric potential difference	$U, \Delta V, \Delta\phi$	$U = V_2 - V_1$	V
Electromotive force	E	$E = \int(F/Q) \cdot ds$	V
Electric field strength	E	$E = F/Q = -\text{grad } V$	$V \cdot m^{-1}$
Electric flux	ψ	$\psi = \int D \cdot dA$	C
Electric displacement	D	$D = \varepsilon E$	$C \cdot m^{-2}$
Capacitance	C	$C = Q/U$	$F, C \cdot V^{-1}$
Permittivity	ε	$D = \varepsilon E$	$F \cdot m^{-1}$
Permittivity of vacuum	ε_0	$\varepsilon_0 = \mu_0^{-1} c_0^{-2}$	$F \cdot m^{-1}$
Relative permittivity	ε_r	$\varepsilon_r = \varepsilon/\varepsilon_0$	1
Dielectric polarization (dipole moment per volume)	P	$P = D - \varepsilon_0 E$	$C \cdot m^{-2}$
Electric susceptibility	χ_e	$\chi_e = \varepsilon_\tau - 1$	1
Electric dipole moment	p, μ	$P = Qr$	$C \cdot m$
Electric current	I	$I = dQ/dt$	A
Electric current density	j, J	$I = \int j \cdot dA$	$A \cdot m^{-2}$
Magnetic flux density, magnetic induction	B	$F = Qv \times B$	T
Magnetic flux	Φ	$\Phi = \int B \cdot dA$	Wb
Magnetic field strength	H	$B = \mu H$	$A \cdot M^{-1}$
Permeability	μ	$B = \mu H$	$N \cdot A^{-2}, H \cdot m^{-1}$
Permeability of vacuum	μ_0		$H \cdot m^{-1}$
Relative permeability	μ_t	$\mu_\tau = \mu/\mu_0$	1
Magnetization (magnetic dipole moment per volume)	M	$M = B/\mu_0 - H$	$A \cdot m^{-1}$
Magnetic susceptibility	$\chi, \kappa, (\chi_m)$	$\chi = \mu_\tau - 1$	1
Molar magnetic susceptibility	χ_m	$\chi_m = V_m \chi$	$m^3 \cdot mol^{-1}$
Magnetic dipole moment	m, μ	$E_p = -m \cdot B$	$A \cdot m^2, J \cdot T^{-1}$
Electrical resistance	R	$R = U/I$	Ω
Conductance	G	$G = 1/R$	S
Loss angle	δ	$\delta = (\pi/2) + \phi_I - \phi_U$	1, rad
Reactance	X	$X = (U/I) \sin \delta$	Ω
Impedance (complex impedance)	Z	$Z = R + iX$	Ω
Admittance (complex admittance)	Y	$Y = 1/Z$	S
Susceptance	B	$Y = G + iB$	S
Resistivity	ρ	$\rho = E/j$	$\Omega \cdot m$
Conductivity	κ, γ, σ	$\kappa = 1/\rho$	$S \cdot m^{-1}$
Self-inductance	L	$E = -L(dI/dt)$	H
Mutual inductance	M, L_{12}	$E_1 = L_{12}(dI_2/dt)$	H
Magnetic vector potential	A	$B = \nabla \times A$	$Wb \cdot m^{-1}$
Poynting vector	S	$S = E \times H$	$W \cdot m^{-2}$
		Electromagnetic Radiation	
Wavelength	λ		m
Speed of light			
In vacuum	c_0		$m \cdot s^{-1}$
In a medium	c	$c = c_0/n$	$m \cdot s^{-1}$
Wavenumber in vacuum	$\tilde{\nu}$	$\tilde{\nu} = \nu/c_0 = 1/n\lambda$	m^{-1}
Wavenumber (in a medium)	σ	$\sigma = 1/\lambda$	m^{-1}
Frequency	ν	$\nu = c/\lambda$	Hz
Circular frequency, pulsatance	ω	$\omega = 2\pi\nu$	$s^{-1}, rad \cdot s^{-1}$

Name	Symbol	Definition	SI Unit
Classical Mechanics			
Refractive index	n	$n = c_0/c$	1
Planck constant	h		J · s
Planck constant/2π	$\hbar$	$\hbar = h/2\pi$	J · s
Radiant energy	Q, W		J
Radiant energy density	ρ, w	$\rho = Q/V$	$J \cdot m^{-3}$
Spectral radiant energy density			
In terms of frequency	ρ_ν, w_ν	$\rho_\nu = d\rho/d\nu$	$J \cdot m^{-3} \cdot Hz^{-1}$
In terms of wavenumber	$\rho_{\tilde{v}} w_{\tilde{v}}$	$\rho_\nu = d\rho / d\tilde{v}$	$J \cdot m^{-2}$
In terms of wavelength	ρ_λ, w_λ	$\rho_\lambda = d\rho/d\lambda$	$J \cdot m^{-4}$
Einstein transition probabilities			
Spontaneous emission	A_{nm}	$dN_n/dt = -A_{nm}N_n$	s^{-2}
Stimulated emission	B_{nm}	$dN_n/dt = -\rho_\nu(\tilde{v}_{nm}) \times B_{nm}N_n$	$s \cdot kg^{-1}$
Stimulated absorption	B_{nm}	$dN_n/dt = \rho_{\tilde{v}}(\tilde{v}_{nm}) B_{nm}N_n$	$s \cdot kg^{-1}$
Radiant power, radiant energy per time	Φ, P	$\Phi = dQ/dt$	W
Radiant intensity	I	$I = d\Phi/d\Omega$	$W \cdot sr^{-1}$

Elementary Algebra and Geometry

Fundamental Properties (Real Numbers)

$a + b = b + a$	Commutative law for addition
$(a + b) + c = a + (b + c)$	Associative law for addition
$a + 0 = 0 + a$	Identity law for addition
$a + (-a) = (-a) + a = 0$	Inverse law for addition
$a(bc) = (ab)c$	Associative law for multiplication
$a\left(\frac{1}{a}\right) = \left(\frac{1}{a}\right)a = 1, a \neq 0$	Inverse law for multiplication
$(a)(1) = (1)(a) = a$	Identity law for multiplication
$ab = ba$	Commutative law for multiplication
$a(b + c) = ab + ac$	Distributive law

Division by zero is not defined.

Exponents

For integers m and n,

$$a^n a^m = a^{n+m}$$

$$a^n / a^m = a^{n-m}$$

$$\left(a^n\right)^m = a^{nm}$$

$$(ab)^m = a^m b^m$$

$$(a/b)^m = a^m / b^m$$

Fractional Exponents

$$a^{p/q} = \left(a^{1/q}\right)^p$$

where $a^{1/q}$ is the positive qth root of a if $a > 0$ and the negative qth root of a if a is negative and q is odd. Accordingly, the five rules of exponents given above (for integers) are also valid if m and n are fractions, provided a and b are positive.

Irrational Exponents

If an exponent is irrational (e.g., $\sqrt{2}$), the quantity, such as $a^{\sqrt{2}}$, is the limit of the sequence $a^{1.4}$, $a^{1.41}$, $a^{1.414}$,…

Operations with Zero

$$0^m = 0 \qquad a^0 = 1$$

Logarithms

If x, y, and b are positive $b \neq 1$,

$$\log_b(xy) = \log_b x + \log_b y$$

$$\log_b(x/y) = \log_b x - \log_b y$$

$$\log_b x^p = p \log_b x$$

$$\log_b(1/x) = -\log_b x$$

$$\log_b b = 1$$

$$\log_b 1 = 0 \qquad \textit{Note}: b^{\log_b x} = x$$

Change of Base ($a \neq 1$)

$$\log_b x = \log_a x \log_b a$$

Factorials

The factorial of a positive integer n is the product of all the positive integers less than or equal to the integer n and is denoted $n!$. Thus,

$$n! = 1 \cdot 2 \cdot 3 \cdot \cdots \cdot n$$

Factorial 0 is defined: $0! = 1$.

Stirling's Approximation

$$\lim_{n\to\infty}\left(n/e^n\right)^n \sqrt{2\pi n} = n!$$

Binomial Theorem

For positive integer n

$$\left(x+y\right)^n = x^n + nx^{n-1}y + \frac{n(n-1)}{2!}x^{n-2}y^2 + \frac{n(n-1)(n-2)}{3!}x^{n-3}y^3 + \cdots + nxy^{n-1} + y^n$$

Factors and Expansion

$$(a+b)^2 = a^2 + 2ab + b^2$$

$$(a-b)^2 = a^2 - 2ab + b^2$$

$$(a+b)^3 = a^3 + 3a^2b + 3ab^2 + b^3$$

$$(a-b)^3 = a^3 - 3a^2b + 3ab^2 - b^3$$

$$\left(a^2 - b^2\right) = (a-b)(a+b)$$

$$\left(a^3 - b^3\right) = (a-b)\left(a^2 + ab + b^2\right)$$

$$\left(a^3 + b^3\right) = (a+b)\left(a^2 - ab + b^2\right)$$

Progression

An *arithmetic progression* is a sequence in which the difference between any term and the preceding term is a constant (d):

$$a, a+d, a+2d, \ldots, a+(n-1)d$$

If the last term is denoted l [$= a + (n-1)d$], then the sum is

$$s = \frac{n}{2}(a+l)$$

A *geometric progression* is a sequence in which the ratio of any term to the preceding term is a constant r. Thus, for n terms,

$$a, ar, ar^2, \ldots, ar^{n-1}$$

The sum is

$$S = \frac{a - ar^n}{1 - r}$$

Complex Numbers

A complex number is an ordered pair of real numbers (a, b).

Equality: $(a,b) = (c,d)$ if and only if $a = c$ and $b = d$

Addition: $(a,b) + (c,d) = (a+c, b+d)$

Multiplication: $(a,b)(c,d) = (ac - bd, ad + bc)$

The first element (a, b) is called the *real* part, the second the *imaginary* part. An alternative notation for (a, b) is $a + bi$, where $i^2 = (-1, 0)$, and $i = (0, 1)$ or $0 + 1i$ is written for this complex number as a convenience. With this understanding, i behaves as a number, that is, $(2 - 3i)(4 + i) = 8 + 2i - 12i - 3i^2 = 11 - 10i$. The conjugate of a $a + bi$ is $a - bi$, and the product of a complex number and its conjugate is $a^2 + b^2$. Thus, *quotients* are computed by multiplying numerator and denominator by the conjugate of the denominator, as illustrated below:

$$\frac{2+3i}{4+2i} = \frac{(4-2i)(2+3i)}{(4-2i)(4+2i)} = \frac{14+8i}{20} = \frac{7+4i}{10}$$

Polar Form

The complex number $x + iy$ may be represented by a plane vector with components x and y:

$$x + iy = r(\cos\theta + i\sin\theta)$$

(See Figure 19.1.1.). Then, given two complex numbers $z_1 = \tau_1(\cos\theta_1 + i\sin\theta_1)$ and $z_2 = \tau_2(\cos\theta_2 + i\sin\theta_2)$, the product and quotient are:

Product: $z_1 z_2 = r_1 r_2\left[\cos(\theta_1 + \theta_2) + i\sin(\theta_1 + \theta_2)\right]$

Quotient: $z_1/z_2 = (r_1/r_2)\left[\cos(\theta_1 - \theta_2) + i\sin(\theta_1 - \theta_2)\right]$

Powers: $z^n = \left[r(\cos\theta + i\sin\theta)\right]^n = r^n[\cos n\theta + i\sin n\theta]$

Roots:
$$z^{1/n} = \left[r(\cos\theta + i\sin\theta)\right]^{1/n} = r^{1/n}\left[\cos\frac{\theta + k\cdot 360}{n} + i\sin\frac{\theta + k\cdot 360}{n}\right]$$

$$k = 0, 1, 2, \ldots, n-1$$

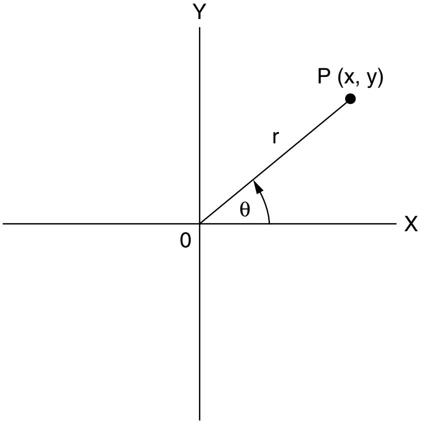

FIGURE 19.1.1 Polar form of complex number.

Permutations

A permutation is an ordered arrangement (sequence) of all or part of a set of objects. The number of permutations of n objects taken r at a time is

$$\begin{aligned} p(n,r) &= n(n-1)(n-2)\cdots(n-r+1) \\ &= \frac{n!}{(n-r)!} \end{aligned}$$

A permutation of positive integers is "even" or "odd" if the total number of inversions is an even integer or an odd integer, respectively. Inversions are counted relative to each integer j in the permutation by counting the number of integers that follow j and are less than j. These are summed to give the total number of inversions. For example, the permutation 4132 has four inversions: three relative to 4 and one relative to 3. This permutation is therefore even.

Combinations

A combination is a selection of one or more objects from among a set of objects regardless of order. The number of combinations of n different objects taken r at a time is

$$C(n,r) = \frac{P(n,r)}{r!} = \frac{n!}{r!(n-r)!}$$

Algebraic Equations

Quadratic

If $ax^2 + bx + c = 0$, and $a \neq 0$, then roots are

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

Cubic

To solve $\mathbf{x}^2 + bx^2 + cx + d = 0$, let $x = y - b/3$. Then the *reduced cubic* is obtained:

$$y^3 + py + q = 0$$

where $p = c - (1/3)b^2$ and $q = d - (1/3)bc + (2/27)b^3$. Solutions of the original cubic are then in terms of the reduced curbic roots y_1, y_2, y_3:

$$x_1 = y_1 - (1/3)b \qquad x_2 = y_2 - (1/3)b \qquad x_3 = y_3 - (1/3)b$$

The three roots of the reduced cubic are

$$y_1 = (A)^{1/3} + (B)^{1/3}$$

$$y_2 = W(A)^{1/3} + W^2(B)^{1/3}$$

$$y_3 = W^2(A)^{1/3} + W(B)^{1/3}$$

where

$$A = -\tfrac{1}{2}q + \sqrt{(1/27)p^3 + \tfrac{1}{4}q^2}$$

$$B = -\tfrac{1}{2}q - \sqrt{(1\ 27)p^3 + \tfrac{1}{4}q^2}$$

$$W = \frac{-1 + i\sqrt{3}}{2}, \qquad W^2 = \frac{-1 - i\sqrt{3}}{2}$$

When $(1/27)p^3 + (1/4)q^2$ is negative, A is complex; in this case A should be expressed in trigonometric form: $A = r(\cos\theta + i\sin\theta)$ where θ is a first or second quadrant angle, as q is negative or positive. The three roots of the reduced cubic are

$$y_1 = 2(r)^{1/3}\cos(\theta/3)$$

$$y_2 = 2(r)^{1/3}\cos\left(\frac{\theta}{3} + 120°\right)$$

$$y_3 = 2(r)^{1/3}\cos\left(\frac{\theta}{3} + 240°\right)$$

Geometry

Figure 19.1.2 to Figure 19.1.12 are a collection of common geometric figures. Area (A), volume (V), and other measurable features are indicated.

Table of Derivatives

In the following table, *a* and *n* are constants, *e* is the base of the natural logarithms, and *u* and *v* denote functions of *x*.

Additional Relations with Derivatives

$$\frac{d}{dt}\int_a^t f(x)\,dx = f(t) \qquad \frac{d}{dt}\int_t^a f(x)\,dx = -f(t)$$

If $x = f(y)$, then $\dfrac{dy}{dx} = \dfrac{1}{dx/dy}$

If $y = f(u)$ and $u = g(x)$, then $\dfrac{dy}{dx} = \dfrac{dy}{du}\cdot\dfrac{du}{dx}$ (chain rule)

If $x = f(t)$ and $y = g(t)$, then $\dfrac{dy}{dx} = \dfrac{g'(t)}{f'(t)}$, and $\dfrac{d^2y}{dx^2} = \dfrac{f'(t)g''(t) - g'(t)f''(t)}{\left[f'(t)\right]^3}$

(Note: Exponent in denominator is 3.)

1. $\dfrac{d}{dx}(a) = 0$

2. $\dfrac{d}{dx}(x) = 1$

3. $\dfrac{d}{dx}(au) = a\dfrac{du}{dx}$

4. $\dfrac{d}{dx}(u+v) = \dfrac{du}{dx} + \dfrac{dv}{dx}$

5. $\dfrac{d}{dx}(uv) = u\dfrac{dv}{dx} + v\dfrac{du}{dx}$

6. $\dfrac{d}{dx}(u/v) = \dfrac{v\dfrac{du}{dx} - u\dfrac{dv}{dx}}{v^2}$

7. $\dfrac{d}{dx}\left(u^n\right) = nu^{n-1}\dfrac{du}{dx}$

8. $\dfrac{d}{dx}e^u = e^u\dfrac{du}{dx}$

9. $\dfrac{d}{dx}a^u = \left(\log_e a\right)a^u\dfrac{du}{dx}$

10. $\dfrac{d}{dx}\log_e u = (1/u)\dfrac{du}{dx}$

11. $\dfrac{d}{dx}\log_a u = \left(\log_a e\right)(1/u)\dfrac{du}{dx}$

12. $\dfrac{d}{dx}u^v = vu^{v-1}\dfrac{du}{dx} + u^v\left(\log_e u\right)\dfrac{dv}{dx}$

13. $\dfrac{d}{dx}\sin u = \cos u\dfrac{du}{dx}$

14. $\dfrac{d}{dx}\cos u = -\sin u\dfrac{du}{dx}$

15. $\dfrac{d}{dx}\tan u = \sec^2 u\dfrac{du}{dx}$

16. $\dfrac{d}{dx}\operatorname{ctn} u = -\csc^2 u\dfrac{du}{dx}$

17. $\dfrac{d}{dx}\sec u = \sec u\tan u\dfrac{du}{dx}$

18. $\dfrac{d}{dx}\csc u = -\csc u\operatorname{ctn} u\dfrac{du}{dx}$

19. $\dfrac{d}{dx}\sin^{-1} u = \dfrac{1}{\sqrt{1-u^2}}\dfrac{du}{dx}, \quad \left(-\tfrac{1}{2}\pi \le \sin^{-1} u \le \tfrac{1}{2}\pi\right)$

20. $\dfrac{d}{dx}\cos^{-1} u = \dfrac{-1}{\sqrt{1-u^2}}\dfrac{du}{dx}, \quad \left(0 \le \cos^{-1} u \le \pi\right)$

21. $\dfrac{d}{dx}\tan^{-1} u = \dfrac{1}{1+u^2}\dfrac{du}{dx}$

22. $\dfrac{d}{dx}\operatorname{ctn}^{-1} u = \dfrac{-1}{1+u^2}\dfrac{du}{dx}$

23. $\dfrac{d}{dx}\sec^{-1} u = \dfrac{1}{u\sqrt{u^2-1}}\dfrac{du}{dx},$

$\left(-\pi \le \sec^{-1} u < -\tfrac{1}{2}\pi;\quad 0 \le \sec^{-1} u \le \tfrac{1}{2}\pi\right)$

24. $\dfrac{d}{dx}\csc^{-1} u = \dfrac{-1}{u\sqrt{u^2-1}}\dfrac{du}{dx},$

$\left(-\pi < \csc^{-1} u \le -\tfrac{1}{2}\pi;\quad 0 < \csc^{-1} u \le \tfrac{1}{2}\pi\right)$

25. $\dfrac{d}{dx}\sinh u = \cosh u\dfrac{du}{dx}$

26. $\dfrac{d}{dx}\cosh u = \sinh u\dfrac{du}{dx}$

27. $\dfrac{d}{dx}\tanh u = \operatorname{sech}^2 u\dfrac{du}{dx}$

28. $\dfrac{d}{dx}\operatorname{ctnh} u = -\operatorname{csch}^2 u\dfrac{du}{dx}$

29. $\dfrac{d}{dx}\operatorname{sech} u = -\operatorname{sech} u\tanh u\dfrac{du}{dx}$

30. $\dfrac{d}{dx}\operatorname{csch} u = -\operatorname{csch} u\operatorname{ctnh} u\dfrac{du}{dx}$

31. $\dfrac{d}{dx}\sin^{-1} u = \dfrac{1}{\sqrt{u^2+1}}\dfrac{du}{dx}$

32. $\dfrac{d}{dx}\cosh^{-1} u = \dfrac{1}{\sqrt{u^2-1}}\dfrac{du}{dx}$

33. $\dfrac{d}{dx}\tanh^{-1} u = \dfrac{1}{1-u^2}\dfrac{du}{dx}$

34. $\dfrac{d}{dx}\operatorname{ctnh}^{-1} u = \dfrac{-1}{u^2-1}\dfrac{du}{dx}$

35. $\dfrac{d}{dx}\operatorname{sech}^{-1} u = \dfrac{-1}{u\sqrt{1-u^2}}\dfrac{du}{dx}$

36. $\dfrac{d}{dx}\operatorname{csch}^{-1} u = \dfrac{-1}{u\sqrt{u^2+1}}\dfrac{du}{dx}$

Integrals

Elementary Forms (Add an arbitrary constant to each integral)

1. $\int a\,dx = ax$

2. $\int a \cdot f(x)\,dx = a\int f(x)\,dx$

3. $\int \phi(y)\,dx = \int \frac{\phi(y)}{y'}\,dy, \quad \text{where } y' = \frac{dy}{dx}$

4. $\int (u+v)\,dx = \int u\,dx + \int v\,dx, \quad \text{where } u \text{ and } v \text{ are any functions of } x$

5. $\int u\,dv = u\int dv - \int v\,du = uv - \int v\,du$

6. $\int u\frac{dv}{dx}\,dx = uv - \int v\frac{du}{dx}\,dx$

7. $\int x^n\,dx = \frac{x^{n+1}}{n+1}, \quad \text{except } n = -1$

8. $\int \frac{f'(x)\,dx}{f(x)} = \log f(x), \quad [df(x) = f'(x)\,dx]$

9. $\int \frac{dx}{x} = \log x$

10. $\int \frac{f'(x)\,dx}{2\sqrt{f(x)}} = \sqrt{f(x)}, \quad [df(x) = f'(x)\,dx]$

11. $\int e^x\,dx = e^x$

12. $\int e^{ax}\,dx = e^{ax}/a$

13. $\int b^{ax}\,dx = \frac{b^{ax}}{a\log b}, \quad (b > 0)$

14. $\int \log x\,dx = x\log x - x$

15. $\int a^x \log a\,dx = a^x, \quad (a > 0)$

16. $\int \frac{dx}{a^2+x^2} = \frac{1}{a}\tan^{-1}\frac{x}{a}$

17. $$\int \frac{dx}{a^2-x^2} = \begin{cases} \frac{1}{a}\tan^{-1}\frac{x}{a} \\ \quad\text{or} \\ \frac{1}{2a}\log\frac{a+x}{a-x}, \quad (a^2 > x^2) \end{cases}$$

18. $$\int \frac{dx}{x^2-a^2} = \begin{cases} -\frac{1}{a}\operatorname{ctnh}^{-1}\frac{x}{a} \\ \quad\text{or} \\ \frac{1}{2a}\log\frac{x-a}{x+a}, \quad (x^2 > a^2) \end{cases}$$

19. $$\int \frac{dx}{\sqrt{a^2 - x^2}} = \begin{cases} \sin^{-1} \dfrac{x}{|a|} \\ \qquad \text{or} \\ -\cos^{-1} \dfrac{x}{|a|}, \quad \left(a^2 > x^2\right) \end{cases}$$

20. $$\int \frac{dx}{\sqrt{x^2 \pm a^2}} = \log\left(x + \sqrt{x^2 \pm a^2}\right)$$

21. $$\int \frac{dx}{x\sqrt{x^2 - a^2}} = \frac{1}{|a|} \sec^{-1} \frac{x}{|a|}$$

22. $$\int \frac{dx}{x\sqrt{a^2 \pm x^2}} = -\frac{1}{a} \log\left(\frac{a + \sqrt{a^2 \pm x^2}}{x}\right)$$

Forms Containing $(a + bx)$

For forms containing $a + bx$, but not listed in the table, the substitution $u = (a + bx)\, x$ may prove helpful.

23. $$\int (a + bx)^n \, dx = \frac{(a + bx)^{n+1}}{(n+1)b}, \quad (n \neq -1)$$

24. $$\int x(a + bx)^n \, dx = \frac{1}{b^2(n+2)}(a + bx)^{n+2} - \frac{a}{b^2(n+1)}(a + bx)^{n+1}, \quad (n \neq -1, -2)$$

25. $$\int x^2(a + bx)^n \, dx = \frac{1}{b^3}\left[\frac{(a + bx)^{n+3}}{n+3} - 2a\frac{(a + bx)^{n+2}}{n+2} + a^2\,\frac{(a + bx)^{n+1}}{n+1}\right]$$

26. $$\int x^m (a + bx)^n \, dx = \begin{cases} \dfrac{x^{m+1}(a + bx)^n}{m+n+1} + \dfrac{an}{m+n+1}\displaystyle\int x^m (a + bx)^{n-1} \, dx \\ \qquad\qquad \text{or} \\ \dfrac{1}{a(n+1)}\left[-x^{m+1}(a + bx)^{n+1} + (m+n+2)\displaystyle\int x^m (a + bx)^{n+1} \, dx\right] \\ \qquad\qquad \text{or} \\ \dfrac{1}{b(m+n+1)}\left[x^m (a + bx)^{n+1} - ma\displaystyle\int x^{m-1}(a + bx)^n \, dx\right] \end{cases}$$

27. $$\int \frac{dx}{a + bx} = \frac{1}{b}\log(a + bx)$$

28. $$\int \frac{dx}{(a + bx)^2} = -\frac{1}{b(a + bx)}$$

29. $$\int \frac{dx}{(a + bx)^3} = -\frac{1}{2b(a + bx)^2}$$

30. $$\int \frac{x\,dx}{a + bx} = \begin{cases} \dfrac{1}{b^2}\left[a + bx - a\log(a + bx)\right] \\ \qquad \text{or} \\ \dfrac{x}{b} - \dfrac{a}{b^2}\log(a + bx) \end{cases}$$

31. $$\int \frac{x\,dx}{(a + bx)^2} = \frac{1}{b^2}\left[\log(a + bx) + \frac{a}{a + bx}\right]$$

32. $\int \frac{x\,dx}{(a+bx)^n} = \frac{1}{b^2}\left[\frac{-1}{(n-2)(a+bx)^{n-2}} + \frac{a}{(n-1)(a+bx)^{n-1}}\right], \quad n \neq 1, 2$

33. $\int \frac{x^2\,dx}{a+bx} = \frac{1}{b^3}\left[\frac{1}{2}(a+bx)^2 - 2a(a+bx) + a^2 \log(a+bx)\right]$

34. $\int \frac{x^2\,dx}{(a+bx)^2} = \frac{1}{b^3}\left[a+bx - 2a\log(a+bx) - \frac{a^2}{a+bx}\right]$

35. $\int \frac{x^2\,dx}{(a+bx)^3} = \frac{1}{b^3}\left[\log(a+bx) + \frac{2a}{a+bx} - \frac{a^2}{2(a+bx)^2}\right]$

36. $\int \frac{x^2\,dx}{(a+bx)^n} = \frac{1}{b^3}\left[\frac{-1}{(n-3)(a+bx)^{n-3}} + \frac{2a}{(n-2)(a+bx)^{n-2}} - \frac{a}{(n-1)(a+bx)^{n-1}}\right], \quad n \neq 1, 2, 3$

37. $\int \frac{dx}{x(a+bx)} = -\frac{1}{a}\log\frac{a+bx}{x}$

38. $\int \frac{dx}{x(a+bx)^2} = \frac{1}{a(a+bx)} - \frac{1}{a^2}\log\frac{a+bx}{x}$

39. $\int \frac{dx}{x(a+bx)^3} = \frac{1}{a^3}\left[\frac{1}{2}\left(\frac{2a+bx}{a+bx}\right)^2 + \log\frac{x}{a+bx}\right]$

40. $\int \frac{dx}{x^2(a+bx)} = -\frac{1}{ax} + \frac{b}{a^2}\log\frac{a+bx}{x}$

41. $\int \frac{dx}{x^3(a+bx)} = \frac{2bx-a}{2a^2x^2} + \frac{b^2}{a^3}\log\frac{x}{a+bx}$

42. $\int \frac{dx}{x^2(a+bx)^2} = -\frac{a+2bx}{a^2x(a+bx)} + \frac{2b^2}{a^3}\log\frac{a+bx}{x}$

The Fourier Transforms

For a piecewise continuous function $F(x)$ over a finite interval $0 \le x \le \pi$, the *finite Fourier cosine transform* of $F(x)$ is

$$f_c(n) = \int_0^{\pi} F(x)\cos nx\,dx \quad (n = 0,\ 1,\ 2,\ \ldots) \tag{19.1.1}$$

If x ranges over the interval $0 \le x \le L$, the substitution $x' = \pi x/L$ allows the use of this definition also. The inverse transform is written

$$\bar{F}(x) = \frac{1}{\pi} f_c(0) + \frac{2}{\pi}\sum_{n=1}^{\infty} f_c(n)\cos nx \quad (0 < x < \pi) \tag{19.1.2}$$

where $\bar{F}(x) = [F(x+0) + F(x-0)]/2$. We observe that $\bar{F}(x) = F(x)$ at points of continuity. The formula

$$\begin{aligned} f_c^{(2)}(n) &= \int_0^{\pi} F''(x)\cos nx\,dx \\ &= -n^2 f_c(n) - F'(0) + (-1)^n F'(\pi) \end{aligned} \tag{19.1.3}$$

makes the finite Fourier cosine transform useful in certain boundary value problems.

Analogously, the *finite Fourier sine transform* of $F(x)$ is

$$f_s(n) = \int_0^\pi F(x)\sin nx\, dx \quad (n = 1,\ 2,\ 3,\ \ldots) \tag{19.1.4}$$

and

$$\bar{F}(x) = \frac{2}{\pi}\sum_{n=1}^{\infty} f_s(n)\sin nx \quad (0 < x < \pi) \tag{19.1.5}$$

Corresponding to Equation (19.1.6), we have

$$\begin{aligned} f_s^{(2)}(n) &= \int_0^\pi F''(x)\sin nx\, dx \\ &= -n^2 f_s(n) - nF(0) - n(-1)^n F(\pi) \end{aligned} \tag{19.1.6}$$

Fourier Transforms

If $F(x)$ is defined for $x \geq 0$ and is piecewise continuous over any finite interval, and if

$$\int_0^\infty F(x)\, dx$$

is absolutely convergent, then

$$f_c(\alpha) = \sqrt{\frac{2}{\pi}}\int_0^\infty F(x)\cos(\alpha x)\, dx \tag{19.1.7}$$

is the *Fourier cosine transform* of $F(x)$. Furthermore,

$$\bar{F}(x) = \sqrt{\frac{2}{\pi}}\int_0^\infty f_c(\alpha)\cos(\alpha x)\, d\alpha \tag{19.1.8}$$

If $\lim_{x\to\infty} d^nF/dx^n = 0$, an important property of the Fourier cosine transform,

$$\begin{aligned} f_c^{(2r)}(\alpha) &= \sqrt{\frac{2}{\pi}}\int_0^\infty \left(\frac{d^{2r}F}{dx^{2r}}\right)\cos(\alpha x)\, dx \\ &= -\sqrt{\frac{2}{\pi}}\sum_{n=0}^{r-1}(-1)^n a_{2r-2n-1}\alpha^{2n} + (-1)^r \alpha^{2r} f_c(\alpha) \end{aligned} \tag{19.1.9}$$

where $\lim_{x\to 0} d^rF/dx^r = a_r$, makes it useful in the solution of many problems.

Under the same conditions,

$$f_s(\alpha) = \sqrt{\frac{2}{\pi}}\int_0^\infty F(x)\sin(\alpha x)\, dx \tag{19.1.10}$$

defines the *Fourier sine transform* of *F(x)*, and

$$\bar{F}(x) = \sqrt{\frac{2}{\pi}} \int_0^\infty f_s(\alpha) \sin(\alpha x)\, d\alpha \tag{19.1.11}$$

Corresponding to Equation (19.1.9) we have

$$\begin{aligned} f_s^{(2r)}(\alpha) &= \sqrt{\frac{2}{\pi}} \int_0^\infty \frac{d^{2r}F}{dx^{2r}} \sin(\alpha x)\, dx \\ &= -\sqrt{\frac{2}{\pi}} \sum_{n=1}^{r} (-1)^n \alpha^{2n-1} a_{2r-2n} + (-1)^{r-1} \alpha^{2r} f_s(\alpha) \end{aligned} \tag{19.1.12}$$

Similarly, if *F(x)* is defined for $-\infty < x < \infty$, and if $\int_{-\infty}^{\infty} F(x)\, dx$ is absolutely convergent, then

$$f(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} F(x) e^{i\alpha x}\, dx \tag{19.1.13}$$

is the *Fourier transform* of *F(x)*, and

$$\bar{F}(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(\alpha) e^{-i\alpha x}\, d\alpha \tag{19.1.14}$$

Also, if

$$\lim_{|x|\to\infty} \left| \frac{d^n F}{dx^n} \right| = 0 \quad (n = 1,\ 2,\ \ldots,\ r-1)$$

then

$$f^{(r)}(\alpha) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} F^{(r)}(x) e^{i\alpha x}\, dx = (-i\alpha)^r f(\alpha) \tag{19.1.15}$$

The following functions appear among the entries of the tables on transforms.

Function	Definition	Name
$\mathrm{Ei}(x)$	$\int_{-\infty}^{x} \frac{e^{v}}{v}\,dv$; or sometimes defined as $-\mathrm{Ei}(-x) = \int_{x}^{\infty} \frac{e^{-v}}{v}\,dv$	Exponential integral function
$\mathrm{Si}(x)$	$\int_{0}^{x} \frac{\sin v}{v}\,dv$	Sine integral function
$\mathrm{Ci}(x)$	$\int_{\infty}^{x} \frac{\cos v}{v}\,dv$; or sometimes defined as negative of this integral	Cosine integral function
$\mathrm{erf}(x)$	$\frac{2}{\sqrt{\pi}} \int_{0}^{x} e^{-v^2}\,dv$	Error function
$\mathrm{erfc}(x)$	$1 - erf(x) = \frac{2}{\sqrt{\pi}} \int_{x}^{\infty} e^{-v^2}\,dv$	Complementary function to error function
$L_n(x)$	$\frac{e^x}{n!} \frac{d^n}{dx^n}\left(x^n e^{-x}\right), \quad n = 0,\ 1,\ \ldots$	Laguerre polynomial of degree n

Bessel Functions

Bessel Functions of the First Kind, J_n(x) (Also Called Simply *Bessel Functions*) (Figure 19.1.13)

Domain: $[x > 0]$
Recurrence relation:

$$J_{n+1}(x) = \frac{2n}{x} J_n(x) - J_{n-1}(x), \quad n = 0,\ 1,\ 2,\ \ldots$$

Symmetry: $J_{-n}(x) = (-1)^n J_n(x)$

0. $J_0(20x)$
1. $J_1(20x)$
2. $J_2(20x)$
3. $J_3(20x)$

8.	$y'' - a^2y = 0$	$y = c_1e^{ax} + c_2e^{-ax}$
9.	$y'' + ay' + by = 0$	Set $y = e^{-(a/2)x}u \rightarrow u'' + \left(b - \frac{a^2}{4}\right)u = 0$
10.	$y'' + a(x)y' + b(x)y = 0$	Set $y = e^{-(1/2)\int a(x)\,dx} \rightarrow u'' + \left[b(x) - \frac{a^2}{4} - \frac{a'}{2}\right]u = 0$
11.	$x^2y'' + xy' + (x^2 - a^2)\,y = 0$ $a \geq 0$ (Bessel)	i. If a is not an integer $y = c_1J_a(x) + c_2J_{-a}(x)$ (Bessel functions of first kind) ii. If a is an integer (say, n) $y = c_1J_n(x) + c_2Y_n(x)$ (Y_n is Bessel function of second kind)
12.	$(1 - x^2)y'' - 2xy' + a(a+1)y = 0$ a is real (Legendre)	$y(x) = c_1p_a(x) + c_1q_a(x)$ (Legendre functions)
13.	$y' + ay^2 = bx^n$ (integrable Riccati) a, b, n real	Set $u' = ayu \rightarrow u'' - abx^nu = 0$ and use 14
14.	$y'' - ax^{-1}y' + b^2x^{\mu}y = 0$	$y = x^p[c_1J_{\nu}(kx^q) + c_2J_{-\nu}(kx^q)$ where $p = (a+1)/2, \nu = (a+1)/(\mu+2)$, $k = 2b/(\mu+2), q = (\mu+2)/2$
15.	Item 13 shows that the Riccati equation is linearized by raising the order of the equation. The *Riccati chain,* which is linearizable by raising the order, is $u' = uy, \quad u'' = u[y^1 + y^2], \quad u''' = u[y'' + 3yy' + y^3],$ $u^{(iv)} = u[y''' + 4yy'' + 6y^2y' + 3(y')^2 + y^4],\ldots$ To use this consider the second-order equation $y'' + 3yy' + y^3 = f(x)$. The Riccati transformation $u' = yu$ transforms this equation to the linear for $u''' = uf(x)$!

19.2 Linear Algebra and Matrices

George Cain

Basic Definitions

A *Matrix* **A** is a rectangular array of numbers (real or complex)

$$\mathbf{A} = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1m} \\ a_{21} & a_{22} & \cdots & a_{2m} \\ \vdots & & & \\ a_{n1} & a_{n2} & \cdots & a_{nm} \end{bmatrix}$$

The *size* of the matrix is said to be $n \times m$. The $1 \times m$ matrices $[a_{i1} \cdots a_{im}]$ are called rows of A, and the $n \times 1$ matrices

$$\begin{bmatrix} a_{1j} \\ a_{2j} \\ \vdots \\ a_{nj} \end{bmatrix}$$

are called *columns* of **A**. An $n \times m$ matrix thus consists of n rows and m columns; a_{ij} denotes the *element,* or *entry,* of **A** in the ith row and jth column. A matrix consisting of just one row is called a *row vector*, whereas a matrix of just one column is called a *column vector.* The elements of a vector are frequently called *components* of the vector. When the size of the matrix is clear from the context, we sometimes write $\mathbf{A} = (a_{ij})$.

A matrix with the same number of rows as columns is a *square* matrix, and the number of rows and columns is the *order* of the matrix. The diagonal of an $n \times n$ square matrix **A** from a_{11} to a_{nn} is called the *main,* or *principal, diagonal.* The word *diagonal* with no modifier usually means the main diagonal. The *transpose* of a matrix **A** is the matrix that results from interchanging the rows and columns of **A**. It is usually denoted by $\mathbf{A}^{\mathrm{T}}$. A matrix **A** such that $\mathbf{A} = \mathbf{A}^{\mathrm{T}}$ is said to be *symmetric.* The *conjugate transpose* of **A** is the matrix that results from replacing each element of $\mathbf{A}^{\mathrm{T}}$ by its complex conjugate, and is usually denoted by $\mathbf{A}^{\mathrm{H}}$. A matrix such that $\mathbf{A} = \mathbf{A}^{\mathrm{H}}$ is said to be *Hermitian.*

A square matrix $\mathbf{A} = (a_{ij})$ is *lower triangular* if $a_{ij} = 0$ for $j > i$ and is *upper triangular* if $a_{ij} = 0$ for $j < i$. A matrix that is both upper and lower triangular is a *diagonal* matrix. The *$n \times n$ identity matrix* is the $n \times n$ diagonal matrix in which each element of the main diagonal is 1. It is traditionally denoted $\mathbf{I}_n$, or simply **I** when the order is clear from the context.

Algebra of Matrices

The sum and difference of two matrices **A** and **B** are defined whenever **A** and **B** have the same size. In that case $\mathbf{C} = \mathbf{A} \pm \mathbf{B}$ is defined by $\mathbf{C} = (c_{ij}) = (a_{ij} \pm b_{ij})$. The product $t\mathbf{A}$ of a scalar t (real or complex number) and a matrix **A** is defined by $t\mathbf{A} = (ta_{ij})$. If **A** is an $n \times m$ matrix and **B** is an $m \times p$ matrix, the product $\mathbf{C} = \mathbf{AB}$ is defined to be the $n \times p$ matrix $\mathbf{C} = (c_{ij})$ given by $c_{ij} = \Sigma_{k=1}^{m} a_{ik}b_{kj}$. Note that the product of an $n \times m$ matrix and an $m \times p$ matrix is an $n \times p$ matrix, and the product is defined only when the number of columns of the first factor is the same as the number of rows of the second factor. Matrix multiplication is, in general, associative: $\mathbf{A}(\mathbf{BC}) = (\mathbf{AB})\mathbf{C}$. It also distributes over addition (and subtraction):

$$\mathbf{A}(\mathbf{B}+\mathbf{C}) = \mathbf{AB}+\mathbf{AC} \quad \text{and} \quad (\mathbf{A}+\mathbf{B})\mathbf{C} = \mathbf{AC}+\mathbf{BC}$$

It is, however, not in general true that $\mathbf{AB} = \mathbf{BA}$, even in case both products are defined. It is clear that $(\mathbf{A} + \mathbf{B})^T = \mathbf{A}^T + \mathbf{B}^T$ and $(\mathbf{A} + \mathbf{B})^H = \mathbf{A}^H + \mathbf{B}^H$. It is also true, but not so obvious perhaps, that $(\mathbf{AB})^T = \mathbf{B}^T\mathbf{A}^T$ and $(\mathbf{AB})^H = \mathbf{B}^H\mathbf{A}^H$.

The $n \times n$ identity matrix $\mathbf{I}$ has the property that $\mathbf{IA} = \mathbf{AI} = \mathbf{A}$ for every $n \times n$ matrix $\mathbf{A}$. If $\mathbf{A}$ is square, and if there is a matrix $\mathbf{B}$ such at $\mathbf{AB} = \mathbf{BA} = \mathbf{I}$, then $\mathbf{B}$ is called the *inverse* of $\mathbf{A}$ and is denoted $\mathbf{A}^{-1}$. This terminology and notation are justified by the fact that a matrix can have at most one inverse. A matrix having an inverse is said to be *invertible,* or *nonsingular,* while a matrix not having an inverse is said to be *noninvertible*, or *singular.* The product of two invertible matrices is invertible and, in fact, $(\mathbf{AB})^{-1} = \mathbf{B}^{-1}\mathbf{A}^{-1}$. The sum of two invertible matrices is, obviously, not necessarily invertible.

Systems of Equations

The system of n linear equations in m unknowns

$$\begin{aligned}
a_{11}x_1 + a_{12}x_2 + a_{13}x_3 + \ldots + a_{1m}x_m &= b_1 \\
a_{21}x_1 + a_{22}x_2 + a_{23}x_3 + \ldots + a_{2m}x_m &= b_2 \\
&\vdots \\
a_{n1}x_1 + a_{n2}x_2 + a_{n3}x_3 + \ldots + a_{nm}x_m &= b_n
\end{aligned}$$

may be written $\mathbf{Ax} = \mathbf{b}$, where $\mathbf{A} = (a_{ij})$, $\mathrm{x} = [\mathrm{x}_1\ \mathrm{x}_2 \cdots \mathrm{x}_m]^T$, and $\mathrm{b} = [\mathrm{b}_1\ \mathrm{b}_2 \cdots \mathrm{b}_n]^T$. Thus A is an $n \times m$ matrix, and x and b are column vectors of the appropriate sizes.

The matrix $\mathbf{A}$ is called the *coefficient matrix* of the system. Let us first suppose the coefficient matrix is square; that is, there are an equal number of equations and unknowns. If $\mathbf{A}$ is upper triangular, it is quite easy to find all solutions of the system. The ith equation will contain only the unknowns $x_i, x_{i+1}, \ldots, x_n$, and one simply solves the equations in reverse order: the last equation is solved for x_n; the result is substituted into the $(n-1)$st equation, which is then solved for x_{n-1}; these values of x_n and x_{n-1} are substituted in the $(n-2)$th equation, which is solved for x_{n-2}, and so on. This procedure is known as *back substitution.*

The strategy for solving an arbitrary system is to find an upper-triangular system equivalent with it and solve this upper-triangular system using back substitution. First suppose the element $a_{11} \neq 0$. We may rearrange the equations to ensure this, unless, of course the first column of $\mathbf{A}$ is all 0s. In this case proceed to the next step, to be described later. For each $i \geq 2$ let $m_{i1} = a_{i1}/a_{11}$. Now replace the ith equation by the result of multiplying the first equation by m_{i1} and subtracting the new equation from the ith equation. Thus,

$$a_{i1}x_1 + a_{i2}x_2 + a_{i3}x_3 + \ldots + a_{im}x_m = b_i$$

is replaced by

$$0 \cdot x_1 + \left(a_{i2} + m_{i1}a_{12}\right)x_2 + \left(a_{i3} + m_{i1}a_{13}\right)x_3 + \ldots + \left(a_{im} + m_{i1}a_{1m}\right)x_m = b_i + m_{i1}b_1$$

After this is done for all $i = 2, 3, \ldots, n$, there results the equivalent system

$$
\begin{aligned}
a_{11}x_1 + a_{12}x_2 + a_{13}x_3 + \ldots + a_{1n}x_n &= b_1 \\
0 \cdot x_1 + a'_{22}x_2 + a'_{23}x_3 + \ldots + a'_{2n}x_n &= b'_2 \\
0 \cdot x_1 + a'_{32}x_2 + a'_{33}x_3 + \ldots + a'_{3n}x_n &= b'_3 \\
&\vdots \\
0 \cdot x_1 + a'_{n2}x_2 + a'_{n3}x_3 + \ldots + a'_{nn}x_n &= b'_n
\end{aligned}
$$

in which all entries in the first column below a_{11} are 0. (Note that if all entries in the first column were 0 to begin with, then $a_{11} = 0$ also.) This procedure is now repeated for the $(n - 1) \times (n - 1)$ system

$$
\begin{aligned}
a'_{22}x_2 + a'_{23}x_3 + \ldots + a'_{2n}x_n &= b'_2 \\
a'_{32}x_2 + a'_{33}x_3 + \ldots + a'_{3n}x_n &= b'_3 \\
&\vdots \\
a'_{n2}x_2 + a'_{n3}x_3 + \ldots + a'_{nn}x_n &= b'_n
\end{aligned}
$$

to obtain an equivalent system in which all entries of the coefficient matrix below a'_{22} are 0. Continuing, we obtain an upper-triangular system Ux = c equivalent with the original system. This procedure is known as *Gaussian elimination*. The number m_{ij} are known as the *multipliers*.

Essentially the same procedure may be used in case the coefficient matrix is not square. If the coefficient matrix is not square, we may make it square by appending either rows or columns of 0s as needed. Appending rows of 0s and appending 0s to make b have the appropriate size equivalent to appending equations 0 = 0 to the system. Clearly the new system has precisely the same solutions as the original system. Appending columns of 0s and adjusting the size of x appropriately yields a new system with additional unknowns, each appearing only with coefficient 0, thus not affecting the solutions of the original system. In either case we may assume the coefficient matrix is square, and apply the Gauss elimination procedure.

Suppose the matrix **A** is invertible. Then if there were no row interchanges in carrying out the above Gauss elimination procedure, we have the *LU factorization* of the matrix **A**:

$$\mathbf{A} = \mathbf{LU}$$

where U is the upper-triangular matrix produced by elimination and L is the lower-triangular matrix given by

$$
\mathbf{L} = \begin{bmatrix} 1 & 0 & \ldots & \ldots & 0 \\ m_{21} & 1 & 0 & \ldots & 0 \\ \vdots & & \ddots & & \\ m_{n1} & m_{n2} & \ldots & & 1 \end{bmatrix}
$$

A *permutation* P_{ij} matrix is an $n \times n$ matrix such that P_{ij} A is the matrix that results from exchanging row *i* and *j* of the matrix A. The matrix P_{ij} is the matrix that results from exchanging rows *i* and *j* of the identity matrix. A product P of such matrices P_{ij} is called a *permutation* matrix. If row interchanges are required in the Gauss elimination procedure, then we have the factorization

$$\mathbf{PA} = \mathbf{LU}$$

where P is the permutation matrix giving the required row exchanges.

Vector Spaces

The collection of all column vectors with n real components is *Euclidean n-space*, and is denoted R^n. The collection of column vectors with n complex components is denoted C^n. We shall use *vector space* to mean either R^n or C^n. In discussing the space R^n, the word *scalar* will mean a real number, and in discussing the space C^n, it will mean a complex number. A subset S of a vector space is a *subspace* such that if $\mathbf{u}$ and $\mathbf{v}$ are vectors in S, and if c is any scalar, then $\mathbf{u} + \mathbf{v}$ and $c\mathbf{u}$ are in S. We shall sometimes use the word *space* to mean a subspace. If $B = \{v_1, v_2, \ldots, v_k\}$ is a collection of vectors in a vector space, then the set S consisting of all vectors $c_1v_1 + c_2v_2 + \cdots + c_mv_m$ for all scalars $c_1, c_2, \ldots, c_m$ is a subspace, called the *span* of B. A collection $\{v_1, v_2, \ldots, v_m\}$ of vectors $c_1v_1 + c_2v_2 + \cdots + c_mv_m$ is a *linear combination* of B. If S is a subspace and $B = \{v_1, v_2, \ldots, v_m\}$ is a subset of S such that S is the span of B, then B is said to *span* S.

A collection $\{v_1, v_2, \ldots, v_m\}$ of n-vectors is *linearly dependent* if there exist scalars $c_1, c_2, \ldots, c_m$, not all zero, such that $c_1v_1 + c_2v_2 + \cdots + c_mv_m = 0$. A collection of vectors that is not linearly dependent is said to be *linearly independent*. The modifier *linearly* is frequently omitted, and we speak simply of dependent and independent collections. A linearly independent collection of vectors in a space S that spans S is a *basis* of S. Every basis of a space S contains the same number of vectors; this number is the *dimension* of S. The dimension of the space consisting of only the zero vector is 0. The collection $B = \{e_1, e_2, \ldots, e_n\}$, where $e_1 = [1,0,0,\ldots, 0]^T$, $e_2 = [0,1,0,\ldots, 0]^T$, and so forth ($e_i$ has 1 as its ith component and zero for all other components) is a basis for the spaces R^n and C^n. This is the *standard basis* for these spaces. The dimension of these spaces is thus n. In a space S of dimension n, no collection of fewer than n vectors can span S, and no collection of more than n vectors in S can be independent.

Rank and Nullity

The *column space* of an $n \times m$ matrix $\mathbf{A}$ is the subspace of R^n or C^n spanned by the columns of $\mathbf{A}$. The *row space* is the subspace of R^m or C^m spanned by the rows or $\mathbf{A}$. Note that for any vector $x = [x_1\ x_2, \cdots x_m]^T$,

$$\mathbf{Ax} = x_1 \begin{bmatrix} a_{11} \\ a_{21} \\ \vdots \\ a_{n1} \end{bmatrix} + x_2 \begin{bmatrix} a_{12} \\ a_{22} \\ \vdots \\ a_{n2} \end{bmatrix} + \ldots + x_m \begin{bmatrix} a_{1m} \\ a_{2m} \\ \vdots \\ a_{nm} \end{bmatrix}$$

so that the column space is the collection of all vectors, $\mathbf{Ax}$, and thus the system $\mathbf{Ax} = \mathbf{b}$ has a solution if and only *if* $\mathbf{b}$ is a member of the column space of $\mathbf{A}$.

The dimension of the column space is the *rank* of $\mathbf{A}$. The row space has the same dimension as the column space. The set of all solutions of the system $\mathbf{Ax} = 0$ is a subspace called the *null space* of $\mathbf{A}$, and the dimension of this null space is the *nullity* of $\mathbf{A}$. A fundamental result in matrix theory is the fact that, for an $n \times m$ matrix $\mathbf{A}$.

$$\text{rank } \mathbf{A} + \text{nullity } \mathbf{A} = m$$

The difference of any two solutions of the linear system $\mathbf{Ax} = \mathbf{b}$ is a member of the null space of $\mathbf{A}$. Thus this system has at most one solution if and only if the nullity of $\mathbf{A}$ is zero. If the system is square (that is, if $\mathbf{A}$ is $n \times n$), then there will be a solution for every right-hand side $\mathbf{b}$ if and only if the collection of columns of $\mathbf{A}$ is linearly independent, which is the same as saying the rank of $\mathbf{A}$ is n. In this case the nullity must be zero. Thus, for any $\mathbf{b}$, the square system $\mathbf{Ax} = \mathbf{b}$ has exactly one solution if and only if rank $\mathbf{A} = n$. In other words the $n \times n$ matrix $\mathbf{A}$ is invertible if and only if rank $\mathbf{A} = n$.

Orthogonality and Length

The *inner product* of two vectors x and y is the scalar x^Hy. The *length*, or *norm*, $\|x\|$, of the vector $\mathbf{x}$ is given by $\|x\| = \sqrt{\mathbf{x}^H\mathbf{x}}$. A *unit vector* is a vector of norm 1. Two vectors x and y are *orthogonal* if $x^Hy = 0$.

A collection of vectors $\{v_1, v_2, \ldots, v_m\}$ in a space S is said to be an *orthonormal* collection if $\mathbf{v}_i^H \mathbf{v}_j = 0$ for $i \neq j$ and $\mathbf{v}_i^H \mathbf{v}_i = 1$. An orthonormal collection is necessarily linearly independent. If S is a subspace (of R^n or C^n) spanned by the orthonormal collection $\{v_1, v_2, \ldots, v_m\}$, then the *projection* of a vector x onto S is the vector

$$\text{proj}(\mathbf{x}; \mathbf{S}) = (\mathbf{x}^H \mathbf{v}_1)\mathbf{v}_1 + (\mathbf{x}^H \mathbf{v}_2)\mathbf{v}_2 + \ldots + (\mathbf{x}^H \mathbf{v}_m)\mathbf{v}_m$$

The projection of x onto S minimizes the function $f(y) = \|x - y\|^2$ for $y \in S$. In other words the projection of x onto S is the vector in S that is "closest" to x.

If **b** is a vector and **A** is an $n \times m$ matrix, then a vector x minimizes $\|b - Ax\|^2$ if only if it is a solution of $A^H Ax = A^H b$. This system of equations is called the *system of normal equations* for the least-squares problem of minimizing $\|b - Ax\|^2$.

If **A** is an $n \times m$ matrix, and rank $\mathbf{A} = k$, then there is a $n \times k$ matrix Q whose columns form an orthonormal basis for the column space of **A** and a $k \times m$ upper-triangular matrix **R** of rank k such that

$$\mathbf{A} = \mathbf{QR}$$

This is called the *QR factorization* of **A**. It now follows that x minimizes $\|b - Ax\|^2$ if and only if it is a solution of the upper-triangular system $Rx = Q^H b$.

If $\{w_1, w_2, \ldots, w_m\}$ is a basis for a space S, the following procedure produces an orthonormal basis $\{v_1, v_2, \ldots, v_m\}$ for S.

Set $\mathbf{v}_1 = \mathbf{w}_1 / \|\mathbf{w}_1\|$.
Let $\tilde{\mathbf{v}}_2 = \mathbf{w}_2 - \text{proj}(\mathbf{w}_2; \mathbf{S}_1)$, where $\mathbf{S}_1$ is the span of $\{\mathbf{v}_1\}$; set $\mathbf{v}_2 = \tilde{\mathbf{v}}_2 / \|\tilde{\mathbf{v}}_2\|$.
Next, let $\tilde{\mathbf{v}}_3 = \mathbf{w}_3 - \text{proj}(\mathbf{w}_3; \mathbf{S}_2)$, where $\mathbf{S}_2$ is the span of $\{\mathbf{v}_1, v_2\}$; set $\mathbf{v}_3 = \tilde{\mathbf{v}}_3 / \|\tilde{\mathbf{v}}_3\|$.

And, so on: $\tilde{\mathbf{v}}_i = w_i - \text{proj}(w_i; S_{i-1})$, where S_{i-1} is the span of $\{v_1, v_2, \ldots, v_{i-1}\}$; set $v_i = \tilde{\mathbf{v}}_i / \|\tilde{\mathbf{v}}_i\|$. This the *Gram-Schmidt procedure.*

If the collection of columns of a square matrix is an orthonormal collection, the matrix is called a *unitary matrix*. In case the matrix is a real matrix, it is usually called an *orthogonal matrix*. A unitary matrix U is invertible, and $\mathbf{U}^{-1} = \mathbf{U}^H$. (In the real case an orthogonal matrix **Q** is invertible, and $\mathbf{Q}^{-1} = \mathbf{Q}^T$.)

Determinants

The *determinant* of a square matrix is defined inductively. First, suppose the determinant det **A** has been defined for all square matrices of order $< n$. Then

$$\det \mathbf{A} = a_{11}\mathbf{C}_{11} + a_{12}\mathbf{C}_{12} + \ldots + a_{1n}\mathbf{C}_{1n}$$

where the numbers C_{ij} are *cofactors* of the matrix **A**:

$$\mathbf{C}_{ij} = (-1)^{i+j} \det \mathbf{M}_{ij}$$

where M_{ij} is the $(n - 1) \times (n - 1)$ matrix obtained by deleting the ith row and jth column of **A**. Now det**A** is defined to be the only entry of a matrix of order 1. Thus, for a matrix of order 2, we have

$$\det \begin{bmatrix} a & b \\ c & d \end{bmatrix} = ad - bc$$

There are many interesting but not obvious properties of determinants. It is true that

$$\det\mathbf{A} = a_{i1}\mathbf{C}_{i1} + a_{i2}\mathbf{C}_{i2} + \ldots + a_{in}\mathbf{C}_{in}$$

for any $1 \le i \le n$. It is also true that det**A** = det$\mathbf{A}^T$, so that we have

$$\det\mathbf{A} = a_{1j}\mathbf{C}_{1j} + a_{2j}\mathbf{C}_{2j} + \ldots + a_{nj}\mathbf{C}_{nj}$$

for any $1 \le j \le n$.

If **A** and **B** are matrices of the same order, then det**AB** = (det**A**)(det**B**), and the determinant of any identity matrix is 1. Perhaps the most important property of the determinant is the fact that a matrix in invertible if and only if its determinant is not zero.

Eigenvalues and Eigenvectors

If **A** is a square matrix, and **Av** = λv for a scalar λ and a nonzero v, then λ is an *eigenvalue* of **A** and v is an *eigenvector* of **A** that *corresponds* to λ. Any nonzero linear combination of eigenvectors corresponding to the same eigenvalue λ is also an eigenvector corresponding to λ. The collection of all eigenvectors corresponding to a given eigenvalue λ is thus a subspace, called an *eigenspace* of **A**. A collection of eigenvectors corresponding to different eigenvalues is necessarily linear-independent. It follows that a matrix of order n can have at most n distinct eigenvectors. In fact, the eigenvalues of **A** are the roots of the nth degree polynomial equation

$$\det(\mathbf{A} - \lambda\mathbf{I}) = 0$$

called the *characteristic equation* of **A**. (Eigenvalues and eigenvectors are frequently called *characteristic values* and *characteristic vectors.*)

If the nth order matrix **A** has an independent collection of n eigenvectors, then **A** is said to have a *full set* of eigenvectors. In this case there is a set of eigenvectors of **A** that is a basis for R^n or, in the complex case, C^n. In case there are n distinct eigenvalues of **A**, then, of course, **A** has a full set of eigenvectors. If there are fewer than n distinct eigenvalues, then **A** may or may not have a full set of eigenvectors. If there is a full set of eigenvectors, then

$$\mathbf{D} = \mathbf{S}^{-1}\mathbf{A}\mathbf{S} \quad \text{or} \quad \mathbf{A} = \mathbf{S}\mathbf{D}\mathbf{S}^{-1}$$

where **D** is a diagonal matrix with the eigenvalues of **A** on the diagonal, and **S** is a matrix whose columns are the full set of eigenvectors. If **A** is symmetric, there are n real distinct eigenvalues of **A** and the corresponding eigenvectors are orthogonal. There is thus an orthonormal collection of eigenvectors that span R^n, and we have

$$\mathbf{A} = \mathbf{Q}\mathbf{D}\mathbf{Q}^T \quad \text{and} \quad \mathbf{D} = \mathbf{Q}^T\mathbf{A}\mathbf{Q}$$

where **Q** is a real orthogonal matrix and **D** is diagonal. For the complex case, if **A** is Hermitian, we have

$$\mathbf{A} = \mathbf{U}\mathbf{D}\mathbf{U}^H \quad \text{and} \quad \mathbf{D} = \mathbf{U}^H\mathbf{A}\mathbf{U}$$

where **U** is a unitary matrix and **D** is a *real* diagonal matrix. (A Hermitian matrix also has n distinct real eigenvalues.)

19.3 Vector Algebra and Calculus

George Cain

Basic Definitions

A vector is a directed line segment, with two vectors being equal if they have the same length and the same direction. More precisely, a *vector* is an equivalence class of directed line segments, where two directed segments are equivalent if they have the same length and the same direction. The *length* of a vector is the common length of its directed segments, and the *angle between* vectors is the angle between any of their segments. The length of a vector u is denoted $|\mathbf{u}|$. There is defined a distinguished vector having zero length, which is usually denoted **0**. It is frequently useful to visualize a directed segment as an arrow; we then speak of the nose and the tail of the segment. The *sum* $\mathbf{u} + \mathbf{v}$ of two vectors **u** and **v** is defined by taking directed segments from **u** and **v** and placing the tail of the segment representing **v** at the nose of the segment representing **u** and defining $\mathbf{u} + \mathbf{v}$ to be the vector determined by the segment from the tail of the **u** representative to the nose of the **v** representative. It is easy to see that $\mathbf{u} + \mathbf{v}$ is well defined and that $\mathbf{u} + \mathbf{v} = \mathbf{v} + \mathbf{u}$. Subtraction is the inverse operation of addition. Thus the *difference* $\mathbf{u} - \mathbf{v}$ of two vectors is defined to be the vector that when added to **v** gives **u**. In other words, if we take a segment from **u** and a segment from **v** and place their tails together, the difference is the segment from the nose of v to the nose of **u**. The zero vector behaves as one might expect; $\mathbf{u} + \mathbf{0} = \mathbf{u}$, and $\mathbf{u} - \mathbf{u} = \mathbf{0}$. Addition is associative: $\mathbf{u} + (\mathbf{v} + \mathbf{w}) = (\mathbf{u} + \mathbf{v}) + \mathbf{w}$.

To distinguish them from vectors, the real numbers are called *scalars*. The product $t\mathbf{u}$ of a scalar t and a vector **u** is defined to be the vector having length $|t|\ |\mathbf{u}|$ and direction the same as **u** if $t > 0$, the opposite direction if $t < 0$, If $t = 0$, then $t\mathbf{u}$ is defined to be the zero vector. Note that $t(\mathbf{u} + \mathbf{v}) = t\mathbf{u} + t\mathbf{v}$, and $(t + s)\mathbf{u} = t\mathbf{u} + s\mathbf{u}$. From this it follows that $\mathbf{u} - \mathbf{v} = \mathbf{u} + (-1)\mathbf{v}$.

The *scalar product* $\mathbf{u} \cdot \mathbf{v}$ of two vectors is $|\mathbf{u}||\mathbf{v}| \cos \boldsymbol{\theta}$, where θ is the angle between **u** and **v**. The scalar product is frequently called the *dot product.* The scalar product distributes over addition:

$$\mathbf{u} \cdot (\mathbf{v} + \mathbf{w}) = \mathbf{u} \cdot \mathbf{v} + \mathbf{u} \cdot \mathbf{w}$$

and it is clear that $(t\mathbf{u}) \cdot \mathbf{v} = t(\mathbf{u} \cdot \mathbf{v})$. The *vector product* $\mathbf{u} \times \mathbf{v}$ of two vectors is defined to be the vector perpendicular to both **u** and **v** and having length $\mathbf{u}||\mathbf{v}| \sin \theta$, where θ is the angle between **u** and **v**. The direction of $\mathbf{u} \times \mathbf{v}$ is the direction a right-hand threaded bolt advances if the vector **u** is rotated to **v**. The vector is frequently called the *cross product.* The vector product is both associative and distributive, but not commutative: $\mathbf{u} \times \mathbf{v} = -\mathbf{v} \times \mathbf{u}$.

Coordinate Systems

Suppose we have a right-handed Cartesian coordinate system in space. For each vector, **u**, we associate a point in space by placing the tail of a representative of **u** at the origin and associating with **u** the point at the nose of the segment. Conversely, associated with each point in space is the vector determined by the directed segment from the origin to that point. There is thus a one-to-one correspondence between the points in space and all vectors. The origin corresponds to the zero vector. The coordinates of the point associated with a vector **u** are called *coordinates* of **u**. One frequently refers to the vector **u** and writes $\mathbf{u} = (x, y, z)$, which is, strictly speaking, incorrect, because the left side of this equation is a vector and the right side gives the coordinates of a point in space. What is meant is that (x, y, z) are the coordinates of the point associated with **u** under the correspondence described. In terms of coordinates, for $\mathbf{u} = (u_1, u_2, u_3)$ and $\mathbf{v} = (v_1, v_2, v_3)$, we have

$$\mathbf{u} + \mathbf{v} = (u_1 + v_1, u_2 + v_2, u_3 + v_3)$$

$$t\mathbf{u} = (tu_1, tu_2, tu_3)$$

$$\mathbf{u}\cdot\mathbf{v} = u_1v_1 + u_2v_2 + u_3v_3$$

$$\mathbf{u}\times\mathbf{v} = \left(u_2v_3 - v_2u_3,\ u_3v_1 - v_3u_1,\ u_1v_2 - v_1u_2\right)$$

The *coordinate vectors* **i**, **j**, and **k** are the unit vectors i = (1, 0, 0), j = (0, 1, 0), and k = (0, 0, 1). Any vector **u** = (u_1, u_2, u_3) is thus a linear combination of these coordinate vectors: u = u_1i + u_2j + u_3k. A convenient form for the vector product is the formal determinant

$$\mathbf{u}\times\mathbf{v} = \det\begin{bmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ u_1 & u_2 & u_3 \\ v_1 & v_2 & v_2 \end{bmatrix}$$

Vector Functions

A *vector function* **F** *of one variable* is a rule that associates a vector **F**(t) with each real number t in some set, called the *domain* of **F**. The expression $\lim_{t\to t_0} \mathbf{F}(t) = \mathbf{a}$ means that for any $\varepsilon > 0$, there is a $\delta > 0$ such that $|\mathbf{F}(t) - \mathbf{a}| < \varepsilon$ whenever $0 < |t - t_0| < \delta$. If $\mathbf{F}(t) = [x(t), y(t), z(t)]$ and $\mathbf{a} = (a_1, a_2, a_3)$, then $\lim_{t\to t_0} \mathbf{F}(t) = \mathbf{a}$ if and only if

$$\lim_{t\to t_0} x(t) = a_1$$

$$\lim_{t\to t_0} y(t) = a_2$$

$$\lim_{t\to t_0} z(t) = a_3$$

A vector function **F** is *continuous* at t_0 if $\lim_{t\to t_0} \mathbf{F}(t) = \mathbf{F}(t_0)$. The vector function **F** is continuous at t_0 if and only if each of the coordinates $x(t)$, $y(t)$, and $z(t)$ is continuous at t_0.

The function **F** is *differentiable* at t_0 if the limit

$$\lim_{h\to 0}\frac{1}{h}\left[\mathbf{F}(t+h) - \mathbf{F}(t)\right]$$

exists. This limit is called the *derivative* of **F** at t_0 and is usually written $\mathbf{F}'(t_0)$, or $(d\mathbf{F}/dt)(t_0)$. The vector function **F** is differentiable at t_0 if and only if each of its coordinate functions is differentiable at t_0. Moreover, $(d\mathbf{F}/dt)(t_0) = [(dx/dt)(t_0), (dy/dt)(t_0), (dz/dt)(t_0)]$. The usual rules for derivatives of real valued functions all hold for vector functions. Thus if **F** and **G** are vector functions and s is a scalar function, then

$$\frac{d}{dt}(\mathbf{F}+\mathbf{G}) = \frac{d\mathbf{F}}{dt} + \frac{d\mathbf{G}}{dt}$$

$$\frac{d}{dt}(s\mathbf{F}) = s\frac{d\mathbf{F}}{dt} + \frac{ds}{dt}\mathbf{F}$$

$$\frac{d}{dt}(\mathbf{F}\cdot\mathbf{G}) = \mathbf{F}\cdot\frac{d\mathbf{G}}{dt} + \frac{d\mathbf{F}}{dt}\cdot\mathbf{G}$$

$$\frac{d}{dt}(\mathbf{F}\times\mathbf{G}) = \mathbf{F}\times\frac{d\mathbf{G}}{dt} + \frac{d\mathbf{F}}{dt}\times\mathbf{G}$$

If **R** is a vector function defined for t in some interval, then, as t varies, with the tail of **R** at the origin, the nose traces out some object C in space. For nice functions **R**, the object C is a *curve*. If $\mathbf{R}(t) = [x(t), y(t), z(t)]$, then the equations

$$x = x(t)$$

$$y = y(t)$$

$$z = z(t)$$

are called *parametric equations* of C. At points where **R** is differentiable, the derivative $d\mathbf{R}/dt$ is a vector *tangent* to the curve. The unit vector $\mathbf{T} = (d\mathbf{R}/dt)/|d\mathbf{R}/dt|$ is called the *unit tangent vector*. If **R** is differentiable and if the length of the arc of curve described by **R** between $\mathbf{R}(a)$ and $\mathbf{R}(t)$ is given by $s(t)$, then

$$\frac{ds}{dt} = \left|\frac{d\mathbf{R}}{dt}\right|$$

Thus the length L of the arc from $\mathbf{R}(t_0)$ to $\mathbf{R}(t_1)$ is

$$L = \int_{t_0}^{t_1} \frac{ds}{dt}\,dt = \int_{t_0}^{t_1} \left|\frac{d\mathbf{R}}{dt}\right| dt$$

The vector $d\mathbf{T}/ds = (d\mathbf{T}/dt)/(ds/dt)$ is perpendicular to the unit tangent **T**, and the number $\kappa = |d\mathbf{T}/ds|$ is the *curvature* of C. The unit vector $\mathbf{N} = (1/\kappa)(d\mathbf{T}/ds)$ is the *principal normal*. The vector $\mathbf{B} = \mathbf{T} \times \mathbf{N}$ is the *binormal*, and $d\mathbf{B}/ds = -\tau N$. The number τ is the *torsion*. Note that C is a plane curve if and only if τ is zero for all t.

A *vector function* **F** *of two variables* is a rule that assigns a vector $\mathbf{F}(s, t)$ in some subset of the plane, called the *domain* of **F**. If $\mathbf{R}(s, t)$ is defined for all (s, t) in some region D of the plane, then as the point (s, t) varies over D, with its rail at the origin, the nose of $\mathbf{R}(s, t)$ traces out an object in space. For a nice function **R**, this object is a *surface*, S. The partial derivatives $(\partial\mathbf{R}/\partial s)(s, t)$ and $(\partial\mathbf{R}/\partial t)(s, t)$ are tangent to the surface at $\mathbf{R}(s, t)$, and the vector $(\partial\mathbf{R}/\partial s) \times (\partial\mathbf{R}/\partial t)$ is thus *normal* to the surface. Of course, $(\partial\mathbf{R}/\partial t) \times (\partial\mathbf{R}/\partial s) = -(\partial\mathbf{R}/\partial s) \times (\partial\mathbf{R}/\partial t)$ is also normal to the surface and points in the direction opposite that of $(\partial\mathbf{R}/\partial s) \times (\partial\mathbf{R}/\partial t)$. By electing one of these normal, we are choosing an *orientation* of the surface. A surface can be oriented only if it has two sides, and the process of orientation consists of choosing which side is "positive" and which is "negative."

Gradient, Curl, and Divergence

If $f(x, y, z)$ is a scalar field defined in some region D, the *gradient* of **f** is the vector function

$$\operatorname{grad} f = \frac{\partial f}{\partial x}\mathbf{i} + \frac{\partial f}{\partial y}\mathbf{j} + \frac{\partial f}{\partial z}\mathbf{k}$$

If $\mathbf{F}(x, y, z) = F_1(x, y, z)\mathbf{i} + F_2(x, y, z)\mathbf{j} + F_3(x, y, z)\mathbf{k}$ is a vector field defined in some region D, then the *divergence* of **F** is the scalar function

$$\operatorname{div} \mathbf{F} = \frac{\partial F_1}{\partial x} + \frac{\partial F_2}{\partial y} + \frac{\partial F_3}{\partial z}$$

The curl is the vector function

$$\operatorname{curl}\mathbf{F} = \left(\frac{\partial F_3}{\partial y} - \frac{\partial F_2}{\partial z}\right)\mathbf{i} + \left(\frac{\partial F_1}{\partial z} - \frac{\partial F_3}{\partial x}\right)\mathbf{j} + \left(\frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y}\right)\mathbf{k}$$

In terms of the vector operator *del*, $\nabla = \mathbf{i}(\partial/\partial x) + \mathbf{j}(\partial/\partial y) + \mathbf{k}(\partial/\partial z)$, we can write

$$\operatorname{grad} f = \nabla f$$

$$\operatorname{div}\mathbf{F} = \nabla \cdot \mathbf{F}$$

$$\operatorname{curl}\mathbf{F} = \nabla \times \mathbf{F}$$

The *Laplacian operator* is div (grad) $= \nabla \cdot \nabla = \nabla^2 = (\partial^2/\partial x^2) + (\partial^2/\partial y^2) + (\partial^2/\partial z^2)$.

Integration

Suppose C is a curve from the point (x_0, y_0, z_0) to the point (x_1, y_1, z_1) and is described by the vector function $\mathbf{R}(t)$ for $t_0 \le t \le t_1$. If f f is a scalar function (sometimes called a *scalar field*) defined on C, then the integral of f over C is

$$\int_C f(x,y,z)\, ds = \int_{t_0}^{t_1} f[\mathbf{R}(t)] \left|\frac{d\mathbf{R}}{dt}\right| dt$$

If $\mathbf{F}$ is a vector function (sometimes called a *vector field*) defined on C, then the integral of $\mathbf{F}$ over C is

$$\int_C \mathbf{F}(x,y,z) \cdot d\mathbf{R} = \int_{t_0}^{t_1} \mathbf{F}[\mathbf{R}(t)] \frac{d\mathbf{R}}{dt}\, dt$$

These integrals are called *line integrals.*

In case there is a scalar function f such that $\mathbf{F} = \operatorname{grad} f$, then the line integral

$$\int_C \mathbf{F}(x,y,z) \cdot d\mathbf{R} = f[\mathbf{R}(t_1)] - f[\mathbf{R}(t_0)]$$

The value of the integral thus depends only on the end points of the curve C and not on the curve C itself. The integral is said to be *path-independent.* The function f is called a *potential function* for the vector field $\mathbf{F}$, and $\mathbf{F}$ is said to be a *conservative field.* A vector field $\mathbf{F}$ with domain D is conservative if and only if the integral of $\mathbf{F}$ around every closed curve in D is zero. If the domain D is simply connected (that is, every closed curve in D can be continuously deformed in D to a point), then $\mathbf{F}$ is conservative if and only if curl $\mathbf{F} = 0$ in D.

Suppose S is a surface described by $\mathbf{R}(s, t)$ for (s, t) in a region D of the plane. If f is a scalar function defined on D, then the integral of f over S is given by

$$\int\!\!\int_S f(x,y,z)\, dS = \int\!\!\int_D f[\mathbf{R}(s,t)] \left|\frac{\partial \mathbf{R}}{\partial s} \times \frac{\partial \mathbf{R}}{\partial t}\right| ds\, dt$$

If $\mathbf{F}$ is a vector function defined on S, and if an orientation for S is chosen, then the integral $\mathbf{F}$ over S, sometimes called the flux of $\mathbf{F}$ through S, is

$$\int\!\!\int_S \mathbf{F}(x,y,z) \cdot d\mathbf{S} = \int\!\!\int_D \mathbf{F}[\mathbf{R}(s,t)] \left|\frac{\partial \mathbf{R}}{\partial s} \times \frac{\partial \mathbf{R}}{\partial t}\right| ds\, dt$$

Integral Theorems

Suppose **F** is a vector field with a closed domain D bounded by the surface S oriented so that the normal points out from D. Then the *divergence theorem* states that

$$\iiint_D \operatorname{div} \mathbf{F}\, dV = \iint_S \mathbf{F} \cdot \mathbf{dS}$$

If S is an orientable surface bounded by a closed curve C, the orientation of the closed curve C is chosen to be consistent with the orientation of the surface S. Then we have *Stoke's theorem:*

$$\iint_S (\text{curl } \mathbf{F}) \cdot d\mathbf{S} = \oint_C \mathbf{F} \cdot \mathbf{ds}$$

19.4 Difference Equations

William F. Ames

Difference equations are equations involving *discrete variables.* They appear as natural descriptions of natural phenomena and in the study of discretization methods for differential equations, which have continuous variables.

Let $y_n = y(nh)$, where n is an integer and h is a real number. (One can think of measurements taken at equal intervals, h, $2h$, $3h$, …, and y_n describes these). A typical equation is that describing the famous Fibonacci sequence — $y_{n+2} - y_{n+1} - y_n = 0$. Another example is the equation $y_{n+2} - 2zy_{n+1} + y_n = 0$, $z \in C$, which describes the Chebyshev polynomials.

First-Order Equations

The general first-order equation $y_{n+1} = f(y_n)$, $y_0 = y(0)$ is easily solved, for as many terms as are needed, by *iteration.* Then $y_1 = f(y_0)$; $y_2 = f(y_1)$,…. An example is the logistic equation $y_{n+1} = ay_n(1 - y_n) = f(y_n)$. The logistic equation has two fixed (critical or equilibrium) points where $y_{n+1} = y_n$. They are 0 and $\bar{y} = (a - 1)/a$. This has physical meaning only for $a > 1$. For $1 < a < 3$ the equilibrium $\bar{y}$ is asymptotically stable, and for $a > 3$ there are two points y_1 and y_2, called a *cycle of period two*, in which $y_2 = f(y_1)$ and $y_1 = f(y_2)$. This study leads into chaos, which is outside our interest. By iteration, with $y_0 = {}^1\!/_2$, we have $y_1 = (a/2)(1/2) = a/2^2$, $y_2 = a(a/2^2)(1 - a/2^2) = (a^2/2^2)(1 - a/2^2)$, ….

With a constant, the equation $y_{n+1} = ay_n$ is solved by making the assumption $y_n = A\lambda^n$ and finding λ so that the equation holds. Thus $A\lambda^{n+1} = aA\lambda^n$, and hence $\lambda = 0$ or $\lambda = a$ and A is arbitrary. Discarding the trivial solution 0 we find $y_n = Aa^{n+1}$ is the desired solution. By using a method called the *variation of constants,* the equation $y_{n+1} - ay_n = g_n$ has the solution $y_n = y_0a^n + \Sigma_{j=0}^{n-1} g_j a^{n-j-1}$, with y_0 arbitrary.

In various applications we find the first-order equation of *Riccati type* $y_ny_{n-1} + ay_n + by_{n-1} + c = 0$ where a, b, and c are real constants. This equation can be transformed to a linear second-order equation by setting $y_n = z_n/z_{n-1} - a$ to obtain $z_{n+1} + (b + a)z_n + (c - ab)z_{n-1} = 0$, which is solvable as described in the next section.

Second-Order Equations

The second-order linear equation with constant coefficients $y_{n+2} + ay_{n+1} + by_n = f_n$ is solved by first solving the homogeneous equation (with right-hand side zero) and adding to that solution any solution of the inhomogeneous equation. The *homogeneous equation* $y_{n+2} + ay_{n+1}\ by_n = 0$ is solved by assuming $y_n = \lambda^n$, whereupon $\lambda^{n+2} + a\lambda^{n+1} + b\lambda^n = 0$ or $\lambda = 0$ (rejected) or $\lambda^2 + a\lambda + b = 0$. The roots of this quadratic are $\lambda_1 = {}^1/_2\,(-a + \sqrt{a^2 - 4b})$, $\lambda_2 = -{}^1/_2\,(a + \sqrt{a^2 - 4b})$ and the solution of the homogeneous equation is $y_n = c_1\lambda_1^n + c_2\lambda_2^n$. As an example consider the Fibonacci equation $y_{n+2} - y_{n+1} - y_n = 0$. The roots of $\lambda^2 - \lambda - 1 = 0$ are $\lambda_1 = {}^1/_2\,(1 + \sqrt{5})$, $\lambda_2 = {}^1/_2\,(1 - \sqrt{5})$, and the solution $y_n = c_1[(1 + \sqrt{5})/2]^n + c_2[(1 - \sqrt{5})/2]^n$ is known as the *Fibonacci sequence.*

Many of the orthogonal polynomials of differential equations and numerical analysis satisfy a second-order difference equation (recurrence relation) involving a discrete variable, say n, and a continuous variable, say z. One such is the *Chebshev equation* $y_{n+2} - 2zy_{n+1} + y_n = 0$ with the initial conditions $y_0 = 1$, $y_1 = z$ (*first-kind* Chebyshev polynomials) and $y_{n-1} = 0$, $y_0 = 1$ (second-kind Chebyshev polynomials). They are denoted $T_n(z)$ and $V_n(z)$, respectively. By iteration we find

$$T_0(z) = 1, \quad T_1(z) = z, \quad T_2(z) = 2z^2 - 1,$$

$$T_3(z) = 4z^3 - 3z, \quad T_4(z) = 8z^4 - 8z^2 + 1$$

$$V_0(z) = 0, \quad V_1(z) = 1, \quad V_2(z) = 2z,$$

$$V_3(z) = 4z^2 - 1, \quad V_4(z) = 8z^3 - 4z$$

and the general solution is $y_n(z) = c_1T_n(z) + c_2V_{n-1}(z)$,

Linear Equations with Constant Coefficients

The genral kth-order linear equation with constant coefficients is $\Sigma_{i=0}^{k} p_i y_{n+k-i} = g_n$, $p_0 = 1$. The solution to the corresponding homogeneous equation (obtained by setting $g_n = 0$) is as follows. (a) $y_n = \Sigma_{i=1}^{k} c_i\lambda_i^n$ if the λ_i are the distinct roots of the characteristic polynomial $p(\lambda) = \Sigma_{i=0}^{k} p_i\lambda^{k-i} = 0$. (b) if m_s is the multiplicity of the root λ_s, then the functions $y_{n,s} = u_s(n)\lambda_s^n$, where $u_s(n)$ are polynomials in n whose degree does not exceed $m_s - 1$, are solutions of the equation. Then the general solution of the homogeneous equation is $y_n = \Sigma_{i=1}^{d} a_i u_i(n)\lambda_i^n = \Sigma_{i=1}^{d} a_i \Sigma_{j=0}^{m_i-1} c_j n^j \lambda_i^n$. To this solution one adds any particular solution to obtain the general solution of the general equation.

Example 19.4.1. A model equation for the price p_n of a product, at the nth time, is $p_n + b/a(1 + \rho)p_{n-1} - (b/a)\rho p_{n-2} + (s_0 - d_0)/a = 0$. The equilibrium price is obtained by setting $p_n = p_{n-1} = p_{n-2} = p_e$, and one finds $p_e = (d_0 - s_0)/(a + b)$. The homogeneous equation has the characteristic polynomial $\lambda^2 + (b/a)(1 + \rho)\lambda - (b/a)\rho = 0$. With λ_1 and λ_2 as the roots the general solution of the full equation is $p_n = c_1\lambda_1^n + c_2\lambda_2^n + p_e$, since p_e is a solution of the full equation. This is one method for finding the solution of the nonhomogeneous equation.

Generating Function (z Transform)

An elegant way of solving linear difference equations with constant coefficients, among other applications, is by use of *generating functions* or, as an alternative, the z transform. The generating function of a sequence $\{y_n\}$, $n = 0, 1, 2, \ldots$, is the function $f(x)$ given by the formal series $f(x) = \Sigma_{n=0}^{\infty} y_n x^n$. The z transform of the same sequence is $z(x) = \Sigma_{n=0}^{\infty} y_n x^{-n}$. Clearly, $z(x) = f(1/x)$. A table of some important sequences is given in Table 19.4.1.

TABLE 19.4.1 Important Sequences

y_n	$f(x)$	Convergence Domain
1	$(1-x)^{-1}$	$\lvert x\rvert < 1$
n	$x(1-x)^{-2}$	$\lvert x\rvert < 1$
n^m	$xp_m(x)(1-x)^{-n-1*}$	$\lvert x\rvert < 1$
k^n	$(1-kx)^{-1}$	$\lvert x\rvert < k^{-1}$
e^{an}	$(1-e^a x)^{-1}$	$\lvert x\rvert < e^{-a}$
$k^n \cos an$	$\dfrac{1-kx\cos a}{1-2kx\cos a+k^2x^2}$	$\lvert x\rvert < k^{-1}$
$k^n \sin an$	$\dfrac{kx\sin a}{1-2kx\cos a+k^2x^2}$	$\lvert x\rvert < k^{-1}$
$\binom{n}{m}$	$x^m(1-x)^{-m-1}$	$\lvert x\rvert < 1$
$\binom{k}{n}$	$(1+x)^k$	$\lvert x\rvert < 1$

* The term $p_m(z)$ is a polynomial of degree m satisfying $p_{m+1}(z) = (mz+1)\cdot p_m(z) + z(1-z)\,p'_m(x)$, $p_1 = 1$.

To solve the linear difference equation $\Sigma_{i=0}^{k} p_i y_{n+k-i} = 0$, $p_0 = 1$ we associate with it the two formal series $P = p_0 + p_1x + \cdots + p_kx^k$ and $Y = y_0 + y_1x + y_2x^{2} + \cdots$. If $p(x)$ is the characteristic polynomial then $P(x) = x^kp(1/x) = \bar{p}(x)$. The *product* of the two series is $Q = YP = q_0 + q_1x + \cdots + q_{k-1}x^{k-1} + q_kx^k + \cdots$ where $q_n = \Sigma_{i=0}^{n} p_i y_{n-i}$. Because $p_{k+1} = p_{k+2} = \cdots = 0$, it is obvious that $q_{k+1} = q_{k+2} = \cdots = 0$ — that is, Q is a polynomial (formal series with finite number of terms). Then $Y = P^{-1}Q = q(x)/\bar{p}(x) = q(x)/x^kp(1/x)$, where p is the characteristic polynomial and $q(x) = \Sigma_{i=0}^{k} q_ix^i$. The roots of $\bar{p}(x)$ are x_i^{-1} where the x_i are the roots of $p(x)$.

Theorem 1. If the roots of $p(x)$ are less than one in absolute value, then $Y(x)$ converges for $\lvert x\rvert < 1$.

Theorem 2. If $p(x)$ has no roots greater than one in absolute value and those on the unit circle are simple roots, then the coefficients y_n of Y are bounded. Now $q_k = g_0$, $q_{n+k} = g_n$, and $Q(x) = Q_1(x) + x^kQ_2(x)$. Hence $\Sigma_{i=1}^{\infty} y_ix^i = [Q_1(x) + x^kQ_2(x)]/[\bar{p}(x)]$.

Example 19.4.2. Consider the equation $y_{n+1} + y_n = -(n+1)$, $y_0 = 1$. Here $Q_1 = 1$, $Q_2 = -\Sigma_{n=0}^{\infty}(n+1)x^n = -1/(1-x)^2$.

$$G(x) = \frac{1 - x/(1-x)^2}{1+x} = \frac{5}{4}\frac{1}{1+x} - \frac{1}{4}\frac{1}{1-x} - \frac{1}{2}\frac{x}{(1-x)^2}$$

Using the table term by term, we find $\Sigma_{n=0}^{\infty} y_nx^n = \Sigma_{n=0}^{\infty}[{}^5/_4(-1)^n - {}^1/_4 - {}^1/_2\, n]x^n$, so $y_n = {}^5/_4(-1)^n - {}^1/_4 - {}^1/_2\, n$.

19.5 Differential Equations

William F. Ames

Any equation involving derivatives is called a *differential equation*. If there is only one independent variable the equation is termed a *total differential equation* or an *ordinary differential equation*. If there is more than one independent variable the equation is called a *partial differential equation*. If the highest-order derivative is the nth then the equation is said to be nth order. If there is no function of the dependent variable and its derivatives other than the linear one, the equation is said to be *linear*. Otherwise, it is *nonlinear*. Thus $(d^3y/dx^3) + a(dy/dx) + by = 0$ is a *linear* third-order ordinary (total) differential equation. If we replace by with by^3, the equation becomes nonlinear. An example of a second-order linear partial differential equation is the famous wave equation $(\partial^2u/\partial x^2) - a^2(\partial^2u/\partial t^2) = f(x)$. There are two independent variables x and t and $a^2 > 0$ (of course). If we replace $f(x)$ by $f(u)$ (say u^3 or $\sin u$) the equation is nonlinear. Another example of a nonlinear third-order partial differential equation is $u_t + uu_x = au_{xxx}$. This chapter uses the common subscript notation to indicate the partial derivatives.

Now we briefly indicate some methods of solution and the solution of some commonly occurring equations.

Ordinary Differential Equations

First-Order Equations

The *general* first-order equation is $f(x, y, y') = 0$. Equation capable of being written in either of the forms $y' = f(x)g(y)$ or $f(x)g(y)y' + F(x)G(y) = 0$ are *separable* equations. Their solution is obtained by using $y' = dy/dx$ and writing the equations in differential form as $dy/g(y) = f(x)dx$ or $g(y)[dy/G(y)] = -F(x)[dx/f(x)]$ and integrating. An example is the famous *logistic* equation of inhibited growth $(dy/dt) = ay(1 - y)$. The integral of $dy/y(1 - y) = adt$ is $y = 1/[1 + (y_0^{-1} - 1)e^{-at}]$ for $t \geq 0$ and $y(0) = y_0$ (the initial state called the *initial condition*).

Equations may not have unique solutions. An example is $y' = 2y^{1/2}$ with the initial condition $y(0) = 0$. One solution by separation is $y = x^2$. But there are an *infinity* of others — namely, $y_a(x) = 0$ for $-\infty < x \leq a$, and $(x - a)^2$ for $a \leq x < \infty$.

If the equation $P(x, y)dy + Q(x, y)dy = 0$ is reducible to

$$\frac{dy}{dx} = f\left(\frac{y}{x}\right) \quad \text{or} \quad \frac{dy}{dx} = f\left(\frac{a_1x + b_1y + c_1}{a_2x + b_2y + c_2}\right)$$

the equation is called *homogenous* (nearly homogeneous). The first form reduces to the separable equation $u + x(du/dx) = f(u)$ with the substitution $y/x = u$. The nearly homogeneous equation is handled by setting $x = X + a$, $y = Y + \beta$, and choosing α and β so that $a_1\alpha + b_1\beta + c_1 = 0$ and $a_2\alpha + b_2\beta + c_2 = 0$. If $\begin{vmatrix} a_1 & b_1 \\ a_2 & b_2 \end{vmatrix} \neq 0$ this is always possible; the equation becomes $dY/dX = [a_1 + b_1(Y/X)]/[a_2 + b_2(Y/X)]$ and the substitution $Y = Xu$ gives a separable equation. If $\begin{vmatrix} a_1 & b_1 \\ a_2 & b_2 \end{vmatrix} = 0$ then $a_2x + b_2y = k(a_1x + b_1y)$ and the equation becomes $du/dx = a_1 + b_1(u + c_1)/(ku + c_2)$, with $u = a_1x + b_1y$. Lastly, any equation of the form $dy/dx = f(ax + by + c)$ transforms into the separable equation $du/dx = a + bf(u)$ using the change of variable $u = ax + by + c$.

The general first-order linear equation is expressible in the form $y' + f(x)y = g(x)$. It has the *general solution* (a solution with an arbitrary constant c)

$$y(x) = \exp\left[-\int f(x)\,dx\right]\left\{c + \int \exp[f(x)]g(x)\,dx\right\}$$

Two noteworthy examples of first-order equations are as follows:

1. An often-occurring nonlinear equation is the *Bernoulli equation,* $y' + p(x)y = g(x)y^{\alpha}$, with α real, $\alpha \neq 0$, $\alpha \neq 1$. The transformation $z = y^{1-\alpha}$ converts the equation to the linear first-order equation $z' + (1 - \alpha)p(x)z = (1 - \alpha)q(x)$.
2. The famous *Riccati equation,* $y' = p(x)y^2 + q(x)y + r(x)$, cannot in general be solved by integration. But some useful transformations are helpful. The substitution $y = y_1 + u$ leads to the equation $u' - (2py_1 + q)u = pu^2$, which is a Bernoulli equation for u. The substitution $y = y_1 + v^{-1}$ leads to the equation $v' + (2py_1 + q)v + p = 0$, which is a linear first-order equation for v. Once either of these equations has been solved, the general solution of the Riccati equation is $y = y_1 + u$ or $y = y_1 + v^{-1}$.

Second-Order Equations

The simplest of the second-order equations is $y'' + ay' + by = 0$ (a, b real), with the initial conditions $y(x_0) = y_0$, $y'(x_0) = y_0'$ or the boundary conditions $y(x_0) = y_0$, $y(x_1) = y_1$. The general solution of the equation is given as follows.

1. $a^2 - 4b > 0$, $\lambda_1 = {}^1/_2\,(-a + \sqrt{a^2 - 4b})$, $\lambda_2 = {}^1/_2\,(-a - \sqrt{a^2 - 4b})$
   $y = c_1 \exp(\lambda_1 x) + c_2 \exp(\lambda_2 x)$
2. $a^2 - 4b = 0$, $\lambda_1 = \lambda_2 = -\frac{a}{2}$, $y = (c_1 + c_2 x)\exp(\lambda_1 x)$
3. $a^2 - 4b < 0$, $\lambda_1 = {}^1/_2\,(-a + i\sqrt{4b - a^2})$, $\lambda_2 = {}^1/_2\,(-a - i\sqrt{4b - a^2})$,
   $i^2 = -1$

   With $p = -a/2$ and $q = {}^1/_2\sqrt{4b - a^2}$,

   $$y = c_1 \exp[(p + iq)x] + c_2 \exp[(p - iq)x] = \exp(px)[A\sin qx + B\cos qx]$$

   The initial conditions or boundary conditions are used to evaluate the arbitrary constants c_1 and c_2 (or A and B).

   Note that a linear problem with specified data may not have a solution. This is especially serious if numerical methods are employed without serious thought.

For example, consider $y'' + y = 0$ with the boundary condition $y(0) = 1$ and $y(\pi) = 1$. The general solution is $y = c_1 \sin x + c_2 \cos x$. The first condition $y(0) = 1$ gives $c_2 = 1$, and the second condition requires $y(\pi) = c_1 \sin \pi + \cos \pi$ or "$1 = -1$," which is a *contradiction.*

Example 19.5.1 — The Euler Strut. When a strut of uniform construction is subject to a compressive load P it exhibits no transverse displacement until P exceeds some critical value P_1. When this load is exceeded, buckling occurs and large deflections are produced as a result of small load changes. Let the rod of length ℓ be placed as shown in Figure 19.5.1.

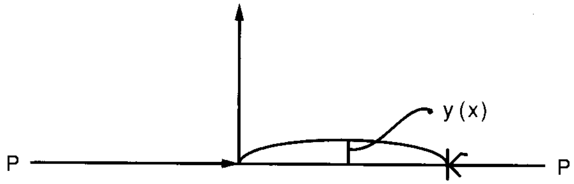

FIGURE 19.5.1

From the linear theory of elasticity (Timoshenko), the transverse displacement $y(x)$ satisfies the linear second-order equation $y'' + (Py/EI) = 0$, where E is the modulus of elasticity and I is the moment of inertia of the strut. The boundary conditions are $y(0) = 0$ and $y(a) = 0$. With $k^2 = P/EI$ the general solution is $y = c_1 \sin kx + c_2 \cos kx$. The condition $y(0) = 0$ gives $c_2 = 0$. The second condition gives $c_1 \sin ka = 0$. Since $c_1 = 0$ gives the trival solution $y = 0$ we must have $\sin ka = 0$. This occurs for $ka = n\pi$, $n = 0, 1, 2, \ldots$ (these are called *eigenvalues*). The first nontrivial solution occurs for $n = 1$ — that is, $k = \pi/a$ — whereupon $y_1 = c_1 \sin(\pi/a)$, with arbitrary c_1. Since $P = EIk^2$ the critical compressive load is $P_1 = EI\,\pi^2/a^2$. This is the buckling load. The weakness of the linear theory is its failure to model the situation when buckling occurs.

Example 19.5.2 — Some Solvable Nonlinear Equations. Many physical phenomena are modeled using nonlinear second-order equations. Some general cases are given here.

1. $y'' = f(y)$, *first integral* $(y')^2 = 2\int f(y)\,dy + c$.
2. $f(x, y', y'') = 0$. Set $p = y'$ and obtain a first-order equation $f(x, p, dp/dx) = 0$. Use first-order methods.
3. $f(y, y', y'') = 0$. Set $p = y'$ and then $y'' = p(dp/dy)$ so that a first-order equation $f\,[y, p, p(dp/dy) = 0$ for p as a function of y is obtained.
4. The *Riccati transformation* $du/dx = yu$ leads to the Riccati chain of equations, which linearize by raising the order. Thus,

Equation in y	Equation in u
1. $y' + y^2 = f(x)$	$u'' = f(x)u$
2. $y'' + 3yy' + y^3 = f(x)$	$u''' = f(x)u$
3. $y''' + 6y^2y' + 3(y')^2 + 4yy'' = f(x)$	$u^{(iv)} = f(x)u$

This method can be generalized to $u' = a(x)yu$ or $u' = a(x)f(u)y$.

Second-Order Inhomogeneous Equations

The general solution of $a_0(x)y'' + a_1(x)y' + a_2(x)y = f(x)$ is $y = y_H(x) + y_p(x)$ where $y_H(x)$ is the general solution of the homogeneous equation (with the right-hand side zero) and y_p is the particular integral of the equation. Construction of particular integrals can sometimes be done by the *method of undetermined coefficients*. See Table 19.5.1. This applies only to the linear constant coefficient case in which the function $f(x)$ is a linear combination of a polynomial, exponentials, sines and cosines, and some products of these functions. This method has as its base the observation that repeated differentiation of such functions gives rise to similar functions.

TABLE 19.5.1 Method of Undetermined Coefficients — Equation $L(y) = f(x)$ (Constant Coefficients)

Terms in $f(x)$	Terms To Be Included in $y_p(x)$
1. Polynomial of degree n	(i) If $L(y)$ contains y, try $y_p = a_0x^n + a_1x^{n-1} + \cdots + a_n$, (ii) If $L(y)$ does not contain y and lowest-order derivative is $y^{(r)}$, try $y_p = a_0x^{n+r} + \cdots + a_nx^r$.
2. $\sin qx$, $\cos qx$	(i) $\sin qx$ and/or $\cos qx$ are not in y_H; $y_p = B \sin qx + C \cos qx$. (ii) y_H contains terms of form $x^r \sin qx$ and/or $x^r \cos qx$ for $r = 0, 1, \ldots, m$; include in y_p terms of the form $a_0x^{m+1} \sin qx + a_1x^{m+1} \cos qx$.
3. e^{ax}	(i) y_H does not contain e^{ax}; include Ae^{ax} in y_p. (ii) y_H contains $e^{ax}, xe^{ax}, \ldots, x^ne^{ax}$; include in y_p terms of the form $Ax^{n+1}e^{ax}$,
4. $e^{px} \sin qx$, $e^{px} \cos qx$	(i) y_H does not contain these terms; in y_p include $Ae^{px} \sin qx + Be^{px} \cos qx$. (ii) y_H contains $x^r e^{px} \sin qx$ and/or $x^r e^{px} \cos qx$; $r = 0,1, \ldots, m$ include in y_p. $Ax^{m+1}e^{px} \sin qx + Bx^{m+1} e^{px} \cos qx$.

Example 19.5.3. Consider the equation $y'' + 3y' + 2y = \sin 2x$. The characteristic equation of the homogeneous equation $\lambda^2 + 3\lambda + 2 = 0$ has the two roots $\lambda_1 = -1$ and $\lambda_2 = -2$. Consequently, $y_H = c_1e^{-x} + c_2e^{-2x}$. Since $\sin 2x$ is not linearly dependent on the exponentials and since $\sin 2x$ repeats after two differentiations, we assume a particular solution with undetermined coefficients of the form $y_p(x) = B \sin 2x + C \cos 2x$. Substituting into the original equation gives $-(2B + 6C) \sin 2x + (6B - 2C) \cos 2x = \sin 2x$. Consequently, $-(2B + 6C) = 1$ and $6B - 2C = 0$ to satisfy the equation. These two equations in two unknowns have the solution $B = -1/20$ and $C = -3/20$. Hence $y_p = -1/20 (\sin 2x + 3 \cos 2x)$ and $y = c_1e^{-x} + c_2e^{-2x} - 1/20 (\sin 2x + 3 \cos 2x)$.

A general method for finding $y_p(x)$ called *variation of parameters* uses as its starting point $y_H(x)$. This method applies to *all* linear differential equations irrespective of whether they have constant coefficients. But it assumes $y_H(x)$ is known. We illustrate the idea for $a(x)y'' + b(x)y' + c(x)y = f(x)$. If the solution of the homogeneous equation is $y_H(x) = c_1\phi_1(x) + c_2\phi_2(x)$, then vary the parameters c_1 and c_2 to seek $y_p(x)$ as $y_p(x) = u_1(x)\phi_1(x) + u_2(x)\phi_2(x)$. Then $y_P' = u_1 \phi_1' + u_2 \phi_2' + u_1' \phi_1 + u_2' \phi_2$ and choose $u_1' \phi_1 + u_2' \phi_2 = 0$. Calculating y_P'' and setting in the original equation gives $a(x)\, u_1'\phi_1' + a(x)\, u_2'\phi_2' = f$. Solving the last two equations for u_1' and u_2' gives $u_1' = -\phi_2 f/wa$, $u_2' = \phi_1 f/wa$, where $w = \phi_1 \phi_2' - \phi_1' \phi_2 \neq 0$. Integrating the general solution gives $y = c_1\phi_1(x) + c_2\phi_2(x) - \{\int[\phi_2 f(x)]/wa\}\phi_1(x) + [\int(\phi_1 f/wa)dx]\phi_2(x)$.

Example 19.5.4. Consider the equations $y'' - 4y = \sin x/(1 + x^2)$ and $y_H = c_1e^{-2x} + c_2e^{-2x}$. With $\phi_1 = e^{2x}$, and $\phi_2 = e^{-2x}$, $w = 4$, so the general solution is

$$y = c_1e^{2x} + c_2e^{-2x} - \frac{e^{-2x}}{4}\int \frac{e^{2x}\sin x}{1+x^2}\,dx + \frac{e^{2x}}{4}\int \frac{e^{-2x}\sin x}{1+x^2}\,dx$$

The method of variation of parameters can be generalized as described in the references.

Higher-order systems of linear equations with constant coefficients are treated in a similar manner. Details can be found in the references.

Series Solution

The solution of differential equations can only be obtained in closed form in special cases. For all others, series or approximate or numerical solutions are necessary. In the simplest case, for an initial value problem, the solution can be developed as a Taylor series expansion about the point where the initial data are specified. The method fails in the *singular case* — that is, a point where the coefficient of the highest-order derivative is zero. The general method of approach is called the *Frobenius method.*

To understand the nonsingular case consider the equation $y'' + xy = x^2$ with $y(2) = 1$ and $y'(2) = 2$ (an initial value problem). We seek a series solution of the form $y(x) = a_0 + a_1(x - 2) + a_2(x - 2)^2 + \cdots$. To proceed, set $1 = y(2) = a_0$, which evaluates a_0. Next $y'(x) = a_1 + 2a_2(x - 2) + \cdots$, so $2 = y'(2) = a_1$ or $a_1 = 2$. Next $y''(x) = 2a_2 + 6a_3(x - 2) + \cdots$. and from the equation, $y'' = x^2 - xy$, so $y''(2) = 4 - 2y(2) = 4 - 2 = 2$. Hence $2 = 2a_2$ or $a_2 = 1$. Thus, to third-order $y(x) = 1 + 2(x - 2) + (x - 2)^2 + R_2(x)$, where the remainder $R_2(x)$ $[(x-2)^3/3]y'''(\xi)$, where $2 < \xi < x$ can be bounded for each x by finding the maximum of $y'''(x) = 2x - y - xy'$. The third term of the series follows by evaluating $y'''(2) = 4 - 1 - 2 \cdot 2 = -1$, so $6a_3 = -1$ or $a_3 = -1/6$.

By now the nonsingular process should be familiar. The algorithm for constructing a series solution about a nonsingular (ordinary) point x_0 of the equation $P(x)y'' + Q(x)y' + R(x)y = f(x)$ (note that $P(x_0) \neq 0$) is as follows:

1. Substitute into the differential equation the expressions

$$y(x) = \sum_{n=0}^{\infty} a_n\left(x - x_0\right)^n, \qquad y'(x) = \sum_{n=1}^{\infty} na_n\left(x - x_0\right)^{n-1}, \qquad y''(x) = \sum_{n=2}^{\infty} n(n-1)a_n\left(x - x_0\right)^{n-2}$$

2. Expand $P(x)$, $Q(x)$, $R(x)$, and $f(x)$ about the point x_0 in a power series in $(x - x_0)$ and substitute these series into the equation.
3. Gather all terms involving the same power of $(x - x_0)$ to arrive at an identity of the form $\Sigma_{n=0}^{\infty} A_n(x - x_0)^n \equiv 0$.
4. Equate to zero each coefficient A_n of step 3.
5. Use the expressions of step 4 to determine a_2, a_3, … in terms of a_0, a_1 (we need two arbitrary constants) to arrive at the general solution.
6. With the given initial conditions, determine a_0 and a_1.

If the equation has a regular singular point — that is, a point x_0 at which $P(x)$ vanishes and a series expansion is sought about that point — a solution is sought of the form $y(x) = (x - x_0)^r \Sigma_{n=0}^{\infty} a_n(x - x_0)^n$, $a_0 \neq 0$ and the index r and coefficients a_n must be determined from the equation by an algorithm analogous to that already described. The description of this Frobenius method is left for the references.

Partial Differential Equations

The study of partial differential equations is of continuing interest in applications. It is a vast subject, so the focus in this chapter will be on the most commonly occurring equations in the engineering literature — the second-order equations in two variables. Most of these are of the three basic types: elliptic, hyperbolic, and parabolic.

Elliptic equations are often called *potential equations* since they occur in potential problems where the potential may be temperature, voltage, and so forth. They also give rise to the steady solutions of parabolic equations. They require boundary conditions for the complete determination of their solution.

Hyperbolic equations are often called *wave equations* since they arise in the propagation of waves. For the development of their solutions, initial and boundary conditions are required. In principle they are solvable by the method of characteristics.

Parabolic equations are usually called *diffusion equations* because they occur in the transfer (diffusion) of heat and chemicals. These equations require initial conditions (for example, the initial temperature) and boundary conditions for the determination of their solutions.

Partial differential equations (PDEs) of the second order in two independent variables (x, y) are of the form $a(x, y)u_{xx} + b(x, y)u_{xy} + c(x, y)u_{yy} = E(x, y, u, u_x, u_y)$. If $E = E(x, y)$ the equation is linear; if E depends also on u, u_x, and u_y, it is said to be *quasilinear,* and if E depends only on x, y, and u, it is *semilinear.* Such equations are classified as follows: If $b^2 - 4ac$ is less than, equal to, or greater than zero at some point (x, y), then the equation is elliptic, parabolic, or hyperbolic, respectively, at that point. A PDE of this form can be transformed into canonical (standard) forms by use of new variables. These standard forms are most useful in analysis and numerical computations.

For hyperbolic equations the standard form is $u_{\xi\eta} = \phi(u, u_\eta, u_\xi, \eta, \xi)$, where $\xi_x/\xi_y = (-b + \sqrt{b^2 - 4ac})/2a$, and $\eta_x/\eta_y = (-b - \sqrt{b^2 - 4ac})/2a$. The right-hand sides of these equations determine the so-called characteristics $(dy/dx)|_+ = (-b + \sqrt{b^2 - 4ac})/2a$, $(dy/dx)|_- = (-b - \sqrt{b^2 - 4ac})/2a$.

Example 19.5.5. Consider the equation $y^2u_{xx} - x^2u_{yy} = 0$, $\xi_x/\xi_y = -x/y$, $\eta_x/\eta_y = x/y$, so $\xi = y^2 - x^2$ and $\eta = y^2 + x^2$. In these new variables the equation becomes $u_{\xi\eta} = (\xi u_\eta - \eta u_\xi)/2(\xi^2 - \eta^2)$.

For parabolic equations the standard form is $u_{\xi\xi} = \phi(u, u_\eta, u_\xi, \eta, \xi)$ or $u_{\eta\eta} = \phi(u, u_\eta, u_\xi, \xi, \eta)$, depending upon how the variables are defined. In this case $\xi_x/\xi_y = -b/2a$ if $a \neq 0$, and $\xi_x/\xi_y = -b/2c$ if $c \neq 0$. Only ξ must be determined (there is only one characteristic) and η can be chosen as any function that is linearly independent of ξ.

Example 19.5.6. Consider the equation $y^2u_{xx} - 2xyu_{xy} + x^2u_{yy} + u_y = 0$. Clearly, $b^2 - 4ac = 0$. Neither a nor c is zero so either path can be chosen. With $\xi_x/\xi_y = -b/2a = x/y$, there results $\xi = x^2 + y^2$. With $\eta = x$, the equation becomes $u_{\eta\eta} = [2(\xi + \eta)u_\xi + u_\eta]/(\xi - \eta^2)$.

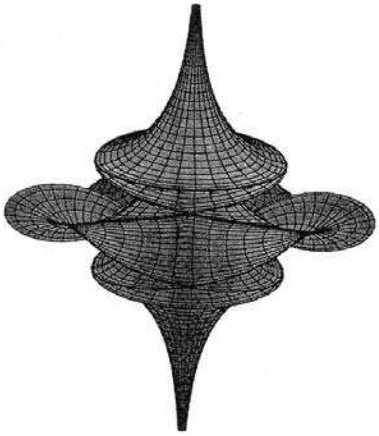

Figure 19.5.2

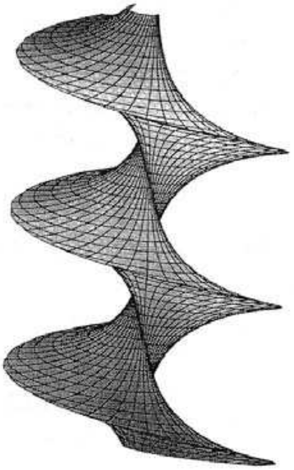

Figure 19.5.3

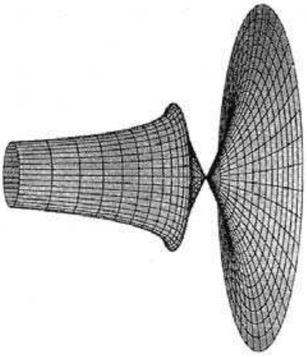

Figure 19.5.4

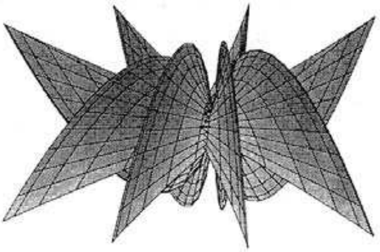

Figure 19.5.5

FIGURE 19.5.2 to 19.5.5 The mathematical equations used to generate these three-dimensional figures are worth a thousand words. The figures shown illustrate some of the nonlinear ideas of engineering, applied physics, and chemistry. Figure 19.5.2 represents a breather soliton surface for the sine-Gordon equation $w_{uv} = \sin w$ generated by a Backlund transformation. A single-soliton surface for the sine-Gordon equation $w_{uv} = \sin w$ is illustrated in Figure 19.5.3. Figure 19.5.4 represents a single-soliton surface for the Tzitzecia-Dodd-Bullough equation associated with an integrable anisentropic gas dynamics system. Figure 19.5.5 represents a single-soliton Bianchi surface.
The solutions to the equations were developed by W. K. Schief and C. Rogers at the Center for Dynamical Systems and Nonlinear Studies at the Georgia Institute of Technology and the University of New South Wales in Sydney, Australia. All of these three-dimensional projections were generated using the MAPLE software package. (Figures courtesy of Schief and Rogers).

For *elliptic equations* the standard form is $u_{\alpha\alpha} + u_{\beta\beta} = \phi(u, u_\alpha, u_\beta, \alpha, \beta)$, where ξ and η are determined by solving the ξ and η equations of the hyperbolic system (they are complex) and taking $\alpha = (\eta + \xi)/2$, $\beta = (\eta - \xi)/2i(i^2 = -1)$. Since ξ and η are complex conjugates, both α and β are real.

Example 19.5.7. Consider the equation $y^2u_{xx} + x^2u_{yy} = 0$. Clearly, $b^2 - 4ac < 0$, so the equation is elliptic. Then $\xi_x/\xi_y = -ix/y$, $\eta_x/\eta_y = ix/y$, so $\alpha = (\eta + \xi)/2 = y^2$ and $\beta = (\eta - \xi)/2i = x^2$. The standard form is $u_{\alpha\alpha} + u_{\beta\beta} = -(u_\alpha/2\alpha + u_\beta/2\beta)$.

Methods of Solution

Separation of Variables. Perhaps the most elementary method for solving linear PDEs with homogeneous boundary conditions is the method of *separation of variables.* To illustrate, consider $u_t - u_{xx} = 0$,

$u(x, 0) = f(x)$ (the initial condition) and $u(0, t) = u(1, t) = 0$ for $t > 0$ (the boundary conditions). A solution is assumed in "separated form" $u(x, t) = X(x)T(t)$. Upon substituting into the equation we find $\dot{T}/T = X''/X$ (where $\dot{T} = dT/dt$ and $X'' = d^2X/dx^2$). Since $T = T(t)$ and $X = X(x)$, the ratio must be constant, and for finiteness in t the constant must be negative, say $-\lambda^2$. The solutions of the separated equations $X'' + \lambda^2 X = 0$ with the boundary conditions $X(0) = 0$, $X(1) = 0$, and $\dot{T} = -\lambda^2 T$ are $X = A \sin \lambda x + B \cos \lambda x$ and $T = Ce^{-\lambda^2 t}$, where A, B, and C are arbitrary constants. To satisfy the boundary condition $X(0) = 0$, $B = 0$. An infinite number of values of λ (eigenvalues), say $\lambda_n = n\pi (n = 1, 2, 3, \ldots)$, permit all the eigenfunctions $X_n = b_n \sin \lambda_n x$ to satisfy the other boundary condition $X(1) = 0$. The solution of the equation and boundary conditions (not the initial condition) is, by superposition, $u(x, t) = \Sigma_{n=1}^{\infty} b_n e^{-n^2\pi^2 t} \cdot \sin n\pi x$ (a Fourier sine series), where the b_n are arbitrary. These values are obtained from the initial condition using the orthogonality properties of the trigonometric function (e.g., $\int_{-\pi}^{\pi} \sin mx \sin n\, x\, d\, x$ is 0 for $m \neq n$ and is π for $m = n \neq 0$) to be $b_n = 2 \int_0^1 f(r) \sin n\, \pi\, r\, d\, r$. Then the solution of the problem is $u(x, t) = \Sigma_{n=1}^{\infty} [2 \int_0^1 f(r) \sin n\, \pi\, r\, d\, r]\, e^{-n^2\pi^2 t} \sin n\, \pi\, x$, which is a Fourier sine series.

If $f(x)$ is a piecewise smooth or a piecewise continuous function defined for $a \le x \le b$, then its Fourier series within $a \le x \le b$ as its fundamental interval (it is extended periodically ouside that interval) is

$$f(x) \sim \tfrac{1}{2} a_0 + \sum_{n=1}^{\infty} a_n \cos\left[2n\pi x/(b-a)\right] + b_n \sin\left[2n\pi x/(b-a)\right]$$

where

$$a_n = \left[\frac{2}{(b-a)}\right] \int_a^b f(x) \cos\left[2n\pi x/(b-a)\right] dx, \quad n = 0,\ 1,\ \ldots$$

$$b_n = \left[\frac{2}{(b-a)}\right] \int_a^b f(x) \sin\left[2n\pi x/(b-a)\right] dx, \quad n = 1,\ 2,\ \ldots$$

The Fourier sine series has $a_n \equiv 0$, and the Fourier cosine series has $b_n \equiv 0$. The symbol ~ means that the series converges to $f(x)$ at points of continuity, and at the (allowable) points of finite discontinuity the series converges to the *average value* of the discontinuous values.

Caution: This method *only* applies to linear equations with homogeneous boundary conditions. Linear equations with variable coefficients use other orthogonal functions, such as the Besel functions, Laguerre functions, Chebyshev functions, and so forth.

Some inhomogeneous boundary value problems can be transformed into homogeneous ones. Consider the problem $u_t - u_{xx} = 0$, $0 \le x \le 1$, $0 \le t < \infty$ with initial condition $u(x, 0) = f(x)$, and boundary conditions $u(0, t) = g(t)$, $u(1, t) = h(t)$. To homogenize the boundary conditions set $u(x, t) = w(x, t) + x[h(t) - g(t)] + g(t)$ and then solve $w_t - w_x = [\dot{g}(t) - \dot{h}(t)]x - \dot{g}(t)$ with the initial condition $w(x, 0) = f(x) - x[h(0) - g(0)] + g(0)$ and $w(0, t) = w(1, t) = 0$.

Operational Methods. A number of integral transforms are useful for solving a variety of linear problems. To apply the Laplace transform to the problem $u_t - u_{xx} = \delta(x)\, \delta(t)$, $-\infty < x < \infty$, $0 \le t$ with the initial condition $u(x, 0^-) = 0$, where δ is the Dirac delta function, we multiply by e^{-st} and integrate with respect to t from 0 to ∞. With the Laplace transform of $u(x, t)$ denoted by $U(x, s)$ — that is, $U(x, s) = \int_0^{\infty} e^{-st} u(x, t)\, dt$ — we have $sU - U_{xx} = \delta(x)$, which has the solution

$$U(x,s) = A(s)e^{-x\sqrt{s}} + B(s)e^{x\sqrt{s}} \qquad \text{for } x > 0$$

$$U(x,s) = C(s)e^{-x\sqrt{s}} + D(s)e^{x\sqrt{s}} \qquad \text{for } x < 0$$

Clearly, $B(s) = C(s) = 0$ for bounded solutions as $|x| \to \infty$. Then, from the boundary condition, $U(0^+, s) - U(0^-, s) = 0$ and integration of $sU - U_{xx} = \delta(x)$ from 0^- to 0^+ gives $U_x(0^+, s) - U(0^-, s) = -1$, so $A = D =$

$1/2\sqrt{s}$. Hence, $U(x, s) = (1/2\sqrt{s})e^{-\sqrt{s}|x|}$ and the inverse is $u(x, t) = (1/2\,\pi i)\int_\Gamma e^{st}U(x, s)\,ds$, where Γ is a Bromwich path, a vertical line taken to the right of all singularities of U on the sphere.

Similarity (Invariance). This very useful approach is related to dimensional analysis; both have their foundations in group theory. The three important transformations that play a basic role in Newtonian mechanics are translation, scaling, and rotations. Using two independent variables x and t and one dependent variable $u = u(x, t)$, the *translation group* is $\bar{x} = x + \alpha a$, $\bar{t} = t + \beta a$, $\bar{u} = u + \gamma a$; the *scaling group* is $\bar{x} = a^\alpha x$, $\bar{t} = a^\beta t$, and $\bar{u} = a^\gamma u$; the *rotation group* is $\bar{x} = x\cos a + t\sin a$, $\bar{t} = t\cos a - x\sin a$, $\bar{u} = u$, with a nonnegative real number a. Important in which follows are the *invariants* of these groups. For the translation group there are two $\eta = x - \lambda t$, $\lambda = \alpha/\beta$, $f(\eta) = u - \varepsilon t$, $\varepsilon = \gamma/\beta$ or $f(\eta) = u - \theta x$, $\theta = \gamma/\alpha$; for the scaling group the invariants are $\eta = x/t^{\alpha/\beta}$ (or $t/x^{\beta/\alpha}$) and $f(\eta) = u/t^{\gamma/\beta}$ (or $u/x^{\gamma/\alpha}$); for the rotation group the invariants are $\eta = x^2 + t^2$ and $u = f(\eta) = f(x^2 + t^2)$.

If a PDE and its data (initial and boundary conditions) are left invariant by a transformation group, then similar (invariant) solutions are sought using the invariants. For example, if an equation is left invariant under scaling, then solutions are sought of the form $u(x, t) = t^{\gamma/\beta} f(\eta)$, $\eta = xt^{-\alpha/\beta}$ or $u(x, t) = x^{\gamma/\alpha} f(tx^{-\beta/\alpha})$; invariance under translation gives solutions of the form $u(x, t) = f(x - \lambda t)$; and invariance under rotation gives rise to solutions of the form $u(x, t) = f(x^2 + t^2)$.

Examples of invariance include the following:

1. The equation $u_{xx} + u_{yy} = 0$ is invariant under rotation, so we search for solutions of the form $u = f(x^2 + y^2)$. Substitution gives the ODE $f' + \eta f'' = 0$ or $(\eta f')' = 0$. The solution is $u(x, t) = c\ln\eta = c\ln(x^2 + t^2)$, which is the (so-called) fundamental solution of Laplace's equation.
2. The nonlinear diffusion equation $u_t = (u^n u_x)_x$ $(n > 0)$, $0 \le x$, $0 \le t$, $u(0, t) = ct^n$ is invariant under scaling with the similar form $u(x, t) = t^n f(\eta)$, $\eta = xt^{-(n+1)/2}$. Substituting into the PDE gives the equation $(f^n f')' + ((n + 1)/2)\eta f' - nf = 0$, with $f(0) = c$ and $f(\infty) = 0$. Note that the equation is an ODE.
3. The wave equation $u_{xx} - u_{tt} = 0$ is invariant under translation. Hence, solutions exist of the form $u = f(x - \lambda t)$. Substitution gives $f''(1 - \lambda^2) = 0$. Hence, $\lambda = \pm 1$ or f is linear. Rejecting the trivial linear solution we see that $u = f(x - t) + g(x + t)$, which is the general (d'Alembert) solution of the wave equation; the quantities $x - t = \alpha$, $x + t = \beta$ are the characteristics of the next section.

The construction of all transformations that leave a PDE invariant is a solved problem left for the references.

The study of "solitons" (solitary traveling waves with special properties) has benefited from symmetry considerations. For example, the nonlinear third-order (Korteweg-de Vries) equation $u_t + uu_x - au_{xxx} = 0$ is invariant under translation. Solutions are sought of the form $u = f(x - \lambda t)$, and f satisfies the ODE, in $\eta = x - \lambda t$, $-\lambda f' + ff' - af''' = 0$.

Characteristics. Using the characteristics the solution of the hyperbolic problem $u_{tt} - u_{xx} = p(x, t)$, $-\infty < x < \infty$, $0 \le t$, $u(x, 0) = f(x)$, $u_t(x, 0) = h(x)$ is

$$u(x,t) = \tfrac{1}{2}\int_0^t d\tau \int_{x-(t-\tau)}^{x+(t-\tau)} p(\xi,\tau)\,d\xi + \tfrac{1}{2}\int_{x-t}^{x+t} h(\xi)\,d\xi + \tfrac{1}{2}\left[f(x+t) + f(x-t)\right]$$

The solution of $u_{tt} - u_{xx} = 0$, $0 \le x < \infty$, $0 \le t < \infty$, $u(x, 0) = 0$, $u_t(x, 0) = h(x)$, $u(0, t) = 0$, $t > 0$ is $u(x, t) = {}^1/_2 \int_{-x+t}^{x+t} h(\xi)\,d\xi$.

The solution of $u_{tt} - u_{xx} = 0$, $0 \le x < \infty$, $0 \le t < \infty$, $u(x, 0) = 0$, $u_t(x, 0) = 0$, $u(0, t) = g(t)$, $t > 0$ is

$$u(x,t) = \begin{cases} 0 & \text{if } t < x \\ g(t-x) & \text{if } t > x \end{cases}$$

From time to time, lower-order derivatives appear in the PDE in use. To remove these from the equation $u_{tt} - u_{xx} + au_x + bu_t + cu = 0$, where a, b, and c are constants, set $\xi = x + t$, $\mu = t - x$, whereupon $u(x, t) = u[(\xi - \mu)/2, (\xi + \mu)/2] = U(\xi, \mu)$, where $U_{\xi\mu} + [(b + a)/4]\, U_\xi + [(b - a)/4]\, U_\mu + (c/4)U = 0$. The transformation $U(\xi, \mu) = W(\xi, \mu) \exp[-(b - a)\xi/4 - (b + a)\mu/4]$ reduces to satisfying $W_{\xi\mu} + \lambda W = 0$, where $\lambda = (a^2 - b^2 + 4c)/16$. If $\lambda \neq 0$, we lose the simple d'Alembert solution. But the equation for W is still easier to handle.

In linear problems discontinuities propagate along characteristics. In nonlinear problems the situation is usually different. The characteristics are often used as new coordinates in the numerical method of characteristics.

Green's Function. Consider the diffusion problem $u_t - u_{xx} = \delta(t)\delta(x - \xi)$, $0 \le x < \infty$, $\xi > 0$, $u(0, t) = 0$, $u(x, 0) = 0$ $[u(\infty, t) = u(\infty, 0) = 0]$, a problem that results from a unit source somewhere in the domain subject to a homogeneous (zero) boundary condition. The solution is called a *Green's function of the first kind.* For this problem there is $G_1(x, \xi, t) = F(x - \xi, t) - F(x + \xi, t)$, where $F(x, t) = e^{-x^2/4t}/\sqrt{4\pi t}$ is the *fundamental* (invariant) *solution.* More generally, the solution of $u_t - u_{xx} = \delta(x - \xi)\,\delta(t - \tau)$, $\xi > 0$, $\tau > 0$, with the same conditions as before, is the Green's function of the first kind.

$$G_1(x, \xi, t - \tau) = \frac{1}{\sqrt{4\pi(t - \tau)}}\left[e^{-(x-\xi)^2/4(t-\tau)} - e^{-(x+\xi)^2/4(t-\tau)}\right]$$

for the semi-infinite interval.

The solution of $u_t - u_{xx} = p(x, t)$, $0 \le x < \infty$, $0 \le t < \infty$, with $u(x, 0) = 0$, $u(0, t) = 0$, $t > 0$ is $u(x, t) = \int_0^t d\tau \int_0^\infty p(\xi, \tau)G_1(x, \xi, t - \tau)]\, d\,\xi$, which is a superposition. Note that the Green's function and the desired solution must both satisfy a zero boundary condition at the origin for this solution to make sense.

The solution of $u_t - u_{xx} = 0$, $0 \le x < \infty$, $0 \le t < \infty$, $u(x, 0) = f(x)$, $u(0, t) = 0$, $t > 0$ is $u(x, t) = \int_0^\infty f(\xi)G_1(x, \xi, t)\, d\,\xi$.

The solution of $u_t - u_{xx} = 0$, $0 \le x < \infty$, $0 \le t < \infty$, $u(x, 0) = 0$, $u(0, t) = g(t)$, $t > 0$ (nonhomogeneous) is obtained by transforming to a new problem that has a homogeneous boundary condition. Thus, with $w(x, t) = u(x, t) - g(t)$ the equation for w becomes $w_t - w_{xx} = -\dot{g}(t) - g(0)\,\delta(t)$ and $w(x, 0) = 0$, $w(0, t) = 0$. Using G_1 above, we finally obtain $u(x, t) = (x/\sqrt{4\pi})\int_0^t g(t - \tau)e^{-x^2/4t}/\tau^{3/2}\, d\tau$.

The Green's function approach can also be employed for elliptic and hyperbolic problems.

Equations in Other Spatial Variables. The sperically symmetric wave equation $u_{rr} + 2u_r/r - u_{tt} = 0$ has the general solution $u(\tau, t) = [f(t - r) + g(t + r)]/r$.

The Poisson-Euler-Darboux equation, arising in gas dynamics,

$$u_{rs} + N(u_r + u_s)/(r + s) = 0$$

where N is a positive integer ≥ 1, has the general solution

$$u(r,s) = k + \frac{\partial^{N-1}}{\partial r^{N-1}}\left[\frac{f(r)}{(r+s)^N}\right] + \frac{\partial^{N-1}}{\partial s^{N-1}}\left[\frac{g(s)}{(r+s)^N}\right]$$

Here, k is an arbitrary constant and f and g are arbitrary functions whose form is determined from the problem initial and boundary conditions.

Conversion to Other Orthogonal Coordinate Systems. Let (x^1, x^2, x^3) be rectangular (Cartesian) coordinates and (u^1, u^2, u^3) be any orthogonal coordinate system related to the rectangular coordinates by $x^i = x^i(u^1, u^2, u^3)$, $i = 1, 2, 3$. With $(ds)^2 = (dx^1)^2 + (dx^2)^2 + (dx^3)^2 = g_{11}(du^1)^2 + g_{22}(du^2)^2 + g_{33}(du^3)^2$, where

$g_{ii} = (\partial x^1/\partial u^i)^2 + (\partial x^2/\partial u^i)^2 + (\partial x^3/\partial u^i)^2$. In terms of these "metric" coefficients the basic operations of applied mathematics are expressible. Thus (with $g = g_{11}g_{22}g_{33}$)

$$dA = \left(g_{11}g_{22}\right)^{1/2}\, du^1\, du^2; \qquad dV = \left(g_{11}g_{22}g_{33}\right)^{1/2}\, du^1\, du^2\, du^3$$

$$\operatorname{grad}\phi = \frac{\vec{a}_1}{\left(g_{11}\right)^{1/2}}\frac{\partial\phi}{\partial u^1} + \frac{\vec{a}_2}{\left(g_{22}\right)^{1/2}}\frac{\partial\phi}{\partial u^2} + \frac{\vec{a}_3}{\left(g_{33}\right)^{1/2}}\frac{\partial\phi}{\partial u^3}$$

($\vec{a}_i$ are unit vectors in direction i);

$$\operatorname{div}\vec{E} = g^{-1/2}\left\{\frac{\partial}{\partial u^1}\left[\left(g_{22}g_{33}\right)^{1/2}E_1\right] + \frac{\partial}{\partial u^2}\left[\left(g_{11}g_{33}\right)^{1/2}E_2\right] + \frac{\partial}{\partial u^3}\left[\left(g_{11}g_{22}\right)^{1/2}E_3\right]\right\}$$

[here $\vec{E} = (E_1, E_2, E_3)$];

$$\begin{aligned}\operatorname{curl}\vec{E} = g^{-1/2}\Bigg\{&\vec{a}_1\left(g_{11}\right)^{1/2}\left(\frac{\partial}{\partial u^2}\left[\left(g_{33}\right)^{1/2}E_3\right] - \frac{\partial}{\partial u^3}\left[\left(g_{22}\right)^{1/2}E_2\right]\right)\\ &+ \vec{a}_2\left(g_{22}\right)^{1/2}\left(\frac{\partial}{\partial u^3}\left[\left(g_{11}\right)^{1/2}E_1\right] - \frac{\partial}{\partial u^1}\left[\left(g_{33}\right)^{1/2}E_3\right]\right)\\ &+ \vec{a}_3\left(g_{33}\right)^{1/2}\left(\frac{\partial}{\partial u^1}\left[\left(g_{22}\right)^{1/2}E_2\right] - \frac{\partial}{\partial u^2}\left[\left(g_{11}\right)^{1/2}E_1\right]\right)\Bigg\}\end{aligned}$$

$$\operatorname{div}\operatorname{grad}\psi = \nabla^2\psi = \text{Laplacian of } \psi = g^{-1/2}\sum_{i=1}^{3}\frac{\partial}{\partial u^i}\left[\frac{g^{1/2}}{g_{ii}}\frac{\partial\psi}{\partial u^i}\right]$$

Table 19.5.2 shows some coordinate systems.

TABLE 19.5.2 Some Coordinate Systems

Coordinate System	Metric Coefficients	
	Circular Cylindrical	
$x = r\cos\theta$	$u^1 = r$	$g_{11} = 1$
$y = r\sin\theta$	$u^2 = \theta$	$g_{22} = r^2$
$z = z$	$u^3 = z$	$g_{33} = 1$
	Spherical	
$x = r\sin\psi\cos\theta$	$u^1 = r$	$g_{11} = 1$
$y = r\sin\psi\sin\theta$	$u^2 = \psi$	$g_{22} = r^2$
$z = r\cos\psi$	$u^3 = \theta$	$g_{33} = r^2\sin^2\psi$
	Parabolic Coordinates	
$x = \mu\nu\cos\theta$	$u^1 = \mu$	$g_{11} = \mu^2 + \nu^2$
$y = \mu\nu\sin\theta$	$u^2 = \nu$	$g_{22} = \mu^2 + \nu^2$
$z = 1/2\,(\mu^2 - \nu^2)$	$u^3 = \theta$	$g_{33} = \mu^2\nu^2$

Other metric coefficients and so forth can be found in Moon and Spencer [1961].

19.6 Integral Equations

William F. Ames

Classification and Notation

Any equation in which the unknown function $u(x)$ appears under the integral sign is called an *integral equation.* If $f(x)$, $K(x, t)$, a, and b are known then the integral equation for u, $\int_a^b K(x, t), u(t)\, dt = f(x)$ is called a *linear integral equation of the first kind of Fredholm type.* $K(x, t)$ is called the *kernel function* of the equation. If b is replaced by x (the independent variable) the equation is an equation of *Volterra type of the first kind.*

An equation of the form $u(x) = f(x) + \lambda \int_a^b K(x, t)u(t)\, dt$ is said to be a linear integral equation of *Fredholm type of the second kind.* If b is replaced by x it is of *Volterra type.* If $f(x)$ is not present the equation is homogeneous.

The equation $\phi(x)\, u(x) = f(x) + \lambda \int_a^{b \text{ or } x} K(x, t)u(t)\, dt$ is the *third kind equation* of Fredholm or Volterra type. If the unknown function u appears in the equation in any way other than to the first power then the integral equation is said to be *nonlinear.* Thus, $u(x) = f(x) + \int_a^b K(x, t) \sin u(t)\, dt$ is nonlinear. An integral equation is said to be *singular* when either or both of the limits of integration are infinite or if $K(x, t)$ becomes infinite at one or more points of the integration interval.

Example 19.6.1. Consider the singular equations $u(x) = x + \int_0^\infty \sin(x\, t)\, u(t)\, dt$ and $f(x) = \int_0^x [u(t)/(x - t)^2]\, dt$.

Relation to Differential Equations

The *Leibnitz rule* $(d/dx)\ \int_{a(x)}^{b(x)} F(x, t)\, dt\ \ \int_{a(x)}^{b(x)} (\partial F/\partial x)\, dt + F[x, b(x)](db/dx) - F[x, a(x)] \times (da/dx)$ is useful for differentiation of an integral involving a parameter (x in this case). With this, one can establish the relation

$$I_n(x) = \int_a^x (x-t)^{n-1} f(t)\, dt = (n-1)! \underbrace{\int_a^x \dots \int_a^x}_{n \text{ times}} f(x)\, \underbrace{dx \dots dx}_{n \text{ times}}$$

This result will be used to establish the relation of the second-order initial value problem to a Volterra integral equation.

The second-order differential equation $y''(x) + A(x)y'(x) + B(x)y = f(x)$, $y(a) = y_0$, $y'(a) = y_0'$ is equivalent to the integral equations

$$y(x) = -\int_a^x \{A(t) + (x-t)[B(t) - A'(t)]\} y(t)\, dt + \int_a^x (x-t) f(t)\, dt + [A(a) y_0 + y_0'](x-a) + y_0$$

which is of the type $(x)y = \int_a^x K(x, t)y(t)\, dt + F(x)$ where $K(x, t) = (t - x)[B(t) - A'(t)] - A(t)$ and $F(x)$ includes the rest of the terms. Thus, this initial value problem is equivalent to a Volterra integral equation of the second kind.

Example 19.6.2. Consider the equation $y'' + x^2y' + xy = x$, $y(0) = 1$, $y'(0) = 0$. Here $A(x) = x^2$, $B(x) = x$, $f(x) = x$, $a = 0$, $y_0 = 1$, $y_0' = 0$. The integral equation is $y(x) = \int_0^x t(x - 2t)y(t)\, dt + (x^3/6) + 1$.

The expression for $I_n(x)$ can also be useful in converting boundary value problems to integral equations. For example, the problem $y''(x) + \lambda y = 0$, $y(0) = 0$, $y(a) = 0$ is equivalent to the Fredholm equation $y(x) = \lambda \int_0^a K(x, t)y(t)\, dt$, where $K(x, t) = (t/a)(a - x)$ when $t < x$ and $K(x, t) = (x/a)(a - t)$ when $t > x$.

In both cases the differential equation can be recovered from the integral equation by using the Leibnitz rule.

Nonlinear differential equations can also be transformed into integral equations. In fact this is one method used to establish properties of the equation and to develop approximate and numerical solutions. For example, the "forced pendulum" equation $y''(x) + a^2 \sin y(x) = f(x)$, $y(0) = y(1) = 0$ transforms into the nonlinear Fredholm equation.

$$y(x) = \int_0^1 K(x,t)\left[a^2 \sin y(t) - f(t)\right] dt$$

with $K(x, t) = x(1 - t)$ for $0 < x < t$ and $K(x, t) = t(1 - x)$ for $t < x < 1$.

Methods of Solution

Only the simplest integral equations can be solved exactly. Usually approximate or numerical methods are employed. The advantage here is that integration is a "smoothing operation," whereas differentiation is a "roughening operation." A few exact and approximate methods are given in the following sections. The numerical methods are found under 19.12.

Convolution Equations

The special convolution equation $y(x) = f(x) + \lambda \int_0^x K(x - t)y(t)\, dt$ is a special case of the Volterra equation of the second kind. $K(x - t)$ is said to be a *convolution kernel.* The integral part is the convolution integral discussed under 19.8. The solution can be accomplished by transforming with the Laplace transform: $L[y(x)] = L[f(x)] + \lambda L[y(x)]L[K(x)]$ or $y(x) = L^{-1}\{L[f(x)]/(1 - \lambda L[K(x)])\}$.

Abel Equation

The Volterra equation $f(x) = \int_0^x y(t)/(x-t)^{\alpha}\, dt$, $0 < \alpha < 1$ is the (singular) Abel equation. Its solution is $y(x) = (\sin \alpha\pi/\pi)(d/dx) \int_0^x F(t)/(x-t)^{1-\alpha} dt$.

Approximate Method (Picard's Method)

This method is one of successive approximations that is described for the equation $y(x) = f(x) + \lambda \int_a^x K(x, t)y(t)\, dt$. Beginning with an initial guess $y_0(t)$ (often the value at the initial point a) generate the next approximation with $y_1(x) = f(x) + \int_a^x K(x, t)y_0(t)\, dt$ and continue with the general iteration

$$y_n(x) = f(x) + \lambda \int_a^x K(x,t) y_{n-1}(t)\, dt$$

Then, by iterating, one studies the convergence of this process, as is described in the literature.

Example 19.6.3. Let $y(x) = 1 + \int_0^x xt[y(t)]^2\, dt$, $y(0) = 1$, With $y_0(t) = 1$ we find $y_1(x) = 1 + \int_0^x xt\, dt = 1 + (x^3/2)$ and $y_2(x) = 1 + \int_0^x xt[1 + (t^3/2)^2 dt$, and so forth.

19.7 Approximation Methods

William F. Ames

The term *approximation methods* usually refers to an analytical process that generates a symbolic approximation rather than a numerical one. Thus, $1 + x + x^2/2$ is an approximation of e^x for small x. This chapter introduces some techniques for approximating the solution of various operator equations.

Perturbation

Regular Perturbation

This procedure is applicable to *some* equations in which a small parameter, ε, appears. Use this procedure with care; the procedure involves expansion of the dependent variables and data in a power series in the small parameter. The following example illustrates the procedure.

Example 19.7.1. Consider the equation $y'' + \varepsilon y' + y = 0$, $y(0) = 1$, $y'(0) = 0$. Write $y(x; \varepsilon) = y_0(x) + \varepsilon y_1(x) + \varepsilon^2 y_2(x) + \cdots$, and the initial conditions (data) become

$$y_0(0) + \varepsilon y_1(0) + \varepsilon^2 y_2(0) + \cdots = 1$$

$$y_0'(0) + \varepsilon y_1'(0) + \varepsilon^2 y_2'(0) + \cdots = 0$$

Equating like powers of ε in all three equations yields the sequence of equations

$$\begin{aligned} &O(\varepsilon^0): y_0'' + y_0 = 0, \qquad && y_0(0) = 1, \qquad && y_0'(0) = 0 \\ &O(\varepsilon^1): y_1'' + y_1 = -y_0', \qquad && y_1(0) = 0, \qquad && y_1'(0) = 0 \\ &\quad\vdots \end{aligned}$$

The solution for y_0 is $y_0 = \cos x$ and using this for y_1 we find $y_1(x) = 1/2\ (\sin x - x\cos x)$. So $y(x;\varepsilon) = \cos x + \varepsilon(\sin\ x - x\cos x)/2 + O(\varepsilon^2)$. Appearance of the term $x\cos x$ indicates a *secular term* that becomes arbitrarily large as $x \to \infty$. Hence, this approximation is valid only for $x \ll 1/\varepsilon$ and for small ε. If an approximation is desired over a larger range of x then the method of multiple scales is required.

Singular Perturbation

The *method of multiple scales* is a singular method that is *sometimes* useful if the regular perturbation method fails. In this case the assumption is made that the solution depends on *two* (or more) different length (or time) scales. By trying various possibilities, one can determine those scales. The scales are treated as dependent variables when transforming the given ordinary differential equation into a partial differential equation, but then the scales are treated as independent variables when solving the equations.

Example 19.7.2. Consider the equation $\varepsilon y'' + y' = 2$, $y(0) = 0$, $y(1) = 1$. This is singular since (with $\varepsilon = 0$) the resulting first-order equation cannot satisfy both boundary conditions. For the problem the proper length scales are $u = x$ and $v = x/\varepsilon$. The second scale can be ascertained by substituting $\varepsilon^n x$ for x and requiring $\varepsilon y''$ and y' to be of the same order in the transformed equation. Then

$$\frac{d}{dx} = \frac{\partial}{\partial u}\frac{du}{dx} + \frac{\partial}{\partial v}\frac{dv}{dx} = \frac{\partial}{\partial u} + \frac{1}{\varepsilon}\frac{\partial}{\partial v}$$

and the equation becomes

$$\varepsilon\left(\frac{\partial}{\partial u} + \frac{1}{\varepsilon}\frac{\partial}{\partial v}\right)^2 y + \left(\frac{\partial}{\partial u} + \frac{1}{\varepsilon}\frac{\partial}{\partial v}\right)y = 2$$

With $y(x;\varepsilon) = y_0(u,v) + \varepsilon y_1(u,v) + \varepsilon^2 y_2(u,v) + \cdots$ we have terms

$$O\left(\varepsilon^{-1}\right): \frac{\partial^2 y_0}{\partial v^2} + \frac{\partial y_0}{\partial v} = 0 \qquad \text{(actually ODEs with parameter } u\text{)}$$

$$O\left(\varepsilon^{0}\right): \frac{\partial^2 y_1}{\partial v^2} + \frac{\partial y_1}{\partial v} = 2 - 2\frac{\partial^2 y_0}{\partial u\partial v} - \frac{\partial y_0}{\partial u}$$

$$O\left(\varepsilon^{1}\right): \frac{\partial^2 y_2}{\partial v^2} + \frac{\partial y_2}{\partial v} = -2\frac{\partial^2 y_1}{\partial u\partial v} - \frac{\partial y_1}{\partial u} - \frac{\partial^2 y_0}{\partial u^2}$$

$$\vdots$$

Then $y_0(u,v) = A(u) + B(u)e^{-v}$ and so the second equation becomes $\partial^2 y_1/\partial v^2 + \partial y_1/\partial v = 2 - A'(u) + B'(u)e^{-v}$, with the solution $y_1(u,v) = [2 - A'(u)]v + vB'(u)e^{-v} + D(u) + E(u)e^{-v}$. Here A, B, D and E are still arbitrary. Now the solvability condition — "higher order terms must vanish no slower (as $\varepsilon \to 0$) than the previous term" (Kevorkian and Cole, 1981) — is used. For y_1 to vanish no slower than y_0 we must have $2 - A'(u) = 0$ and $B'(u) = 0$. If this were not true the terms in y_1 would be larger than those in y_0 ($v \gg 1$). Thus $y_0(u,v) = (2u + A_0) + B_0 e^{-v}$, or in the original variables $y(x;\varepsilon) \approx (2x + A_0) + B_0 e^{-x/\varepsilon}$ and matching to both boundary conditions gives $y(x;\varepsilon) \approx 2x - (1 - e^{-x/\varepsilon})$.

Boundary Layer Method

The boundary layer method is applicable to regions in which the solution is *rapidly varying*. See the references at the end of the chapter for detailed discussion.

Iterative Methods

Taylor Series

If it is known that the solution of a differential equation has a power series in the independent variable (t), then we may proceed from the initial data (the easiest problem) to compute the Taylor series by differentiation.

Example 19.7.3. Consider the equation $(d^2x/dt) = -x - x^2$, $x(0) = 1$, $x'(0) = 1$. From the differential equation, $x''(0) = -2$, and, since $x''' = -x' - 2xx'$, $x'''(0) = -1 - 2 = -3$, so the four term approximation for $x(t) \approx 1 + t - (2t^2/2!) - (3t^3/3!) = 1 + \mathrm{t} - t^2 - t^3/2$. An estimate for the error at $t = t_1$, (see a discussion of series methods in any calculus text) is not greater than $|d^4x/dt^4|_{\max}[(t_1)^4/4!]$, $0 \le t \le t_1$.

Picard's Method

If the vector differential equation $x' = f(t, x)$, $x(0)$ given, is to be approximated by Picard iteration, we begin with an initial guess $\mathrm{x}_0 = \mathrm{x}(0)$ and calculate iteratively $x_i' = f(t, x_{i-1})$.

Example 19.7.4. Consider the equation $x' = x + y^2$, $y' = y - x^3$, $x(0) = 1$, $y(0) = 2$. With $x_0 = 1$, $y_0 = 2$, $x_1' = 5$, $y_1' = 1$, so $x_1 = 5t + 1$, $y_1 = t + 2$, since $x_i(0) = 1$, $y_i(0) = 2$ for $i \ge 0$. To continue, use $x_{i+1}' = x_i + y_i^2$, $y_{i+1}' = y_i - x_i^3$. A modification is the utilization of the first calculated term immediately in the second equation. Thus, the calculated value of $x_1 = 5t + 1$, when used in the second equation, gives $y_1' = y_0 - (5t + 1)^3 = 2 - (125t^3 + 75t^2 + 15t + 1)$, so $y_1 = 2t - (125t^4/4) - 25t^3 - (15t^2/2) - t + 2$. Continue with the iteration $x_{i+1}' = x_i + y_i^3$, $y_{i+1}' = y_i - (x_{i+1})^3$.

Another variation would be $x_{i+1}' = x_{i+1} + (y_i)^3$, $y_{i+1}' = y_{i+1} - (x_{i+1})^3$.

19.8 Integral Transforms

William F. Ames

All of the integral transforms are special cases of the equation $g(s) = \int_a^b K(s, t) f(t)\, d\, t$, in which $g(s)$ is said to be the *transform* of $f(t)$, and $K(s, t)$ is called the *kernel* of the transform. Table 19.8.1 shows the more important kernels and the corresponding intervals (a, b).

Details for the first three transforms listed in Table 19.8.1 are given here. The details for the other are found in the literature.

Laplace Transform

The Laplace transform of $f(t)$ is $g(s) = \int_0^\infty e^{-st} f(t)\, dt$. It may be thought of as transforming one class of functions into another. The advantage in the operation is that under certain circumstances it replaces complicated functions by simpler ones. The notation $L[f(t)] = g(s)$ is called the *direct transform* and

$L^{-1}[g(s)] = f(t)$ is called the *inverse transform*. Both the direct and inverse transforms are tabulated for many often-occurring functions. In general $L^{-1}[g(s)] = (1/2\pi i)\int_{\alpha-i\infty}^{\alpha+i\infty} e^{st}g(s)\,ds$, and to evaluate this integral requires a knowledge of complex variables, the theory of residues, and contour integration.

Properties of the Laplace Transform

Let $L[f(t)] = g(s)$, $L^{-1}[g(s)] = f(t)$.

1. The Laplace transform may be applied to a function $f(t)$ if $f(t)$ is continuous or piecewise continuous; if $t^n|f(t)|$ is finite for all t, $t \to 0$, $n < 1$; and if $e^{-at}|f(t)|$ is finite as $t \to \infty$ for some value of a, $a > 0$.
2. L and L^{-1} are unique.
3. $L[af(t) + bh(t)] = aL[f(t)] + bL[h(t)]$ (linearity).
4. $L[e^{at}f(t)] = g(s - a)$ (shift theorem).
5. $L[(-t)^k f(t)] = d^k g/ds^k$; k a positive integer.

TABLE 19.8.1 Kernels and Intervals of Various Integral Transforms

Name of Transform	(a, b)	$K(s, t)$
Laplace	$(0, \infty)$	e^{-st}
Fourier	$(-\infty, \infty)$	$\frac{1}{\sqrt{2\pi}}e^{-ist}$
Fourier cosine	$(0, \infty)$	$\sqrt{\frac{2}{\pi}}\cos st$
Fourier sine	$(0, \infty)$	$\sqrt{\frac{2}{\pi}}\sin st$
Mellin	$(0, \infty)$	t^{s-1}
Hankel	$(0, \infty)$	$tJ_\nu(st)$, $\nu \geq -\frac{1}{2}$

Example 19.8.1. $L[\sin a\, t] = \int_0^\infty e^{-st}\sin a\, t\, d\, t = a/(s^2 + a^2)$, $s > 0$. By property 5,

$$\int_0^\infty e^{-st}t\sin at\, dt = L[t\sin at] = \frac{2as}{s^2 + a^2}$$

6.
$$\begin{aligned} L[f'(t)] &= sL[f(t)] - f(0) \\ L[f''(t)] &= s^2L[f(t)] - sf(0) - f'(0) \\ &\vdots \\ L\left[f^{(n)}(t)\right] &= s^nL[f(t)] - s^{n-1}f(0) - \cdots - sf^{(n-2)}(0) - f^{(n-1)}(0) \end{aligned}$$

In this property it is apparent that the initial data are automatically brought into the computation.

Example 19.8.2. Solve $y'' + y = e^t$, $y(0) = 1$, $y'(0) = 1$. Now $L[y''] = s^2L[y] - sy(0) - y'(0) = s^2L[y] - s - 1$. Thus, using the linear property of the transform (property 3), $s^2L[y] + L[y] - s - 1 = L[e^t] = 1/(s - 1)$. Therefore, $L[y] = s^2/[(s - 1)(s^2 + 1)]$.

With the notations $\Gamma(n + 1) = \int_0^\infty x^n e^{-x}\,dx$ (gamma function) and $J_n(t)$ the Bessel function of the first kind of order n, a short table of Laplace transforms is given in Table 19.8.2.

7. $L\left[\int_a^t f(t)\,dt\right] = \frac{1}{s}L[f(t)] + \frac{1}{s}\int_a^0 f(t)\,dt.$

TABLE 19.8.2 Some Laplace Transforms

$f(t)$	$g(s)$	$f(t)$	$g(s)$
1	$\frac{1}{s}$	$e^{-at}(1-a\,t)$	$\frac{s}{(s+a)^2}$
t^n, n is a + integer	$\frac{n!}{s^{n+1}}$	$\frac{t\sin at}{2a}$	$\frac{s}{\left(s^2+a^2\right)^2}$
t^n, $n \neq$ a + integer	$\frac{\Gamma(n+1)}{s^{n+1}}$	$\frac{1}{2a^2}\sin at\sinh at$	$\frac{s}{s^4+4a^4}$
$\cos a\,t$	$\frac{s}{s^2+a^2}$	$\cos a\,t\cosh a\,t$	$\frac{s^3}{s^4+4a^4}$
$\sin a\,t$	$\frac{a}{s^2+a^2}$	$\frac{1}{2a}(\sinh at+\sin at)$	$\frac{s^2}{s^4-a^4}$
$\cosh a\,t$	$\frac{s}{s^2-a^2}$	$\frac{1}{2}(\cosh at+\cos at)$	$\frac{s^3}{s^4-a^4}$
$\sinh a\,t$	$\frac{a}{s^2-a^2}$	$\frac{\sin at}{t}$	$\tan^{-1}\frac{a}{s}$
e^{-at}	$\frac{1}{s+a}$	$J_0(a\,t)$	$\frac{1}{\sqrt{s^2+a^2}}$
$e^{-bt}\cos a\,t$	$\frac{s+b}{(s+b)^2+a^2}$	$\frac{n}{a^n}\frac{J_n(at)}{t}$	$\frac{1}{\left(\sqrt{s^2+a^2}+s\right)^n}$
$e^{-bt}\sin a\,t$	$\frac{a}{(s+b)^2+a^2}$	$J_0\left(2\sqrt{at}\right)$	$\frac{1}{s}e^{-a/s}$

Example 19.8.3. Find $f(t)$ if $L[f(t)] = (1/s^2)[1/(s^2-a^2)]$. $L[1/a \sinh a\,t] = 1/(s^2-a^2)$. Therefore, $f(t) = \int_0^t\left[\int_0^t \frac{1}{a}\sinh a\,t\,d\,t\right]d\,t = 1/a^2[(\sinh a\,t)/a - t]$.

$$L\left[\frac{f(t)}{t}\right]=\int_s^\infty g(s)\,ds; \qquad L\left[\frac{f(t)}{t^k}\right]=\underbrace{\int_s^\infty\cdots\int_s^\infty}_{k\text{ integrals}} g(s)(ds)^k$$

Example 19.8.4. $L[(\sin a\,t)/t] = \int_s^\infty L[\sin a\,t)d\,s = \int_s^\infty [a\,d\,s/(s^2+a^2)] = \cot^{-1}(s/a)$.

9. The *unit step function* $u(t-a) = 0$ for $t < a$ and 1 for $t > a$. $L[u(t-a) = e^{-as}/s$.
10. The *unit impulse function* is $\delta(a) = u'(t-a) = 1$ at $t = a$ and 0 elsewhere. $L[u'(t-a) = e^{-as}$.
11. $L^{-1}[e^{-as}g(s)] = f(t-a)u(t-a)$ (second shift theorem).
12. If $f(t)$ is *periodic* of period b — that is, $f(t+b) = f(t)$ — then $L[f(t)] = [1/(1-e^{-bs})] \times \int_0^b e^{-st}f(t)\,dt$.

Example 19.8.5. The equation $\partial^2 y/(\partial t\partial x) + \partial y/\partial t + \partial y/\partial x = 0$ with $(\partial y/\partial x)(0,x) = y(0,x) = 0$ and $y(t,0) + (\partial y/\partial t)(t,0) = \delta(0)$ (see property 10) is solved by using the Laplace transform of y with respect to t. With $g(s,x) = \int_0^\infty e^{-st}y(t,x)\,dt$, the transformed equation becomes

$$s\frac{\partial g}{\partial x}-\frac{\partial y}{\partial x}(0,x)+sg-y(0,x)+\frac{\partial g}{\partial x}=0$$

or

$$(s+1)\frac{\partial g}{\partial x}+sg=\frac{\partial y}{\partial x}(0,x)+y(0,x)=0$$

The second (boundary) condition gives $g(s, 0) + sg(s, 0) - y(0, 0) = 1$ or $g(s, 0) = 1/(1 + s)$. A solution of the preceding ordinary differential equation consistent with this condition is $g(s, x) = [1/(s+1)]e^{-sx/(s+1)}$. Inversion of this transform gives $y(t, x) = e^{-(t+x)}I_0\,(2/\sqrt{tx})$, where I_0 is the zero-order Bessel function of an imaginary argument.

Convolution Integral

The *convolution integral* (*faltung*) of two functions $f(t)$, $r(t)$ is $x(t) = f(t)*r(t) = \int_0^t f(\tau)r(t-\tau)\,d\tau$.

Example 19.8.6. $t * \sin t = \int_0^t \tau \sin(t-\tau)\,d\tau = t - \sin t$.

13. $L[f(t)]L[h(t)] = L[f(t) * h(t)]$.

Fourier Transform

The *Fourier transform* is given by $F[f(t)] = (1/\sqrt{2\pi})\int_{-\infty}^{\infty} f(t)e^{-ist}\,d\,t = g(s)$ and its *inverse* by $F^{-1}[g(s)] = (1/\sqrt{2\pi})\int_{-\infty}^{\infty} g(s)e^{ist}\,d\,t = f(t)$. In brief, the condition for the Fourier transform to exist is that $\int_{-\infty}^{\infty} |f(t)|\,d\,t < \infty$, although certain functions may have a Fourier transform even if this is violated.

Example 19.8.7. The function $f(t) = 1$ for $-a \le t \le a$ and $= 0$ elsewhere has

$$F[f(t)] = \int_{-a}^{a} e^{-ist}\,dt = \int_0^a e^{ist}\,dt + \int_0^a e^{-ist}\,dt = 2\int_0^a \cos st\,dt = \frac{2\sin sa}{s}$$

Properties of the Fourier Transform

Let $F[f(t)] = g(s)$; $F^{-1}[g(s)] = f(t)$.

1. $F[f^{(n)}(t)] = (i\,s)^n\,F[f(t)]$
2. $F[af(t) + bh(t)] = aF[f(t)] + bF[h(t)]$
3. $F[f(-t)] = g(-s)$
4. $F[f(at)] = 1/a\;g(s/a), \quad a > 0$
5. $F[e^{-iwt}f(t)] = g(s + w)$
6. $F[f(t + t_1)] = e^{ist_1}g(s)$
7. $F[f(t)] = G(i\,s) + G(-i\,s)$ if $f(t) = f(-t)(f(t)$ even)
   $F[f(t)] = G(i\,s) - G(-i\,s)$ if $f(t) = -f(-t)(f$ odd)

where $G(s) = L[f(t)]$. This result allows the use of the Laplace transform tables to obtain the Fourier transforms.

Example 19.8.8. Find $F[e^{-a|t|}]$ by property 7. The term $e^{-a|t|}$ is even. So $L[e^{-at}] = 1/(s + a)$. Therefore, $F[e^{-a|t|}] = 1/(i\,s + a) + 1/(-i\,s + a) = 2a/(s^2 + a^2)$.

Fourier Cosine Transform

The *Fourier cosine transform* is given by $F_c[f(t)] = g(s) = \sqrt{(2/\pi)}\int_0^{\infty} f(t)\cos s\,t\,d\,t$ and its *inverse* by $F_c^{-1}[g(s)] = f(t) = \sqrt{(2/\pi)}\int_0^{\infty} g(s)\cos s\,t\,d\,s$. The *Fourier sine transform* F_s is obtainable by replacing the cosine by the sine in the above integrals.

Example 19.8.9. $F_c[f(t)]$, $f(t) = 1$ for $0 < t < a$ and 0 for $a < t < \infty$. $F_c\,[f(t)] = \sqrt{(2/\pi)}\int_0^a \cos s\,t\,d\,t = \sqrt{(2/\pi)}\,(\sin a\,s)/s$.

Properties of the Fourier Cosine Transform

$F_c[f(t)] = g(s)$.

1. $F_c[af(t) + bh(t)] = aF_c[f(t)] + bF_c[h(t)]$
2. $F_c[f(at)] = (1/a)\, g\,(s/a)$
3. $F_c[f(at) \cos bt] = 1/2a\, [g\,((s + b)/a) + g((s - b)/a)],\ a, b > 0$
4. $F_c[t^{2n}f(t)] = (-1)^n(d^{2n}g)/(d\, s^{2n})$
5. $F_c[t^{2n+1}f(t)] = (-1)^n(d^{2n+1})/(d\, s^{2n+1})\ F_s[f(t)]$

Table 19.8.3 presents some Fourier cosine transforms.

TABLE 19.8.3 Fourier Cosine Transforms

$f(t)$	$\dfrac{g(s)}{\sqrt{2/\pi}}$
$\left.\begin{array}{ll} t & 0<t<1 \\ 2-t & 1<t<2 \\ 0 & 2<t<\infty \end{array}\right\}$	$\frac{1}{s^2}[2\cos s - 1 - \cos 2s]$
$t^{-1/2}$	$\pi^{1/2}(s)^{-1/2}$
$\left.\begin{array}{ll} 0 & 0<t<a \\ (t-a)^{-1/2} & a<t<\infty \end{array}\right\}$	$\pi^{1/2}(s)^{-1/2}\ [\cos a\, s - \sin a\, s]$
$(t^2 + a^2)^{-1}$	$\frac{1}{2}\pi a^{-1}e^{-as}$
$e^{-at},\quad a > 0$	$\dfrac{a}{s^2 + a^2}$
$e^{-at^2},\quad a > 0$	$\frac{1}{2}\pi^{1/2}a^{-1/2}e^{-s^2/4a}$
$\dfrac{\sin at}{t}\quad a > 0$	$\begin{cases} \pi/2 & s<a \\ \pi/4 & s=a \\ 0 & s>a \end{cases}$

Example 19.8.10. The temperature θ in the semiinfinite rod $0 \le x < \infty$ is determined by the differential equation $\partial\theta/\partial t = k(\partial^2\theta/\partial x^2)$ and the condition $\theta = 0$ when $t = 0, x \ge 0$; $\partial\theta/\partial x = -\mu$ = constant when $x = 0, t > 0$. By using the Fourier cosine transform, a solution may be found as $\theta(x, t) = (2\mu/\pi) \int_0^\infty (\cos px/p)\,(1 - e^{-kp2t})\ d\,p$.

19.9 Calculus of Variations

William F. Ames

The basic problem in the *calculus of variations* is to determine a function such that a certain *functional*, often an integral involving that function and certain of its derivatives, takes on *maximum or minimum values.* As an example, find the function $y(x)$ such that $y(x_1) = y_1$, $y(x_2) = y_2$ and the integral (functional) $I = 2\pi \int_{x_1}^{x_2} y[1 + y')^2]^{1/2}\, d\, x$ is a minimum. A second example concerns the transverse deformation $u(x, t)$ of a beam. The energy functional $I = \int_{t_1}^{t_2} \int_0^L [1/2\ \rho\ (\partial u/\partial t)^2 - 1/2\ EI\ (\partial^2 u/\partial x^2)^2 + fu]\ d\ x\ d\ t$ is to be minimized.

The Euler Equation

The elementary part of the theory is concerned with a *necessary* condition (generally in the form of a differential equation with boundary conditions) that the required function must satisfy. To show mathematically that the function obtained actually maximizes (or minimizes) the integral is much more difficult than the corresponding problems of the differential calculus.

The *simplest case* is to determine a function $y(x)$ that makes the integral $I = \int_{x_1}^{x_2} F(x, y, y')\, dx$ stationary and that satisfies the prescribed end conditions $y(x_1) = y_1$ and $y(x_2) = y_2$. Here we suppose F has continuous second partial derivatives with respect to x, y, and $y' = dy/dx$. If $y(x)$ is such a function, then it must satisfy the *Euler equation* $(d/dx)(\partial F/\partial y') - (\partial F/\partial y) = 0$, which is the required necessary condition. The indicated partial derivatives have been formed by treating x, y, and y' as independent variables. Expanding the equation, the equivalent form $F_{y'y'}y'' + F_{y'y}y' + (F_{y'x} - F_y) = 0$ is found. This is second order in y unless $F_{y'y'} = (\partial^2 F)/[(\partial y')^2] = 0$. An alternative form $1/y'[d/dx(F - (\partial F/\partial y')(dy/dx)) - (\partial F/\partial x)] = 0$ is useful. Clearly, if F does not involve x explicitly $[(\partial F/\partial x) = 0]$ a first integral of Euler's equation is $F - y'(\partial F/\partial y') = c$. If F does not involve y explicitly $[(\partial F/\partial y) = 0]$ a first integral is $(\partial F/\partial y') = c$.

The Euler equation for $I = 2\pi \int_{x_1}^{x_2} y[1 + (y')^2]^{1/2}\, dx$, $y(x_1) = y_1$, $y(x_2) = y_2$ is $(d/dx)[yy'/[1 + (y')^2]^{1/2}] - [1 + (y')^2]^{1/2} = 0$ or after reduction $yy'' - (y')^2 - 1 = 0$. The solution is $y = c_1 \cosh(x/c_1 + c_2)$, where c_1 and c_2 are integration constants. Thus the required minimal surface, if it exists, must be obtained by revolving a catenary. Can c_1 and c_2 be chosen so that the solution passes through the assigned points? The answer is found in the solution of a transcendental equation that has two, one, or no solutions, depending on the prescribed values of y_1 and y_2.

The Variation

If $F = F(x, y, y')$, with x independent and $y = y(x)$, then the *first variation* δF of F is defined to be $\delta F = (\partial F/\partial x)\ \delta y + (\partial F/\partial y)\ \delta y'$ and $\delta y' = \delta\ (dy/dx) = (d/dx)\ (\delta y)$ — that is, they commute. Note that the first variation, δF, of a functional is a first-order change from curve to curve, whereas the differential of a function is a first-order approximation to the change in that function along a *particular curve.* The laws of δ are as follows: $\delta(c_1 F + c_2 G) = c_1 \delta F + c_2 \delta G$; $\delta(FG) = F\delta G + G\delta F$; $\delta(F/G) = (G\delta F - F\delta G)/G^2$; if x is an independent variable, $\delta x = 0$; if $u = u(x, y)$; $(\partial/\partial x)(\delta u) = \delta(\partial u/\partial x)$, $(\partial/\partial y)\ (\delta u) = \delta(\partial u/\partial y)$.

A necessary condition that the integral $I = \int_{x_1}^{x_2} F(x, y, y')\, dx$ be stationary is that its (first) variation vanish — that is, $\delta I = \delta \int_{x_1}^{x_2} F(x, y, y')\, dx = 0$. Carrying out the variation and integrating by parts yields of $\delta I = \int_{x_1}^{x_2} [(\partial F/\partial y) - (d/dx)(\partial F/\partial y')]\ \delta y\, dx + [(\partial F/\partial y')\ \partial y]_{x_1}^{x_2} = 0$. The arbitrary nature of δy means the square bracket must vanish and the last term constitutes the *natural boundary conditions.*

Example. The *Euler equation* of $\int_{x_1}^{x_2} F(x, y, y', y'')\, dx$ is $(d^2/dx^2)(\partial F/\partial y'') - (d/dx)(\partial F/\partial y') + (\partial F/\partial y) = 0$, with natural boundary conditions $\{[(d/dx)(\partial F/\partial y'') - (\partial F/\partial y')]\ \delta y\}_{x_1}^{x_2} = 0$ and $(\partial F/\partial y'')\ \delta y'|_{x_1}^{x_2} = 0$. The Euler equation of $\int_{x_1}^{x_2} \int_{y_1}^{y_2} F(x, y, u, u_x, u_y, u_{xx}, u_{xy}, u_{yy})\, dx\, dy$ is $(\partial^2/\partial x^2)(\partial F/\partial u_{xx}) + (\partial^2/\partial x \partial y)(\partial F/u_{xy}) + (\partial^2/\partial y^2)(\partial F/\partial u_{yy}) - (\partial/\partial x)(\partial F/\partial u_x) - (\partial/\partial y)(\partial F/\partial u_y) + (\partial F/\partial u)$, and the natural boundary conditions are

$$\left[\left(\frac{\partial}{\partial x}\left(\frac{\partial F}{\partial u_{xx}}\right)+\frac{\partial}{\partial y}\left(\frac{\partial F}{\partial u_{xy}}\right)-\frac{\partial F}{\partial u_x}\right)\delta u\right]_{x_1}^{x_2}=0, \qquad \left[\left(\frac{\partial F}{\partial u_{xx}}\right)\delta u_x\right]_{x_1}^{x_2}=0$$

$$\left[\left(\frac{\partial}{\partial y}\left(\frac{\partial F}{\partial u_{yy}}\right)+\frac{\partial}{\partial x}\left(\frac{\partial F}{\partial u_{xy}}\right)-\frac{\partial F}{\partial u_y}\right)\delta u\right]_{y_1}^{y_2}=0, \qquad \left[\left(\frac{\partial F}{\partial u_{yy}}\right)\delta u_y\right]_{y_1}^{y_2}=0$$

In the more general case of $I = \iint_R F(x, y, u, v, u_x, u_y, v_x, v_y)\, dx\, dy$, the condition $\delta I = 0$ gives rise to the two Euler equations $(\partial/\partial x)(\partial F/\partial u_x) + (\partial/\partial y)(\partial F/\partial u_y) - (\partial F/\partial u) = 0$ and $(\partial/\partial x)(\partial F/\partial v_x) + (\partial/\partial y)(\partial F/\partial v_y) - (\partial F/\partial v) = 0$. These are two PDEs in u and v that are linear or quasi-linear in u and v. The Euler equation for $I = \iiint_R (u_x^2 + u_y^2 + u_z^2)\, dx\, dy\, dz$, from $\delta I = 0$, is Laplace's equation $u_{xx} + u_{yy} + u_{zz} = 0$.

Variational problems are easily derived from the differential equation and associated boundary conditions by multiplying by the variation and integrating the appropriate number of times. To illustrate, let $F(x)$, $\rho(x)$, $p(x)$, and w be the tension, the linear mass density, the natural load, and (constant) angular velocity of a rotating string of length L. The equation of motion is $(d/dx)[F\,(dy/dx)] + \rho w^2 y + p = 0$. To formulate a corresponding variational problem, multiply all terms by a variation δy and integrate over $(0, L)$ to obtain

$$\int_0^L \frac{d}{dx}\left(F\frac{dy}{dx}\right)\delta y\, dx + \int_0^L \rho w^2 y \delta y\, dx + \int_0^L p\delta y\, dx = 0$$

The second and third integrals are the variations of 1/2 $\rho w^2 y^2$ and py, respectively. To treat the first integral, integrate by parts to obtain

$$\left[F\frac{dy}{dx}\delta y\right]_0^L - \int_0^L F\frac{dy}{dx}\delta\frac{dy}{dx}\, dx = \left[F\frac{dy}{dx}\delta y\right]_0^L - \int_0^L \frac{1}{2}F\delta\left(\frac{dy}{dx}\right)^2 dx = 0$$

So the variation formulation is

$$\delta\int_0^L\left[\frac{1}{2}\rho w^2 y^2 + py - \frac{1}{2}F\left(\frac{dy}{dx}\right)^2\right]dx + \left[F\frac{dy}{dx}\delta y\right]_0^L = 0$$

The last term represents the *natural boundary conditions*. The term 1/2 $\rho w^2 y^2$ is the kinetic energy per unit length, the term $-py$ is the potential energy per unit length due to the radial force $p(x)$, and the term 1/2 $F(dy/dx)^2$ is a first approximation to the potential energy per unit length due to the tension $F(x)$ in the string. Thus the integral is often called the *energy integral*.

Constraints

The variations in some cases cannot be arbitrarily assigned because of one or more auxiliary conditions that are usually called *constraints*. A typical case is the functional $\int_{x_1}^{x_2} F(x, u, v, u_x, v_x)\, dx$ with a constraint $\phi(u, v) = 0$ relating u and v. If the variations of u and v (δu and δv) vanish at the end points, then the variation of the integral becomes

$$\int_{x_1}^{x_2}\left\{\left[\frac{\partial F}{\partial u} - \frac{d}{dx}\left(\frac{\partial F}{\partial u_x}\right)\right]\delta u + \left[\frac{\partial F}{\partial v} - \frac{d}{dx}\left(\frac{\partial F}{\partial v_x}\right)\right]\delta v\right\}dx = 0$$

The variation of the constraint $\phi(u, v) = 0$, $\phi_u\delta u + \phi_v\delta v = 0$ means that the variations cannot both be assigned arbitrarily inside (x_1, x_2), so their coefficients need not vanish separately. Multiply $\phi_u\delta u + \phi_v\delta v = 0$ by a Lagrange multiplier λ (may be a function of x) and integrate to find $\int_{x_1}^{x_2} (\lambda\phi_u\delta u + \lambda\phi_v\delta v)\, dx = 0$. Adding this to the previous result yields

$$\int_{x_1}^{x_2} \left\{ \left[\frac{\partial F}{\partial u} - \frac{d}{dx}\left(\frac{\partial F}{\partial u_x} \right) + \lambda\phi_u \right] \delta u + \left[\frac{\partial F}{\partial v} - \frac{d}{dx}\left(\frac{\partial F}{\partial v_x} \right) + \lambda\phi_v \right] \delta v \right\} dx = 0$$

which must hold for any λ. Assign λ so the first square bracket vanishes. Then δv can be assigned to vanish inside (x_1, x_2) so the two systems

$$\frac{d}{dx}\left[\frac{\partial F}{\partial u_x} \right] - \frac{\partial F}{\partial u} - \lambda\phi_u = 0, \qquad \frac{d}{dx}\left[\frac{\partial F}{\partial v_x} \right] - \frac{\partial F}{\partial v} - \lambda\phi_v = 0$$

plus the constraint $\phi(u, v) = 0$ are three equations for u, v and λ.

19.10 Optimization Methods

George Cain

Linear Programming

Let **A** be an $m \times n$ matrix, **b** a column vector with m components, and **c** a column vector with n components. Suppose $m < n$, and assume the rank of **A** is m. The standard linear programming problem is to find, among all nonnegative solutions of **Ax** = **b**, one that minimizes

$$\mathbf{c}^{\mathrm{T}}\mathbf{x} = c_1 x_1 + c_2 x_2 + \cdots + c_n x_n$$

This problem is called a *linear* program. Each solution of the system **Ax** = **b** is called a *feasible* solution, and the *feasible set* is the collection of all *feasible solutions.* The function $\mathbf{c}^{\mathrm{T}}\mathbf{x} = c_1x_1 + c_2x_2 + \cdots + c_nx_n$ is the cost function, or the objective function. A solution to the linear program is called an *optimal feasible solution.*

Let **B** be an $m \times n$ submatrix of **A** made up of m linearly independent columns of **A**, and let **C** be the $m \times (n - m)$ matrix made up of the remaining columns of **A**. Let $\mathbf{x_B}$ be the vector consisting of the components of **x** corresponding to the columns of **A** that make up **B**, and let $\mathbf{x_C}$ be the vector of the remaining components of **x**, that is, the components of **x** that correspond to the columns of **C**. Then the equation **Ax** = **b** may be written $\mathbf{Bx_B} + \mathbf{Cx_C} = \mathbf{b}$. A solution of $\mathbf{Bx_B} = \mathbf{b}$ together with $\mathbf{x_C} = \mathbf{0}$ gives a solution **x** of the system **Ax** = **b**. Such a solution is called a *basic solution,* and if it is, in addition, nonnegative, it is a *basic feasible solution*. If it is also optimal, it is an *optimal basic feasible solution*. The components of a basic solution are called *basic variables*.

The Fundamental Theorem of Linear Programming says that if there is a feasible solution, there is a basic feasible solution, and if there is an optimal feasible solution, there is an optimal basic feasible solution. The linear programming problem is thus reduced to searching among the set of basic solutions for an optimal solution. This set is, of course, finite, containing as many as $n!/[m!(n - m)!]$ points. In practice, this will be a very large number, making it imperative that one use some efficient search procedure in seeking an optimal solution. The most important of such procedures is the *simplex method*, details of which may be found in the references.

The problem of finding a solution of $\mathbf{Ax} \le \mathbf{b}$ that minimizes $\mathbf{c}^T\mathbf{x}$ can be reduced to the standard problem by appending to the vector $\mathbf{x}$ an additional m nonnegative components, called *slack variables*. The vector $\mathbf{x}$ is replaced by $\mathbf{z}$, where $\mathbf{z}^T = [x_1, x_2 \ldots x_n \; s_1, s_2 \ldots x_m]$, and the matrix $\mathbf{A}$ is replaced by $\mathbf{B} = [\mathbf{A}\ \mathbf{I}]$, where $\mathbf{I}$ is the $m \times m$ identity matrix. The equation $\mathbf{Ax} = \mathbf{b}$ is thus replaced by $\mathbf{Bz} = \mathbf{Ax} + s = \mathbf{b}$, where $s^T = [s_1, s_2, \ldots, s_m]$. Similarly, if inequalities are reversed so that we have $\mathbf{Ax} \le \mathbf{b}$, we simply append $-s$ to the vector x. In this case, the additional variables are called *surplus variables*.

Associated with every linear programming problem is a corresponding dual problem. If the *primal* problem is to minimize $\mathbf{c}^T\mathbf{x}$ subject to $\mathbf{Ax} \ge \mathbf{b}$, and $\mathbf{x} \ge 0$, the corresponding *dual* problem is to maximize $\mathbf{y}^T\mathbf{b}$ subject to $\mathbf{t}^T\mathbf{A} \le \mathbf{c}^T$. If either the primal problem or the dual problem has an optimal solution, so also does the other. Moreover, if $\mathbf{x_p}$ is an optimal solution for the primal problem and $\mathbf{y_d}$ is an optimal solution for the corresponding dual problem $\mathbf{c}^T\mathbf{x_p} = \mathbf{y_d^T b}$.

Unconstrained Nonlinear Programming

The problem of minimizing or maximizing a sufficiently smooth nonlinear function $f(x)$ of n variables, $\mathbf{x}^T = [x_1, x_2 \ldots x_n]$, with no restrictions on x is essentially an ordinary problem in calculus. At a minimizer or maximizer x^*, it must be true that the gradient of f vanishes:

$$\nabla f\left(\mathbf{x}^*\right) = 0$$

Thus x^* will be in the set of all solutions of this system of n generally nonlinear equations. The solution of the system can be, of course, a nontrivial undertaking. There are many recipes for solving systems of nonlinear equations. A method specifically designed for minimizing f is the *method of steepest descent*. It is an old and honorable algorithm, and the one on which most other more complicated algorithms for unconstrained optimization are based. The method is based on the fact that at any point x, the direction of maximum decrease of f is in the direction of $-\nabla f(x)$. The algorithm searches in this direction for a minimum, recomputes $\nabla f(x)$ at this point, and continues iteratively. Explicitly:

1. Choose an initial point x_0.
2. Assume x_k has been computed; then compute $y_k = \nabla f(x_k)$, and let $t_k \ge 0$ be a local minimum of $g(t) = f(x_k - ty_k)$. Then $x_{k+1} = x_k - t_k y_k$.
3. Replace k by $k + 1$, and repeat step 2 until t_k is small enough.

Under reasonably general conditions, the sequence (x_k) converges to a minimum of f.

Constrained Nonlinear Programming

The problem of finding the maximum or minimum of a function $f(x)$ of n variables, subject to the constraints

$$\mathbf{a}(\mathbf{x}) = \begin{bmatrix} a_1(x_1, x_2, \ldots, x_n) \\ a_2(x_1, x_2, \ldots, x_n) \\ \vdots \\ a_m(x_1, x_2, \ldots, x_n) \end{bmatrix} = \begin{bmatrix} b_1 \\ b \\ \vdots \\ b_m \end{bmatrix} = \mathbf{b}$$

is made into an unconstrained problem by introducing the new function $L(x)$:

$$L(\mathbf{x}) = f(\mathbf{x}) + \mathbf{z}^{\mathrm{T}}\mathbf{a}(\mathbf{x})$$

where $\mathbf{z}^{\mathrm{T}} = [\lambda_1, \lambda_2, \ldots, \lambda_m]$ is the vector of *Lagrange multipliers.* Now the requirement that $\nabla L(x) = 0$, together with the constraints $\mathrm{a}(\mathrm{x}) = \mathbf{b}$, give a system of $n + m$ equations

$$\nabla f(\mathbf{x}) + \mathbf{z}^{\mathrm{T}}\nabla\mathbf{a}(\mathbf{x}) = 0$$

$$\mathbf{a}(\mathbf{x}) = \mathbf{b}$$

for the $n + m$ unknowns $x_1, x_2 \ldots, x_n, \lambda_1\lambda_2 \ldots, \lambda_m$ that must be satisfied by the minimizer (or maximizer) x.

The problem of inequality constraints is significantly more complicated in the nonlinear case than in the linear case. Consider the problem of minimizing $f(x)$ subject to m equality constraints $\mathbf{a}(\mathbf{x}) = \mathbf{b}$, and p inequality constraints $\mathrm{c}(\mathrm{x}) \le \mathbf{d}$ [thus $\mathbf{a}(\mathbf{x})$ and $\mathbf{b}$ are vectors of m components, and $\mathrm{c}(\mathrm{x})$ and $\mathbf{d}$ are vectors of p components.] A point x^* that satisfies the constraints is a *regular point* if the collection

$$\left\{\nabla a_1(\mathbf{x}^*), \nabla a_2(\mathbf{x}^*), \ldots, \nabla a_m(\mathbf{x}^*)\right\} \cup \left\{\nabla c_j(\mathbf{x}^*) : j \in J\right\}$$

where

$$J = \left\{j : c_j(\mathbf{x}^*) = d_j\right\}$$

is linearly independent. If x^* is a local minimum for the constrained problem and if it is a regular point, there is a vector $\boldsymbol{z}$ with m components and a vector $\mathbf{w} \ge \mathbf{0}$ with p components such that

$$\nabla f(\mathbf{x}^*) + \mathbf{z}^{\mathrm{T}}\nabla\mathbf{a}(\mathbf{x}^*) + \mathbf{w}^{\mathrm{T}}\nabla\mathbf{c}(\mathbf{x}^*) = 0$$

$$\mathbf{w}^{\mathrm{T}}\left(\mathbf{c}(\mathbf{x}^*) - \mathbf{d}\right) = 0$$

These are the *Kuhn-Tucker conditions.* Note that in order to solve these equations, one needs to know for which j it is true that $c_j(\mathrm{x}^*) = 0$. (Such a constraint is said to be *active.*)

19.11 Engineering Statistics

Y. L. Tong

Introduction

In most engineering experiments, the outcomes (and hence the observed data) appear in a random and on deterministic fashion. For example, the operating time of a system before failure, the tensile strength of a certain type of material, and the number of defective items in a batch of items produced are all subject to random variations from one experiment to another. In engineering statistics, we apply the theory and methods of statistics to develop procedures for summarizing the data and making statistical inferences, thus obtaining useful information with the presence of randomness and uncertainty.

Elementary Probability

Random Variables and Probability Distributions

Intuitively speaking, a random variable (denoted by X, Y, Z, etc.) takes a numerical value that depends on the outcome of the experiment. Since the outcome of an experiment is subject to random variation, the resulting numerical value is also random. In order to provide a stochastic model for describing the probability distribution of a random variable X, we generally classify random variables into two groups: the discrete type and the continuous type. The discrete random variables are those which, technically speaking, take a finite number or a countably infinite number of possible numerical values. (In most engineering applications they take nonnegative integer values.) Continuous random variables involve outcome variables such as time, length or distance, area, and volume. We specify a function $f(x)$, called the probability density function (p.d.f.) of a random variable X, such that the random variable X takes a value in a set A (or real numbers) as given by

$$P[X \in A] = \begin{cases} \sum_{x \in A} f(x) & \text{for all sets } A \text{ if } X \text{ is discrete} \\ \int_A f(x)\,dx & \text{for all intervals } A \text{ if } X \text{ is continuous} \end{cases} \tag{9.11.1}$$

By letting A be the set of all values that are less than or equal to a fixed number t, i.e., $A = (-\infty, t)$, the probability function $P[X \le t]$, denoted by $F(t)$, is called the distribution function of X. We note that, by calculus, if X is a continuous random variable and if $F(x)$ is differentiable, then $f(x) = \frac{d}{dx} F(x)$.

Expectations

In many applications the "payoff" or "reward" of an experiment with a numerical outcome X is a specific function of X ($u(X)$, say). Since X is a random variable, $u(X)$ is also a random variable. We define the expected value of $u(X)$ by

$$Eu(X) = \begin{cases} \sum_x u(x) f(x) & \text{if } X \text{ is discrete} \\ \int_{-\infty}^{\infty} u(x) f(x)\,dx & \text{if } X \text{ is continuous} \end{cases} \tag{9.11.12}$$

provided of course, that, the sum or the integral exists. In particular, if $u(x) = x$, the $EX \equiv \mu$ is called the mean of X (of the distribution) and $E(X - \mu)^2 \equiv \sigma^2$ is called the variance of X (of the distribution). The mean is a measurement of the central tendency, and the variance is a measurement of the dispersion of the distribution.

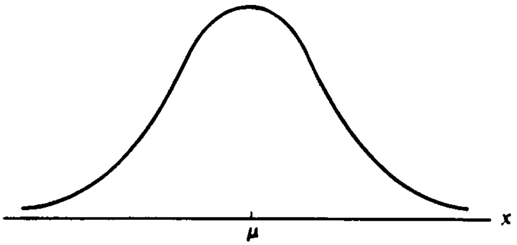

FIGURE 19.11.1 The normal curve with mean μ and variance σ^2.

Some Commonly Used Distributions

Many well-known distributions are useful in engineering statistics. Among the discrete distributions, the hypergeometric and binomial distributions have applications in acceptance sampling problems and quality control, and the Poisson distribution is useful for studying queuing theory and other related problems. Among the continuous distributions, the uniform distribution concerns random numbers and can be applied in simulation studies, the exponential and gamma distributions are closely related to the Poisson distribution, and they, together with the Weibull distribution, have important applications in life testing and reliability studies. All of these distributions involve some unknown parameter(s), hence their means and variances also depend on the parameter(s). The reader is referred to textbooks in this area for details. For example, Hahn and Shapiro (1967, pp. 163–169 and pp. 120–134) contains a comprehensive listing of these and other distributions on their p.d.f.'s and the graphs, parameter(s), means, variances, with discussions and examples of their applications.

The Normal Distribution

Perhaps *the* most important distribution in statistics and probability is the normal distribution (also known as the Gaussian distribution). This distribution involves two parameters: μ and σ^2, and its p.d.f. is given by

$$f(x) = f\left(x;\mu,\sigma^2\right) = \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{1}{2\sigma^2}(x-\mu)^2} \qquad (9.11.3)$$

for $-\infty < \mu < \infty$, $\sigma^2 > 0$, and $-\infty < \chi < \infty$. It can be shown analytically that, for a p.d.f. of this form, the values of μ and σ^2 are, respectively, that of the mean and the variance of the distribution. Further, the quantity, $\sigma = \sqrt{\sigma^2}$ is called the standard deviation of the distribution. We shall use the symbol $X \sim N(\mu, \sigma^2)$ to denote that X has a normal distribution with mean μ and variance σ^2. When plottting the p.d.f. $f(x; \mu, \sigma^2)$ given in Equation (19.11.3) we see that the resulting graph represents a bell-shaped curve symmetric about μ, as shown in Figure 19.11.1.

If a random variable Z has an $N(0,1)$ distribution, then the p.d.f. of Z is given by (from Equation (19.11.3))

$$\phi(z) = \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}x^2} \qquad -\infty < z < \infty \qquad (9.11.4)$$

The distribution function of Z,

$$\Phi(z) = \int_{-\infty}^{x} \phi(u)\, du \qquad -\infty < z < \infty \qquad (9.11.5)$$

cannot be given in a closed form, hence it has been tabulated. The table of $\Phi(z)$ can be found in most textbooks in statistics and probability, including those listed in the references at the end of this section. (We note in passing that, by the symmetry property, $\Phi(z) + \Phi(-z) = 1$ holds for all z.)

Random Sample and Sampling Distributions

Random Sample and Related Statistics

As noted in Box et al. (1978), the design and analysis of engineering experiments usually involves the following steps:

1. The choice of a suitable stochastic model by assuming that the observations follow a certain distribution. The functional form of the distribution (or the p.d.f.) is assumed to be known, except the value(s) of the parameters(s).
2. Design of experiments and collection of data.
3. Summarization of data and computation of certain statistics.
4. Statistical inference (including the estimation of the parameters of the underlying distribution and the hypothesis-testing problems).

In order to make statistical inference concerning the parameter(s) of a distribution, it is essential to first study the sampling distributions. We say that $X_1, X_2, \ldots, X_n$ represent a random sample of size n if they are independent random variables and each of them has the same p.d.f., $f(x)$. (Due to space limitations, the notion of independence will not be carefully discussed here. Nevertheless, we say that $X_1, X_2, \ldots, X_n$ are independent if

$$P\left[X_1 \in A_1, X_2 \in A_2, \ldots, X_n \in A_n\right] = \prod_{i=1}^{n} P\left[X_i \in A_i\right] \tag{19.11.6}$$

holds for all sets $A_1, A_2, \ldots, A_n$.) Since the parameter(s) of the population is (are) unknown, the population mean μ and the population variance σ^2 are unknown. In most commonly used distributions μ and σ^2 can be estimated by the sample mean $\bar{X}$ and the sample variance S^2, respectively, which are given by

$$\bar{X} = \frac{1}{n}\sum_{i=1}^{n} X_i, \qquad S^2 = \frac{1}{n-1}\sum_{i=1}^{n}\left(X_i - \bar{X}\right)^2 = \frac{1}{n-1}\left[\sum_{i=1}^{n} X_i^2 - n\bar{X}^2\right] \tag{19.11.7}$$

(The second equality in the formula for S^2 can be verified algebraically.) Now, since $X_1, X_2, \ldots, X_n$ are random variables $\bar{X}$ and S^2 are also random variables. Each of them is called a statistic and has a probability distribution which also involves the unknown parameter(s). In probability theory there are two fundamental results concerning their distributional properties.

Theorem 1. (Weak Law of Large Numbers). As the sample size n becomes large, $\bar{X}$ converges to μ in probability and S^2 converges to σ^2 in probability. More precisely, for every fixed positive number $\varepsilon > 0$ we have

$$P\left[\left|\bar{X} - \mu\right| \le \varepsilon\right] \to 1, \qquad P\left[\left|S^2 - \sigma^2\right| \le \varepsilon\right] \to 1 \tag{19.11.8}$$

as $n \to \infty$.

Theorem 2. (Central Limit Theorem). As n becomes large, the distribution of the random variable

$$Z = \frac{\bar{X} - \mu}{\sigma \sqrt{n}} = \frac{\sqrt{n}\left(\bar{X} - \mu\right)}{\sigma} \tag{19.11.9}$$

has approximately an $N(0,1)$ distribution. More precisely,

$$P[Z \le z] \to \Phi(z) \text{ for every fixed } z \text{ as } n \to \infty \tag{19.11.10}$$

Normal Distribution-Related Sampling Distributions

One-Sample Case

Additional results exist when the observations come from a normal population. If $X_1, X_2, \ldots, X_n$ represent a random sample of size n from an $N(\mu,\sigma^2)$ population, then the following sample distributions are useful:

Fact 3. For every fixed n the distribution of Z given in Equation (19.11.9) has *exactly* an N(0,1) distribution.

Fact 4. The distribution of the statistic $T = \sqrt{n}(\overline{X} - \mu)/S$, where $S = \sqrt{S^2}$ is the sample standard deviation, is called a Student's t distribution with $\nu = n - 1$ degrees of freedom, in symbols, $t(n - 1)$.

This distribution is useful for making inference on μ when σ^2 is unknown; a table of the percentiles can be found in most statistics textbooks.

Fact 5. The distribution of the statistic $W = (n - 1)S^2/\sigma^2$ is called a chi-squared distribution with $\nu = n - 1$ degrees of freedom, in symbols $\chi^2(\nu)$.

Such a distribution is useful in making inference on σ^2; a table of the percentiles can also be found in most statistics books.

Two-Sample Case

In certain applications we may be interested in the comparisons of two different treatments. Suppose that independent samples from treatments T_1 and T_2 are to be observed as shown in Table 19.11.1.

TABLE 19.11.1 Summarization of Data for a Two-Sample Problem

Treatment	Observations	Distribution	Sample Size	Sample Mean	Sample Variance
T_1	$X_{11}, X_{12}, \ldots, X_{1n_1}$	$\mathcal{N}(\mu_1,\sigma_1^2)$	n_1	$\overline{X}_1$	S_1^2
T_2	$X_{21}, X_{22}, \ldots, X_{2n_2}$	$\mathcal{N}(\mu_2,\sigma_2^2)$	n_2	$\overline{X}_2$	S_2^2

The difference of the population means $(\mu_1 - \mu_2)$ and the ratio of the population variances can be estimated, respectively, by $(\overline{X}_1 - \overline{X}_2)$ and S_1^2/S_2^2. The following facts summarize the distributions of these statistics:

Fact 6. Under the assumption of normality, $(\overline{X}_1 - \overline{X}_2)$ has an $N(\mu_1 - \mu_2, (\sigma_1^2/n_1) + (\sigma_2^2/n_2))$ distribution; or equivalently, for all n_1, n_2 the statistic

$$Z = \left[\left(\overline{X}_1 - \overline{X}_2\right) - \left(\mu_1 - \mu_2\right)\right] \Big/ \left(\sigma_1^2/n_1 + \sigma_2^2/n_2\right)^{1/2} \qquad (19.11.11)$$

has an $N(0,1)$ distribution.

Fact 7. When $\sigma_1^2 = \sigma_2^2 \equiv \sigma^2$, the common population variance is estimated by

$$S_p^2 = \left(n_1 + n_2 - 2\right)^{-1}\left[\left(n_1 - 1\right)S_1^2 + \left(n_2 - 1\right)S_2^2\right] \qquad (19.11.12)$$

and $(n_1 + n_2 - 2)S_p^2/\sigma^2$ has a $\chi^2(n_1 + n_2 - 2)$ distribution.

Fact 8. When $\sigma_1^2 = \sigma_2^2$, the statistic

$$T = \left[\left(\overline{X}_1 - \overline{X}_2\right) - \left(\mu_1 - \mu_2\right)\right] \Big/ S_p\left(1/n_1 + 1/n_2\right)^{1/2} \qquad (19.11.13)$$

has a $t(n_1 + n_2 - 2)$ distribution, where $S_p = \sqrt{S_p^2}$.

Fact 9. The distribution of $F = (S_1^2/\sigma_1^2)/(S_2^2/\sigma_2^2)$ is called an F distribution with degrees of freedom $(n_1 - 1, n_2 - 1)$, in symbols, $F(n_1 - 1, n_2 - 1)$,

The percentiles of this distribution have also been tabulated and can be found in statistics books.

In the following two examples we illustrate numerically how to find probabilities and percentiles using the existing tables for the normal, Student's *t*, chi-squared, and *F* distributions.

Example 10. Suppose that in an experiment four observations are taken, and that the population is assumed to have a normal distribution with mean μ and variance σ^2. Let $\bar{X}$ and S^2 be the sample mean and sample variance as given in Equation (19.11.7).

(a) If, based on certain similar experiments conducted in the past, we know that $\sigma^2 = 1.8^2 \times 10^{-6}$ ($\sigma = 1.8 \times 10^{-3}$), then from $\Phi(-1.645) = 0.05$ and $\Phi(1.96) = 0.975$ we have

$$P\left[-1.645 \le \frac{\bar{X} - \mu}{1.8 \times 10^{-3}\ \ \sqrt{4}} \le 1.96\right] = 0.975 - 0.05 = 0.925$$

or equivalently,

$$P\left[-1.645 \times 0.9 \times 10^{-3} \le \bar{X} - \mu \le 1.96 \times 0.9 \times 10^{-3}\right] = 0.925$$

(b) The statistic $T = 2(\bar{X} - \mu)/S$ has a Student's *t* distribution with 3 degrees of freedom (in symbols, $t(3)$). From the *t* table we have

$$P\left[-3.182 \le 2\left(\bar{X} - \mu\right)\big/S \le 3.182\right] = 0.95$$

which yields

$$P\left[-3.182 \times \frac{S}{2} \le \bar{X} - \mu \le 3.182 \times \frac{S}{2}\right] = 0.95$$

or equivalently,

$$P\left[\bar{X} - 3.182 \times \frac{S}{2} \le \mu \le \bar{X} + 3.182 \times \frac{S}{2}\right] = 0.95$$

This is, in fact, the basis for obtaining the confidence interval for μ given in Equation (19.11.17) when σ^2 is unknown.

(c) The statistic $3S^2/\sigma^2$ has a chi-squared distribution with 3 degrees of freedom (in symbols, $\chi^2(3)$). Thus from the chi-squared table we have $P[0.216 \le 3S^2/\sigma^2 \le 9.348] = 0.95$, which yields

$$P\left[\frac{3S^2}{9.348} \le \sigma^2 \le \frac{3S^2}{0.216}\right] = 0.95$$

and it forms the basis for obtaining a confidence interval for σ^2 as given in Equation (19.11.18).

Example 11. Suppose that in Table 19.11.1 (with two treatments) we have $n_1 = 4$ and $n_2 = 5$, and we let $\bar{X}_1, \bar{X}_2$ and S_1^2, S_2^2 denote the corresponding sample means and sample variances, respectively.

(a) Assume that $\sigma_1^2 = \sigma_2^2$ where the common variance is unknown and is estimated by S_ρ^2 given in Equation (19.11.12). Then the statistic

$$T = \left[\left(\bar{X}_1 - \bar{X}_2\right) - \left(\mu_1 - \mu_2\right)\right]\Big/ S_p\left({}^1\!/_4 + {}^1\!/_5\right)^{1/2}$$

has a $t(7)$ distribution. Thus from the t table we have

$$P = \left[-2.998 \le \left[\left(\bar{X}_1 - \bar{X}_2\right) - \left(\mu_1 - \mu_2\right)\right] \Big/ S_p\left({}^1/_4 + {}^1/_5\right)^{1/2} \le 2.998\right] = 0.98$$

which is equivalent to saying that

$$P\left[-2.998 S_p\left({}^1/_4 + {}^1/_5\right)^{1/2} \le \mu_1 - \mu_2 \le \left(\bar{X}_1 - \bar{X}_2\right) + 2.998 S_p\left({}^1/_4 + {}^1/_5\right)^{1/2}\right] = 0.98$$

(b) The statistic $F = (S_1^2/\sigma_1^2)/(S_2^2/\sigma_2^2)$ has an $F(3,4)$ distribution. Thus from the F-table we have

$$P\left[\left(\frac{\sigma_2^2}{\sigma_1^2}\right)\left(\frac{S_1^2}{S_2^2}\right) \le 6.59\right] = 0.95$$

or equivalently,

$$P\left[\frac{\sigma_2^2}{\sigma_1^2} \le 6.59\frac{S_2^2}{S_1^2}\right] = 0.95$$

The distributions listed above (normal, Student's t, chi-squared, and F) form an integral part of the classical statistical inference theory, and they are developed under the assumption that the observations follow a normal distribution. When the distribution of the population is not normal and inference on the populations means is to be made, we conclude that (1) if the sample sizes n_1, n_2 are large, then the statistic Z in Equation (19.11.11) has an approximate $N(0,1)$ distribution and (2) in the small-sample case, the exact distribution of $\bar{X}$ (of $(\bar{X}_1 - \bar{X}_2)$)) depends on the population p.d.f. There are several analytical methods for obtaining it, and those methods can be found in statistics textbooks.

Confidence Intervals

A method for estimating the population parameters based on the sample mean(s) and sample variance(s) involves the confidence intervals for the parameters.

One-Sample Case

1. Confidence Interval for μ When σ^2 is Known. Consider the situation in which a random sample of size n is taken from an $N(\mu,\sigma^2)$ population and σ^2 is known. An interval, I_1, of the form $I_1 = (\bar{X} - d, \bar{X} + d)$ (with width $2d$) is to be constructed as a "confidence interval or μ." If we make the assertion that μ is in this interval (i.e., μ is bounded below by $\bar{X} - d$ and bounded above by $\bar{X} + d$), then sometimes this assertion is correct and sometimes it is wrong, depending on the value of $\bar{X}$ in a given experiment. If for a fixed α value we would like to have a confidence probability (called confidence coefficient) such that

$$P\left[\mu \in I_1\right] = P\left[\bar{X} - d < \mu < \bar{X} + d\right] = 1 - \alpha \tag{19.11.14}$$

then we need to choose the value of d to satisfy $d = z_{\alpha/2}\dfrac{\sigma}{\sqrt{n}}$, i.e.,

$$I_1 = \left(\bar{X} - z_{\alpha/2}\frac{\sigma}{\sqrt{n}}, \bar{X} + z_{\alpha/2}\frac{\sigma}{\sqrt{n}}\right) \tag{19.11.15}$$

where $z_{\alpha/2}$ is the $(1 - \alpha/2)$th percentile of the $N(0,1)$ distribution such that $\Phi(z_{\alpha/2}) = 1 - \alpha/2$. To see this, we note that from the sampling distribution of $\bar{X}$ (Fact 3) we have

$$P\left[\bar{X} - z_{\alpha/2}\frac{\sigma}{\sqrt{n}} < \mu < \bar{X} + z_{\alpha/2}\frac{\sigma}{\sqrt{n}}\right] = P\left[\frac{\left|\bar{X} - \mu\right|}{\sigma\ \sqrt{n}} \le z_{\alpha/2}\right] \tag{19.11.16}$$

$$= \Phi\left(z_{\alpha/2}\right) - \Phi\left(-z_{\alpha/2}\right) = 1 - \alpha$$

We further note that, even when the original population is not normal, by Theorem 2 the confidence probability is approximately (1 – α) when the sample size is reasonably large.

2. Confidence Interval for μ *When* σ^2 *is Unknown.* Assume that the observations are from an $N(\mu,\sigma^2)$ population. When σ^2 is unknown, by Fact 4 and a similar argument we see that

$$I_2 = \left(\bar{X} - t_{\alpha/2}(n-1)\frac{S}{\sqrt{n}},\ \bar{X} + t_{\alpha/2}(n-1)\frac{S}{\sqrt{n}}\right) \tag{19.11.17}$$

is a confidence interval for μ with confidence probability 1 – α, where $t_{\alpha/2}(n-1)$ is the (1 – α/2)th percentile of the $t(n-1)$ distribution.

3. Confidence Interval for σ^2*.* If, under the same assumption of normality, a confidence interval for σ^2 is needed when μ is unknown, then

$$I_3 = \left((n-1)S^2 \big/ \chi^2_{1-\alpha/2}(n-1),\ (n-1)S^2 \big/ \chi^2_{\alpha/2}(n-1)\right) \tag{19.11.18}$$

has a confidence probability 1 – α, when $\chi^2_{1-\alpha/2}\,(n-1)$ and $\chi^2_{\alpha/2}\,(n-1)$ are the (α/2)th and (1 – α/2)th percentiles, respectively, of the $\chi^2(n-1)$ distribution.

Two-Sample Case

1. Confidence Intervals for $\mu_1 - \mu_2$ *When* $\sigma_1^2 = \sigma_2^2$ *are Known.* Consider an experiment that involves the comparison of two treatments, T_1 and T_2, as indicated in Table 19.11.1. If a confidence interval for $\delta = \mu_1 - \mu_2$ is needed when σ_1^2 and σ_2^2 are unknown, then by Fact 6 and a similar argument, the confidence interval

$$I_4 = \left(\left(\bar{X}_1 - \bar{X}_2\right) - z_{\alpha/2}\sqrt{\sigma_1^2/n_1 + \sigma_2^2/n_2},\ \left(\bar{X}_1 - \bar{X}_2\right) + z_{\alpha/2}\sqrt{\sigma_1^2/n_1 + \sigma_2^2/n_2}\right) \tag{19.11.19}$$

has a confidence probability 1 – α.

2. Confidence Interval for $\mu_1 - \mu_2$ *when* σ_1^2, σ_2^2 *are Unknown but Equal.* Under the additional assumption that $\sigma_1^2 = \sigma_2^2$, but the common variance is unknown, then by Fact 8 the confidence interval

$$I_5 = \left(\left(\bar{X}_1 - \bar{X}_2\right) - d,\ \left(\bar{X}_1 - \bar{X}_2\right) + d\right) \tag{19.11.20}$$

has a confidence probability 1 – α, where

$$d = t_{\alpha/2}\left(n_1 + n_2 - 2\right) S_p \left(1/n_1 + 1/n_2\right)^{1/2} \tag{19.11.21}$$

3. Confidence Interval for σ_2^2/σ_1^2*.* A confidence interval for the ratio of the variances σ_2^2/σ_1^2 can be obtained from the F distribution (see Fact 9), and the confidence interval

$$I_6 = \left(F_{1-\alpha/2}\left(n_1 - 1, n2_1 - 1\right)\frac{S_2^2}{S_1^2}, F_{\alpha/2}\left(n_1 - 1, n2_1 - 1\right)\frac{S_2^2}{S_1^2} \right) \tag{19.11.22}$$

has a confidence probability $1 - \alpha$, where $F_{1-\alpha/2}(n_1 - 1, n_2 - 1)$ and $F_{\alpha/2}(n_1 - 1, n_2 - 1)$ are, respectively, the $(\alpha/2)$th and $(1 - \alpha/2)$th percentiles of the $F(n_1 - 1, n_2 - 1)$ distribution.

Testing Statistical Hypotheses

A statistical hypothesis concerns a statement or assertion about the true value of the parameter in a given distribution. In the two-hypothesis problems, we deal with a null hypothesis and an alternative hypothesis, denoted by H_0 and H_1, respectively. A decision is to be made, based on the data of the experiment, to either accept H_0 (hence reject H_1) or reject H_0 (hence accept H_1). In such a two-action problem, we may commit two types of errors: the type I error is to reject H_0 when it is true, and the type II error is to accept H_0 when it is false. As a standard practice, we do not reject H_0 unless there is significant evidence indicating that it may be false. (In doing so, the burden of proof that H_0 is false is on the experimenter.) Thus we usually choose a small fixed number, α (such as 0.05 or 0.01), such that the probability of committing a type I error is at most (or equal to) α. With such a given α, we can then determine the region in the data space for the rejection of H_0 (called the critical region).

One-Sample Case

Suppose that $X_1, X_2, \ldots, X_n$ represent a random sample of size n from an $N(\mu,\sigma^2)$ population, and $\overline{X}$ and S^2 are, respectively, the sample mean and sample variance.

1. Test for Mean. In testing

$$H_0 : \mu = \mu_0 \text{ vs. } H_1 : \mu = \mu_1\left(\mu_1 > \mu_0\right) \text{ or } H_1 : \mu > \mu_0$$

when σ^2 is known, we reject H_0 when $\overline{X}$ is large. To determine the cut-off point, we note (by Fact 3) that the statistic $Z_0 = (\overline{X} - \mu_0)/(\sigma/\sqrt{n})$ has an $N(0,1)$ distribution under H_0. Thus, if we decide to reject H_0 when $Z_0 > z_\alpha$, then the probability of committing a type I error is α. As a consequence, we apply the decision rule

$$d_1 : \text{reject } H_0 \text{ if and only if } \overline{X} > \mu_0 + z_\alpha \frac{\sigma}{\sqrt{n}}$$

Similarly, from the distribution of Z_0 under H_0 we can obtain the critical region for the other types of hypotheses. When σ^2 is unknown, then by Fact 4 $T_0 = \sqrt{n}(\overline{X} - \mu_0)/S$ has a $t(n-1)$ distribution under H_0. Thus the corresponding tests can be obtained by substituting $t_\alpha(n - 1)$ for z_α and S for σ. The tests for the various one-sided and two-sided hypotheses are summarized in Table 19.11.2 below. For each set of hypotheses, the critical region given on the first line is for the case when σ^2 is known, and that given on the second line is for the case when σ^2 is unknown. Furthermore, t_α and $t_{\alpha/2}$ stand for $t_\alpha(n - 1)$ and $t_{\alpha/2}(n - 1)$, respectively.

2. Test for Variance. In testing hypotheses concerning the variance σ^2 of a normal distribution, use Fact 5 to assert that, under H_0: $\sigma^2 = \sigma_0^2$, the distribution of $w_0 = (n-1)\, S^2/\sigma_0^2$ is $\chi^2(n-1)$. The corresponding tests and critical regions are summarized in the following table (χ_α^2 and $\chi_{\alpha/2}^2$ stand for $\chi_\alpha^2\,(n - 1)$ and $\chi_{\alpha/2}^2\,(n - 1)$, respectively):

Two-Sample Case

In comparing the means and variances of two normal populations, we once again refer to Table 19.11.1 for notation and assumptions.

TABLE 19.11.2 One-Sample Tests for Mean

Null Hypothesis H_0	Alternative Hypothesis H_1	Critical Region
$\mu = \mu_0$ or $\mu \le \mu_0$	$\mu = \mu_1 > \mu_0$ or $\mu > \mu_0$	$\bar{X} > \mu_0 + z_\alpha \frac{\sigma}{\sqrt{n}}$
		$\bar{X} > \mu_0 + t_\alpha \frac{S}{\sqrt{n}}$
$\mu = \mu_0$ or $\mu \ge \mu_0$	$\mu = \mu_1 < \mu_0$ or $\mu < \mu_0$	$\bar{X} < \mu_0 - z_\alpha \frac{\sigma}{\sqrt{n}}$
		$\bar{X} < \mu_0 - t_\alpha \frac{S}{\sqrt{n}}$
$\mu = \mu_0$	$\mu \ne \mu_0$	$\lvert \bar{X} - \mu_0 \rvert > z_{\alpha/2} \frac{\sigma}{\sqrt{n}}$
		$\lvert \bar{X} - \mu_0 \rvert > t_{\alpha/2} \frac{S}{\sqrt{n}}$

TABLE 19.11.3 One-Sample Tests for Variance

Null Hypothesis H_0	Alternative Hypothesis H_1	Critical Region
$\sigma^2 = \sigma_0^2$ or $\sigma^2 \le \sigma_0^2$	$\sigma^2 = \sigma_1^2 > \sigma_0^2$ or $\sigma^2 > \sigma_0^2$	$\left(S^2/\sigma_0^2\right) > \frac{1}{n-1}\chi_\alpha^2$
$\sigma^2 = \sigma_0^2$ or $\sigma^2 \ge \sigma_0^2$	$\sigma^2 = \sigma_1^2 < \sigma_0^2$ or $\sigma^2 < \sigma_0^2$	$\left(S^2/\sigma_0^2\right) < \frac{1}{n-1}\chi_{1-\alpha}^2$
$\sigma^2 = \sigma_0^2$	$\sigma^2 \ne \sigma_0^2$	$\left(S^2/\sigma_0^2\right) > \frac{1}{n-1}\chi_{\alpha/2}^2$
		or $\left(S^2/\sigma_0^2\right) < \frac{1}{n-1}\chi_{1-\alpha/2}^2$

1. Test for Difference of Two Means. Let $\delta = \mu_1 - \mu_2$ be the difference of the two population means. In testing H_0: $\delta = \delta_0$ vs. a one-sided or two-sided alternative hypothesis, we note that, for

$$\tau = \left(\sigma_1^2/n_1 + \sigma_2^2/n_2\right)^{1/2} \tag{19.11.23}$$

and

$$\nu = S_p\left(1/n_1 + 1/n_2\right)^{1/2} \tag{19.11.24}$$

$Z_0 = [\,(\bar{X}_1 - \bar{X}_2) - \delta_0]/\tau$ has an $N(0,1)$ distribution under H_0 and $T_0 = [\,(\bar{X}_1 - \bar{X}_2) - \delta_0]/\nu$ has a $t(n_1 + n_2 - 2)$ distribution under H_0 when $\sigma_1^2 = \sigma_2^2$. Using these results, the corresponding critical regions for one-sided and two-sided tests can be obtained, and they are listed below. Note that, as in the one-sample case, the critical region given on the first line for each set of hypotheses is for the case of known variances, and that given on the second line is for the case in which the variances are equal but unknown. Further, t_α and $t_{\alpha/2}$ stand for $t_\alpha(n_1 + n_2 - 2)$ and $t_{\alpha/2}(n_1 + n_2 - 2)$, respectively.

A Numerical Example

In the following we provide a numerical example for illustrating the construction of confidence intervals and hypothesis-testing procedures. The example is given along the line of applications in Wadsworth (1990, p. 4.21) with artificial data.

TABLE 19.11.4 Two-Sample Tests for Difference of Two Means

Null Hypothesis H_0	Alternative Hypothesis H_1	Critical Region
$\delta = \delta$ or $\delta \le \delta_0$	$\delta = \delta_1 > \delta_0$ or $\delta > \delta_0$	$\left(\bar{X}_1 - \bar{X}_2\right) > \delta_0 + z_\alpha \tau$
		$\left(\bar{X}_1 - \bar{X}_2\right) > \delta_0 + t_\alpha \nu$
$\delta = \delta_0$ or $\delta \ge \delta_0$	$\delta = \delta_1 < \delta_0$ or $\delta < \delta_0$	$\left(\bar{X}_1 - \bar{X}_2\right) < \delta_0 - z_\alpha \tau$
		$\left(\bar{X}_1 - \bar{X}_2\right) < \delta_0 - t_\alpha \nu$
$\delta = \delta_0$	$\delta \ne \delta_0$	$\left\lvert\left(\bar{X}_1 - \bar{X}_2\right) - \delta_0\right\rvert > z_{\alpha/2}\tau$
		$\left\lvert\left(\bar{X}_1 - \bar{X}_2\right) - \delta_0\right\rvert > t_{\alpha/2}\nu$

Suppose that two processes (T_1 and T_2) manufacturing steel pins are in operation, and that a random sample of 4 pins (or 5 pins) was taken from the process T_1 (the process T_2) with the following results (in units of inches):

$$T_1 : 0.7608, 0.7596, 0.7622, 0.7638$$

$$T_2 : 0.7546, 0.7561, 0.7526, 0.7572, 0.7565$$

Simple calculation shows that the observed values of sample means sample variances, and sample standard deviations are:

$$\bar{X}_1 = 0.7616, \quad S_1^2 = 3.280 \times 10^{-6}, \quad S_1 = 1.811 \times 10^{-3}$$

$$\bar{X}_2 = 0.7554, \quad S_2^2 = 3.355 \times 10^{-6}, \quad S_2 = 1.832 \times 10^{-3}$$

One-Sample Case

Let us first consider confidence intervals for the parameters of the first process, T_1, only.

1. Assume that, based on previous knowledge of processes of this type, the variance is known to be $\sigma_1^2 = 1.80^2 \times 10^{-6}$ ($\sigma_1 = 0.0018$). Then from the normal table (see, e.g., Ross (1987, p. 482) we have $z_{0.025} = 1.96$. Thus a 95% confidence interval for μ_1 is

$$\left(0.7616 - 1.96 \times 0.0018/\sqrt{4}, 0.7616 + 1.96 \times 0.0018/\sqrt{4}\right)$$

   or (0.7598, 0.7634) (after rounding off to the 4th decimal place).

2. If σ_1^2 is unknown and a 95% confidence interval for μ_1 is needed then, for $t_{0.023}(3) = 3.182$ (see, e.g., Ross, 1987, p. 484) the confidence interval is

$$\left(0.7616 - 3.182 \times 0.001811/\sqrt{4}, 0.7616 + 3.182 \times 0.001811/\sqrt{4}\right)$$

   or (0.7587, 0.7645)

3. From the chi-squared table with 4 – 1 = 3 degrees of freedom, we have (see, e.g., Ross, 1987, p. 483) $\chi^2_{0.975} = 0.216$, $\chi^2_{0.025} = 9.348$. Thus a 95% confidence interval for σ_1^2 is ($3 \times 3.280 \times 10^{-6}/9.348$, $3 \times 3.280 \times 10^{-6}/0.216$), or ($1.0526 \times 10^{-6}$, $45,5556 \times 10^{-6}$).

4. In testing the hypotheses

$$H_0 : \mu_1 = 0.76 \text{ vs. } H_1 : \mu_1 > 0.76$$

with a = 0.01 when σ_1^2 is unknown, the critical region is $\bar{x}_1 > 0.76 + 4.541 \times 0.001811/\sqrt{4} = 0.7641$. Since the observed value $\bar{x}_1$ is 0.7616, H_0 is accepted. That is, we assert that there is no significant evidence to call for the rejection of H_0.

Two-Sample Case

If we assume that the two populations have a common unknown variance, we can use the Student's *t* distribution (with degree of freedom $\nu = 4 + 5 - 2 = 7$) to obtain confidence intervals and to test hypotheses for $\mu_1 - \mu_2$. We first note that the data given above yield

$$S_p^2 = \frac{1}{7}(3 \times 3.280 + 4 \times 3.355) \times 10^{-6}$$

$$= 3.3229 \times 10^{-6}$$

$$S_p = 1.8229 \times 10^{-3} \qquad \nu = S_p\sqrt{1/4 + 1/5} = 1.2228 \times 10^{-3}$$

and $\bar{X}_1 - \bar{X}_2 = 0.0062$.

1. A 98% confidence interval for $\mu_1 - \mu_2$ is $(0.0062 - 2.998\nu, 0.0062 + 2.998\nu)$ or (0.0025, 0.0099).
2. In testing the hypotheses H_0: $\mu_1 = \mu_2$ (i.e., $\mu_1 - \mu_2 = 0$) vs. H_1: $\mu_1 > \mu_2$ with $\alpha = 0.05$, the critical region is $(\bar{X}_1 - \bar{X}_2) > 1.895\nu = 2.3172 \times 10^{-3}$. Thus H_0 is rejected; i.e., we conclude that there is significant evidence to indicate that $\mu_1 > \mu_2$ may be true.
3. In testing the hypotheses H_0: $\mu_1 = \mu_2$ vs. $\mu_1 \neq \mu_2$ with $\alpha = 0.02$, the critical region is $|\bar{X}_1 - \bar{X}_2| > 2.998\nu = 3.6660 \times 10^{-3}$. Thus H_0 is rejected. We note that the conclusion here is consistent with the result that, with confidence probability $1 - \alpha = 0.98$, the confidence interval for $(\mu_1 - \mu_2)$ does not contain the origin.

Concluding Remarks

The history of probability and statistics goes back to the days of the celebrated mathematicians K. F. Gauss and P. S. Laplace. (The normal distribution, in fact, is also called the Gaussian distribution.) The theory and methods of classical statistical analysis began its developments in the late 1800s and early 1900s when F. Galton and R.A. Fisher applied statistics to their research in genetics, when Karl Pearson developed the chi-square goodness-of-fit method for stochastic modeling, and when E.S. Pearson and J. Neyman developed the theory of hypotheses testing. Today statistical methods have been found useful in analyzing experimental data in biological science and medicine, engineering, social sciences, and many other fields. A non-technical review on some of the applications is Hacking (1984).

Applications of statistics in engineering include many topics. In addition to those treated in this section, other important ones include sampling inspection and quality (process) control, reliability, regression analysis and prediction, design of engineering experiments, and analysis of variance. Due to space limitations, these topics are not treated here. The reader is referred to textbooks in this area for further information. There are many well-written books that cover most of these topics, the following short list consists of a small sample of them.

19.12 Numerical Methods

William F. Ames

Introduction

Since many mathematical models of physical phenomena are not solvable by available mathematical methods one must often resort to approximate or numerical methods. These procedures do not yield exact results in the mathematical sense. This inexact nature of numerical results means we must pay attention to the errors. The two errors that concern us here are *round-off errors* and *truncation errors.*

Round-off errors arise as a consequence of using a number specified by m correct digits to approximate a number which requires more than m digits for its exact specification. For example, using 3.14159 to approximate the irrational number π. Such errors may be especially serious in matrix inversion or in any area where a very large number of numerical operations are required. Some attempts at handling these errors are called *enclosure methods.* (Adams and Kulisch, 1993).

Truncation errors arise from the substitution of a finite number of steps for an infinite sequence of steps (usually an iteration) which would yield the exact result. For example, the iteration $y_n(x) = 1 + \int_0^x xty_{n-1}(t)dt$, $y(0) = 1$ is only carried out for a *few steps*, but it converges in *infinitely* many steps.

The study of some errors in a computation is related to the theory of probability. In what follows, a relation for the error will be given in certain instances.

Linear Algebra Equations

A problem often met is the determination of the solution vector $u = (u_1, u_2, \ldots, u_n)^T$ for the set of linear equations $Au = v$ where A is the $n \times n$ square matrix with coefficients, a_{ij} $(i, j = 1, \ldots, n)$, $v = (v_1, \ldots, v_n)^T$ and i denotes the row index and j the column index.

There are many numerical methods for finding the solution, u, of $Au = v$. The direct inversion of A is usually too expensive and is not often carried out unless it is needed elsewhere. We shall only list a few methods. One can check the literature for the many methods and computer software available. Some of the software is listed in the References section at the end of this chapter. The methods are usually subdivided into *direct* (once through) or *iterative* (repeated) procedures.

In what follows, it will often be convenient to partition the matrix A into the form $A = U + D + L$, where U, D, and L are matrices having the same elements as A, respectively, above the main diagonal, on the main diagonal, and below the main diagonal, and zeros elsewhere. Thus,

$$U = \begin{bmatrix} 0 & a_{12} & & \cdots & a_{1n} \\ 0 & 0 & a_{23} & \cdots & a_{2n} \\ \vdots & \cdots & & \cdots & \\ 0 & 0 & \cdots & \cdots & 0 \end{bmatrix}$$

We also assume the u_js are not all zero and det $A \neq 0$ so the solution is unique.

Direct Methods

Gauss Reduction. This classical method has spawned many variations. It consists of dividing the first equation by a_{11} (if $a_{11} = 0$, reorder the equations to find an $a_{11} \neq 0$) and using the result to eliminate the terms in u_1 from each of the succeeding equations. Next, the modified second equation is divided by a'_{22} (if $a'_{22} = 0$, a reordering of the modified equations may be necessary) and the resulting equation is used to eliminate all terms in u_2 in the succeeding modified equations. This elimination is done n times resulting in a triangular system:

$$\begin{aligned}
u_1 + a'_{12}u_2 + \cdots + a'_{1n}u_n &= v'_1 \\
0 + u_2 + \cdots + a'_{2n}u_n &= v'_2 \\
&\cdots \\
0 + \cdots + u_{n-1} + a'_{n-1,n}u_n &= v'_{n-1} \\
u_n &= v'_n
\end{aligned}$$

where a'_{ij} and v'_j represent the specific numerical values obtained by this process. The solution is obtained by working backward from the last equation. Various modifications, such as the Gauss-Jordan reduction, the Gauss-Doolittle reduction, and the Crout reduction, are described in the classical reference authored by Bodewig (1956). Direct methods prove very useful for sparse matrices and banded matrices that often arise in numerical calculation for differential equations. Many of these are available in computer packages such as IMSL, Maple, Matlab, and Mathematica.

The Tridiagonal Algorithm. When the linear equations are tridiagonal, the system

$$\begin{aligned}
b_1u_1 + c_1u_2 &= d_1 \\
a_iu_{i-1} + b_iu_i + c_iu_{i+1} &= d_i \\
a_nu_{n-1} + b_nu_n \qquad &= d_n, \quad i = 2, 3, \ldots, n-1
\end{aligned}$$

can be solved explicitly for the unknown, thereby eliminating any matrix operations.

The Gaussian elimination process transforms the system into a simpler one of *upper bidiagonal* form. We designate the coefficients of this new system by a'_i, b'_i c'_i and d'_i, and we note that

$$\begin{aligned}
a'_i &= 0, \quad i = 2, 3, \ldots, n \\
b'_i &= 1, \quad i = 1, 2, \ldots, n
\end{aligned}$$

The coefficients c'_i and d'_i are calculated successively from the relations

$$\begin{aligned}
c'_1 &= \frac{c_1}{b_1} \qquad d'_1 = \frac{d_1}{b_1} \\
c'_{i+1} &= \frac{c_{i+1}}{b_{i+1} - a_{i+1}c'_i} \\
d'_{i+1} &= \frac{d_{i+1} - a_{i+1}d'_i}{b_{i+1} - a_{i+1}c'_i}, \quad i = 1, 2, \ldots, n-1
\end{aligned}$$

and, of course, $c_n = 0$.

Having completed the elimination we examine the new system and see that the nth equation is now

$$u_n = d'_n$$

Substituting this value into the $(n-1)$st equation,

$$u_{n-1} + c'_{n-1}u_n = d'_{n-1}$$

we have

$$u_{n-1} = d'_{n-1} - c'_{n-1}u_n$$

Thus, starting with u_n, we have successively the solution for u_i as

$$u_i = d'_i - c'_i u_{i+1}, \quad i = n-1,\ n-2,\ \ldots,\ 1$$

Algorithm for Pentadiagonal Matrix. The equations to be solved are

$$a_i u_{i-2} + b_i u_{i-1} + c_i u_i + d_i u_{i+1} + e_i u_{i+2} = f_i$$

for $1 \le i \le R$ with $a_1 = b_1 = a_2 = e_{R-1} = d_R = e_R = 0$.

The algorithm is as follows. First, compute

$$\delta_1 = d_1/c_1$$
$$\lambda_1 = e_1/c_1$$
$$\gamma_1 = f_1/c_1$$

and

$$\mu_2 = c_2 - b_2\delta_1$$
$$\delta_2 = (d_2 - b_2\lambda_1)/\mu_2$$
$$\lambda_2 = e_2/\mu_2$$
$$\gamma_2 = (f - b_2\gamma_1)/\mu_2$$

Then, for $3 \le i \le R-2$, compute

$$\beta_i = b_i - a_i\delta_{i-2}$$
$$\mu_i = c_i - \beta_i\delta_{i-1} - a_i\lambda_{i-2}$$
$$\delta_i = (d_i - \beta_i\lambda_{i-1})/\mu_i$$
$$\lambda_i = e_i/\mu_i$$
$$\gamma_i = (f_i - \beta_i\gamma_{i-1} - a_i\gamma_{i-2})/\mu_i$$

Next, compute

$$\beta_{R-1} = b_{R-1} - a_{R-1}\delta_{R-3}$$

$$\mu_{R-1} = c_{R-1} - \beta_{R-1}\delta_{R-2} - a_{R-1}\lambda_{R-3}$$

$$\delta_{R-1} = \left(d_{R-1} - \beta_{R-1}\lambda_{R-2}\right)/\mu_{R-1}$$

$$\gamma_{R-1} = \left(f_{R-1} - \beta_{R-1}\gamma_{R-2} - a_{R-1}\gamma_{R-3}\right)/\mu_{R-1}$$

and

$$\beta_R = b_R - a_R\delta_{R-2}$$

$$\mu_R = c_R - \beta_R\delta_{R-1} - a_R\lambda_{R-2}$$

$$\gamma_R = \left(f_R - \beta_R\gamma_{R-1} - a_R\gamma_{R-2}\right)/\mu_R$$

The β_i and μ_i are used only to compute δ_i, λ_i, and γ_i, and need not be stored after they are computed. The δ_i, λ_i, and γ_i, must be stored, as they are used in the back solution. This is

$$u_R = \gamma_R$$

$$u_{R-1} = \gamma_{R-1} - \delta_{R-1}u_R$$

and

$$u_i = \gamma_i - \delta_i u_{i+1} - \lambda_i u_{i+2}$$

for $R - 2 \geq i \geq 1$.

General Band Algorithm. The equations are of the form

$$A_j^{(M)}X_{j-M} + A_j^{(M-1)}X_{j-M+1} + \cdots + A_j^{(2)}X_{j-2} + A_j^{(1)}X_{j-1} + B_jX_j$$

$$+ C_j^{(1)}X_{j+1} + C_j^{(2)}X_{j+2} + \cdots + C_j^{(M-1)}X_{j+M-1} + C_j^{(M)}X_{j+M} = D_j$$

for $1 \leq j \leq N$, $N \geq M$. The algorithm used is as follows:

$$\alpha_j^{(k)} = A_j^{(k)} = 0, \quad \text{for } k \geq j$$

$$C_j^{(k)} = 0, \quad \text{for } k \geq N + 1 - j$$

The forward solution ($j = 1, \ldots, N$) is

$$\alpha_j^{(k)} = A_j^{(k)} - \sum_{p=k+1}^{p=M} \alpha_j^{(p)} W_{j-p}^{(p-k)}, \quad k = M, \ldots, 1$$

$$\beta_j = B_j - \sum_{p=1}^{M} \alpha_j^{(p)} W_{j-p}^{(p)}$$

$$W_j^{(k)} = \left(C_j^{(k)} - \sum_{p=k+1}^{p=M} \alpha_j^{(p-k)} W_{j-(p-k)}^{(p)} \right) \Bigg/ \beta_j, \quad k = 1, \ldots, M$$

$$\gamma_j = \left(D_j - \sum_{p=1}^{M} \alpha_j^{(p)} \gamma_{j-p} \right) \Big/ \beta_j$$

The back solution ($j = N, \ldots, 1$) is

$$X_j = \gamma_j - \sum_{p=1}^{M} W_j^{(p)} X_{j+p}$$

Cholesky Decomposition. When the matrix A is a symmetric and positive definite, as it is for many discretizations of self-adjoint positive definite boundary value problems, one can improve considerably on the band procedures by using the Cholesky decomposition. For the system $Au = v$, the Matrix A can be written in the form

$$A = (I + L)D(I + U)$$

where L is lower triangular, U is upper triangular, and D is diagonal. If $A = A'$ (A' represents the transpose of A), then

$$A = A' = (I + U)' D(I + L)'$$

Hence, because of the uniqueness of the decomposition.

$$I + L = (I + U)' = I + U'$$

and therefore,

$$A = (I + U)' D(I + U)$$

that is,

$$A = B'B, \text{ where } B = \sqrt{D}(I + U)$$

The system $Au = v$ is then solved by solving the two triangular system

$$B'w = v$$

followed by

$$Bu = w$$

To carry out the decomposition $A = B'B$, all elements of the first row of A, and of the derived system, are divided by the square root of the (positive) leading coefficient. This yields smaller rounding errors than the banded methods because the relative error of $\sqrt{a}$ is only half as large as that of a itself. Also, taking the square root brings numbers nearer to each other (i.e., the new coefficients do not differ as widely as the original ones do). The actual computation of $B = (b_{ij})$, $j > i$, is given in the following:

$$
\begin{aligned}
&b_{11} = \left(a_{11}\right)^{1/2}, && b_{1j} = a_{ij}/b_{11}, \quad j \ge 2\\
&b_{22} = \left(a_{22} - b_{12}^2\right)^{1/2}, && b_{2j} = \left(a_{2j} - b_{12}b_{1j}\right)/b_{22}\\
&b_{33} = \left(a_{33} - b_{13}^2 - b_{23}^2\right)^{1/2}, && b_{3j} = \left(a_{3j} - b_{13}b_{1j} - b_{23}b_{2j}\right)/b_{33}\\
&\quad\vdots\\
&b_{ii} = \left(a_{ii} - \sum_{k=1}^{i-1} b_{ki}^2\right)^{1/2}, && b_{ij} = \left(a_{ij} - \sum_{k=1}^{i-1} b_{ki}b_{kj}\right)\Bigg/b_{ii}, \qquad i \ge 2,\ j \ge 2
\end{aligned}
$$

Iterative Methods

Iterative methods consist of repeated application of an often simple algorithm. They yield the exact answer only as the limit of a sequence. They can be programmed to take care of zeros in A and are self-correcting. Their structure permits the use of convergence accelerators, such as overrelaxation, Aitkins acceleration, or Chebyshev acceleration.

Let $a_{ii} > 0$ for all i and $\det A \neq 0$. With $A = U + D + L$ as previously described, several iteration methods are described for $(U + D + L)u = v$.

Jacobi Method (Iteration by total steps). Since $u = -D^{-1}[U + L]u + D^{-1}v$, the iteration $u^{(k)}$ is $u^{(k)} = -D^{-1}[U + L]u^{(k-1)} + D^{-1}v$. This procedure has a slow convergent rate designated by R, $0 < R \ll 1$.

Gauss-Seidel Method (Iteration by single steps). $u^{(k)} = -(L + D)^{-1}Uu^{(k-1)} + (L + D)^{-1}v$. Convergence rate is $2R$, twice as fast as that of the Jacobi method.

Gauss-Seidel with Successive Overrelaxation (SOR). Let $\bar{u}_i^{(k)}$ be the ith components of the Gauss-Seidel iteration. The SOR technique is defined by

$$u_i^{(k)} = (1-\omega)u_i^{(k-1)} + \omega\bar{u}_i^{(k)}$$

where $1 < \omega < 2$ is the overrelaxation parameter. The full iteration is $u^{(k)} = (D + \omega L)^{-1}\{[(1 - \omega)D - \omega U]u^{(k-1)} + \omega v\}$. Optimal values of ω can be computed and depend upon the properties of A (Ames, 1993). With optimal values of ω, the convergence rate of this method is $2R\sqrt{2}$ which is much larger than that for Gauss-Seidel (R is usually much less than one).

For other acceleration techniques, see the literature (Ames, 1993).

Nonlinear Equations in One Variable

Special Methods for Polynomials

The polynomial $P(x) = a_0x^n + a_1x^{n-1} + \cdots + a_{n-1}x + a_n = 0$, with real coefficients a_j, $j = 0, \ldots, n$, has exactly n roots which may be real or complex.

If all the coefficients of $P(x)$ are integers, then any rational roots, say r/s (r and s are integers with no common factors), of $P(x) = 0$ must be such that r is an integral divisor of a_n and s is an integral division of a_0. Any polynomial with rational coefficients may be converted into one with integral coefficients by multiplying the polynomial by the lowest common multiple of the denominators of the coefficients.

Example. $x^4 - 5x^2/3 + x/5 + 3 = 0$. The lowest common multiple of the denominators is 15. Multiplying by 15, which does not change the roots, gives $15x^4 - 25x^2 + 3x + 45 = 0$. The only possible rational roots r/s are such that r may have the value ±45, ±15, ±5, ±3, and ±1, while s may have the values ±15, ±5, ±3, and ±1. All possible rational roots, with no common factors, are formed using all possible quotients.

If $a_0 > 0$, the first negative coefficient is preceded by k coefficients which are positive or zero, and G is the largest of the absolute values of the negative coefficients, then each real root is less than $1 + \sqrt[k]{G/a_0}$ (upper bound on the real roots). For a lower bound to the real roots, apply the criterion to $P(-x) = 0$.

Example. $P(x) = x^5 + 3x^4 - 2x^3 - 12x + 2 = 0$. Here $a_0 = 1$, $G = 12$, and $k = 2$. Thus, the upper bound for the real roots is $1 + \sqrt[2]{12} \approx 4.464$. For the lower bound, $P(-x) = -x^5 + 3x^4 + 2x^3 + 12x + 2 = 0$, which is equivalent to $x^5 - 3x^4 - 2x^3 - 12x - 2 = 0$. Here $k = 1$, $G = 12$, and $a_0 = 1$. A lower bound is $-(1 + 12) = 13$. Hence all real roots lie in $-13 < x < 1 + \sqrt[2]{12}$.

A useful *Descartes rule of signs* for the number of positive or negative real roots is available by observation for polynomials with real coefficients. The number of positive real roots is either equal to the number of sign changes, n, or is less than n by a positive *even* integer. The number of negative real roots is either equal to the number of sign changes, n, of $P(-x)$, or is less than n by a positive even integer.

Example. $P(x) = x^5 - 3x^3 - 2x^2 + x - 1 = 0$. There are three sign changes, so $P(x)$ has either three or one positive roots. Since $P(-x) = -x^5 + 3x^3 - 2x^2 - 1 = 0$, there are either two or zero negative roots.

The Graeffe Root-Squaring Technique

This is an iterative method for finding the roots of the algebraic equation

$$f(x) = a_0x^p + a_1x^{p-1} + \cdots + a_{p-1}x + a_p = 0$$

If the roots are $r_1, r_2, r_3, \ldots$, then one can write

$$S_p = r_1^p\left(1 + \frac{r_2^p}{r_1^p} + \frac{r_3^p}{r_1^p} + \cdots\right)$$

and if one root is larger than all the others, say r_1, then for large enough p all terms (other than 1) would become negligible. Thus,

$$S_p \approx r_1^p$$

or

$$\lim_{p\to\infty} S_p^{1/p} = r_1$$

The Graeffe procedure provides an efficient way for computing S_p via a sequence of equations such that the roots of each equation are the squares of the roots of the preceding equations in the sequence. This serves the purpose of ultimately obtaining an equation whose roots are so widely separated in magnitude that they may be read approximately from the equation by inspection. The basic procedure is illustrated for a polynomial of degree 4:

$$f(x) = a_0x^4 + a_1x^3 + a_2x^2 + a_3x + a_4 = 0$$

Rewrite this as

$$a_0x^4 + a_2x^2 + a_4 = -a_1x^3 - a_3x$$

and square both sides so that upon grouping

$$a_0^2x^8 + \left(2a_0a_2 - a_1^2\right)x^6 + \left(2a_0a_4 - 2a_1a_3 + a_2^2\right)x^4 + \left(2a_2a_4 - a_3^2\right)x^2 + a_4^2 = 0$$

Because this involves only even powers of x, we may set $y = x^2$ and rewrite it as

$$a_0^2 y^4 + \left(2a_0 a_2 - a_1^2\right) y^3 + \left(2a_0 a_4 - 2a_1 a_3 + a_2^2\right) y^2 + \left(2a_2 a_4 - a_3^2\right) y + a_4^2 = 0$$

whose roots are the squares of the original equation. If we repeat this process again, the new equation has roots which are the fourth power, and so on. After p such operations, the roots are 2^p (original roots). If at any stage we write the coefficients of the unknown in sequence

$$a_0^{(p)} \quad a_1^{(p)} \quad a_2^{(p)} \quad a_3^{(p)} \quad a_4^{(p)}$$

then, to get the new sequence $a_i^{(p+1)}$, write $a_i^{(p+1)} = 2a_0^{(p)}$ (times the symmetric coefficient) with respect to $a_i^{(p)} - 2a_1^{(p)}$ (times the symmetric coefficient) $- \cdots (-1)^{\mathrm{i}}\, a_i^{(p)2}$. Now if the roots are r_1, r_2, r_3, and r_4, then $\mathrm{a}_1/\mathrm{a}_0 = -\Sigma_{i-1}^4 r_i$, $a_i^{(1)}/a_0^{(1)} = -\Sigma r_i^2, \ldots, a_i^{(p)}/a_0^{(p)} = -\Sigma r_i^{2p}$. If the roots are all distinct and r_1 is the largest in magnitude, then eventually

$$r_1^{2p} \approx -\frac{a_1^{(p)}}{a_0^{(p)}}$$

And if r_2 is the next largest in magnitude, then

$$r_2^{2p} \approx -\frac{a_2^{(p)}}{a_1^{(p)}}$$

And, in general $a_n^{(p)}/a_{n-1}^{(p)} \approx -r_n^{2p}$. This procedure is easily generalized to polynomials of arbitrary degree and specialized to the case of multiple and complex roots.

Other methods include Bernoulli iteration, Bairstow iteration, and Lin iteration. These may be found in the cited literature. In addition, the methods given below may be used for the numerical solution of polynomials.

General Methods for Nonlinear Equations in One Variable

Successive Substitutions

Let $f(x) = 0$ be the nonlinear equation to be solved. If this is rewritten as $x = F(x)$, then an iterative scheme can be set up in the form $x_{k+1} = F(x_k)$. To start the iteration, an initial guess must be obtained graphically or otherwise. The convergence or divergence of the procedure depends upon the method of writing $x = F(x)$, of which there will usually be several forms. A general rule to ensure convergence cannot be given. However, if a is a root of $f(x) = 0$, a necessary condition for convergence is that $|F'(x)| < 1$ in that interval about a in which the iteration proceeds (this means the iteration cannot converge unless $|F'(x)| < 1$, but it does not ensure convergence). This process is called *first order* because the error in x_{k+1} is proportional to the first power of the error in x_k.

Example. $f(x) = x^3 - x - 1 = 0$. A rough plot shows a real root of approximately 1.3. The equation can be written in the form $x = F(x)$ in several ways, such as $x = x^3 - 1$, $x = 1/(x^2 - 1)$, and $x = (1 + x)^{1/3}$. In the first case, $F'(x) = 3x^2 = 5.07$ at $x = 1.3$; in the second, $F'(1.3) = 5.46$; only in the third case is $F'(1.3) < 1$. Hence, only the third iterative process has a chance to converge. This is illustrated in the iteration table below.

Step k	$x = \dfrac{1}{x^2 - 1}$	$x = x^3 - 1$	$x = (1 + x)^{1/3}$
0	1.3	1.3	1.3
1	1.4493	1.197	1.32
2	0.9087	0.7150	1.3238
3	–5.737	–0.6345	1.3247
4	⋯	⋯	1.3247

Numerical Solution of Simultaneous Nonlinear Equations

The techniques illustrated here will be demonstrated for two simultaneous equations — $f(x, y) = 0$ and $g(x, y) = 0$. They immediately generalize to more than two simultaneous equations.

The Method of Successive Substitutions

The two simultaneous equations can be written in various ways in equivalent forms

$$x = F(x, y)$$

$$y = G(x, y)$$

and the method of successive substitutions can be based on

$$x_{k+1} = F(x_k, y_k)$$

$$y_{k+1} = G(x_k, y_k)$$

Again, the procedure is of the first order and a necessary condition for convergence is

$$\left|\frac{\partial F}{\partial x}\right| + \left|\frac{\partial F}{\partial y}\right| < 1 \qquad \left|\frac{\partial G}{\partial x}\right| + \left|\frac{\partial G}{\partial y}\right| < 1$$

in the iteration neighborhood of the true solution.

The Newton-Raphson Procedure

Using the two simultaneous equation, start from an approximate, say (x_0, y_0), obtained graphically or from a two-way table. Then, solve successively the linear equations

$$\Delta x_k \frac{\partial f}{\partial x}(x_k, y_k) + \Delta y_k \frac{\partial f}{\partial y}(x_k, y_k) = -f(x_k, y_k)$$

$$\Delta x_k \frac{\partial g}{\partial x}(x_k, y_k) + \Delta y_k \frac{\partial g}{\partial y}(x_k, y_k) = -g(x_k, y_k)$$

for Δx_k and Δy_k. Then, the $k + 1$ approximation is given from $x_{k+1} = x_k + \Delta x_k, y_{k+1} = y_k + \Delta y_k$. A modification consists in solving the equations with (x_k, y_k) replaced by (x_0, y_0) (or another suitable pair later on in the iteration) in the derivatives. This means the derivatives (and therefore the coefficients of Δx_k, Δy_k) are independent of k. Hence, the results become

$$\Delta x_k = \frac{-f(x_k,y_k)(\partial g/\partial y)(x_0,y_0) + g(x_k,y_k)(\partial f/\partial y)(x_0,y_0)}{(\partial f/\partial x)(x_0,y_0)(\partial g/\partial y)(x_0,y_0) - (\partial f/\partial y)(x_0,y_0)(\partial g/\partial x)(x_0,y_0)}$$

$$\Delta y_k = \frac{-g(x_k,y_k)(\partial f/\partial x)(x_0,y_0) + f(x_k,y_k)(\partial g/\partial x)(x_0,y_0)}{(\partial f/\partial x)(x_0,y_0)(\partial g/\partial y)(x_0,y_0) - (\partial f/\partial y)(x_0,y_0)(\partial g/\partial x)(x_0,y_0)}$$

and $x_{k+1} = \Delta x_k + x_k$, $y_{k+1} = \Delta y_k + y_k$. Such an alteration of the basic technique reduces the rapidity of convergence.

Example

$$f(x,y) = 4x^2 + 6x - 4xy + 2y^2 - 3$$

$$g(x,y) = 2x^2 - 4xy + y^2$$

By plotting, one of the approximate roots is found to be $x_0 = 0.4$, $y_0 = 0.3$. At this point, there results $\partial f/\partial x = 8$, $\partial f/\partial y = -0.4$, $\partial g/\partial x = 0.4$, and $\partial g/\partial y = -1$. Hence,

$$x_{k+1} = x_k + \Delta x_k = x_k + \frac{-f(x_k,y_k) - 0.4g(x_k,y_k)}{8(-1)-(-0.4)(0.4)}$$

$$= x_k - 0.127\,55 f(x_k,y_k) - 0.051\,02 g(x_k,y_k)$$

and

$$y_{k+1} = y_k - 0.051\,02 f(x_k,y_k) + 1.020\,41 g(x_k,y_k)$$

The first few iteration steps are shown in the following table.

Step k	x_k	y_k	$f(x_k, y_k)$	$g(x_k, y_k)$
0	0.4	0.3	–0.26	0.07
1	0.43673	0.24184	0.078	0.0175
2	0.42672	0.25573	–0.0170	–0.007
3	0.42925	0.24943	0.0077	0.0010

Methods of Perturbation

Let $f(x) = 0$ be the equation. In general, the iterative relation is

$$x_{k+1} = x_k - \frac{f(x_k)}{\alpha_k}$$

where the iteration begins with x_0 as an initial approximation and α_k is some functional.

The Newton-Raphson Procedure. This variant chooses $\alpha_k = f'(x_k)$ where $f' = df/dx$ and geometrically consists of replacing the graph of $f(x)$ by the tangent line at $x = x_k$ in each successive step. If $f'(x)$ and $f''(x)$ have the same sign throughout an interval $a \le x \le b$ containing the solution, with $f(a)$ and $f(b)$ of opposite signs, then the process converges starting from any x_0 in the interval $a \le x \le b$. The process is second order.

Example

$$f(x) = x - 1 + \frac{(0.5)^x - 0.5}{0.3}$$

$$f'(x) = 1 - 2.3105[0.5]^x$$

An approximate root (obtained graphically) is 2.

Step k	x_k	$f(x_k)$	$f'(x_k)$
0	2	0.1667	0.4224
1	1.605	–0.002	0.2655
2	1.6125	–0.0005	⋯

The Method of False Position. This variant is commenced by finding x_0 and x_1 such that $f(x_0)$ and $f(x_1)$ are of opposite signs. Then, α_1 = slope of secant line joining $[x_0, f(x_0)]$ and $[x_1, f(x_1)]$ so that

$$x_2 = x_1 - \frac{x_1 - x_0}{f(x_1) - f(x_0)} f(x_1)$$

In each following step, α_k is the slope of the line joining $[x_k, f(x_k)]$ to the most recently determined point where $f(x_j)$ has the opposite sign from that of $f(x_k)$. This method is of first order.

The Method of Wegstein

This is a variant of the method of successive substitutions which forces or accelerates convergence. The iterative procedure $x_{k+1} = F(x_k)$ is revised by setting $\hat{x}_{k+1} = F(x_k)$ and then taking $x_{k+1} = qx_k + (1 - q)\,\hat{x}_{k+1}$. Wegstein found that suitably chosen qs are related to the basic process as follows:

Behavior of Successive Substitution Process	Range of Optimum q
Oscillatory convergence	$0 < q < 1/2$
Oscillatory divergence	$1/2 < q < 1$
Monotonic convergence	$q < 0$
Monotonic divergence	$1 < q$

At each step, q may be calculated to give a locally optimum value by setting

$$q = \frac{x_{k+1} - x_k}{x_{k+1} - 2x_k + x_{k-1}}$$

The Method of Continuity

In the case of n equations in n unknowns, when n is large, determining the approximate solution may involve considerable effort. In such a case, the method of continuity is admirably suited for use on either digital or analog computers. It consists basically of the introduction of an extra variable into the n equations

$$f_i(x_1, x_2, \ldots, x_n) = 0, \qquad i = 1, \ldots, n$$

and replacing them by

$$f_i(x_1, x_2, \ldots, x_n, \lambda) = 0, \qquad i = 1, \ldots, n$$

where λ is introduced in such a way that the functions depend in a simple way upon λ and reduce to an easily solvable system for $\lambda = 0$ and to the original equations for $\lambda = 1$. A system of ordinary differential equations, with independent variable λ, is then constructed by differentiating with respect to λ. There results

$$\sum_{j=1}^{n} \frac{\partial f_i}{\partial x_j} \frac{dx_j}{d\lambda} + \frac{\partial f_i}{\partial \lambda} = 0$$

where $x_1, \ldots, x_n$ are considered as functions of λ. The equations are integrated, with initial conditions obtained with $\lambda = 0$, from $\lambda = 0$ to $\lambda = 1$. If the solution can be continued to $\lambda = 1$, the values of $x_1, \ldots, x_n$ for $\lambda = 1$ will be a solution of the original equations. If the integration becomes infinite, the parameter λ must be introduced in a different fashion. Integration of the differential equations (which are usually nonlinear in λ) may be accomplished on an analog computer or by digital means using techniques described in a later section entitled "Numerical Solution of Ordinary Differential Equations."

Example

$$f(x, y) = 2 + x + y - x^2 + 8xy + y^3 = 0$$

$$g(x, y) = 1 + 2x + 3y + x^2 + xy - ye^x = 0$$

Introduce λ as

$$f(x, y, \lambda) = (2 + x + y) + \lambda(-x^2 + 8xy + y^3) = 0$$

$$g(x, y, \lambda) = (1 + 2x - 3y) + \lambda(x^2 + xy - ye^x) = 0$$

For $\lambda = 1$, these reduce to the original equations, but, for $\lambda = 0$, they are the linear systems

$$x + y = -2$$

$$2x - 3y = -1$$

which has the unique solution $x = -1.4$, $y = -0.6$. The differential equations in this case become

$$\frac{\partial f}{\partial x} \frac{dx}{d\lambda} + \frac{\partial f}{\partial y} \frac{dy}{d\lambda} = -\frac{\partial f}{\partial \lambda}$$

$$\frac{\partial g}{\partial x} \frac{dx}{d\lambda} + \frac{\partial g}{\partial y} \frac{dy}{d\lambda} = -\frac{\partial g}{\partial \lambda}$$

or

$$\frac{dx}{d\lambda} = \frac{\dfrac{\partial f}{\partial y}\dfrac{\partial g}{\partial \lambda} - \dfrac{\partial f}{\partial \lambda}\dfrac{\partial g}{\partial x}}{\dfrac{\partial f}{\partial x}\dfrac{\partial g}{\partial y} - \dfrac{\partial f}{\partial y}\dfrac{\partial g}{\partial x}}$$

$$\frac{dy}{d\lambda} = \frac{\dfrac{\partial f}{\partial \lambda}\dfrac{\partial g}{\partial x} - \dfrac{\partial f}{\partial x}\dfrac{\partial g}{\partial \lambda}}{\dfrac{\partial f}{\partial x}\dfrac{\partial g}{\partial y} - \dfrac{\partial f}{\partial y}\dfrac{\partial g}{\partial x}}$$

Integrating in λ, with initial values $x = -1.4$ and $y = -0.6$ at $\lambda = 0$, from $\lambda = 0$ to $\lambda = 1$ gives the solution.

Interpolation and Finite Differences

The practicing engineer constantly finds it necessary to refer to tables as sources of information. Consequently, interpolation, or that procedure of "reading between the lines of the table," is a necessary topic in numerical analysis.

Linear Interpolation

If a function $f(x)$ is approximately linear in a certain range, then the ratio $[f(x_1) - f(x_0)]/(x_1 - x_0) = f[x_0, x_1]$ is approximately independent of x_0 and x_1 in the range. The linear approximation to the function $f(x)$, $x_0 < x < x_1$, then leads to the interpolation formula

$$f(x) \approx f(x_0) + (x - x_0) f[x_0, x_1] \approx f(x_0) + \frac{x - x_0}{x_1 - x_0}\left[f(x_1) - f(x_0)\right]$$

$$\approx \frac{1}{x_1 - x_0}\left[(x_1 - x) f(x_0) - (x_0 - x) f(x_1)\right]$$

Divided Differences of Higher Order and Higher-Order Interpolation

The first-order divided difference $f[x_0, x_1]$ was defined above. Divided differences of second and higher order are defined iteratively by

$$f[x_0, x_1, x_2] = \frac{f[x_1, x_2] - f[x_0, x_1]}{x_2 - x_0}$$

$$\vdots$$

$$f[x_0, x_1, \ldots, x_k] = \frac{f[x_1, \ldots, x_k] - f[x_0, x_1, \ldots, x_{k-1}]}{x_k - x_0}$$

and a convenient form for computational purposes is

$$f[x_0, x_1, \ldots, x_k] = \sum_{j=0}^{k}{}' \frac{f(x_j)}{(x_j - x_0)(x_j - x_1)\cdots(x_j - x_k)}$$

for any $k \geq 0$, where the $'$ means the term $(x_j - x_j)$ is omitted in the denominator. For example,

$$f\left[x_0,x_1,x_2\right]=\frac{f\left(x_0\right)}{\left(x_0-x_1\right)\left(x_0-x_2\right)}+\frac{f\left(x_1\right)}{\left(x_1-x_0\right)\left(x_1-x_2\right)}+\frac{f\left(x_2\right)}{\left(x_2-x_0\right)\left(x_2-x_1\right)}$$

If the accuracy afforded by a linear approximation is inadequate, a generally more accurate result may be based upon the assumption that $f(x)$ may be approximated by a polynomial of degree 2 or higher over certain ranges. This assumptions leads to *Newton's fundamental interpolation formula* with divided differences:

$$\begin{aligned}f(x)\approx f\left(x_0\right)+\left(x-x_0\right)f\left[x_0,x_1\right]+\left(x-x_0\right)\left(x-x_1\right)f\left[x_0,x_1,x_2\right]\\+\left(x-x_0\right)\left(x-x_1\right)\cdots\left(x-x_{n-1}\right)f\left[x_0,x_1,\ldots,x_n\right]+E_n(x)\end{aligned}$$

where $E_n(x)$ = error = $[1/(n+1)!]f^{(n-1)}(\varepsilon)\pi(x)$ where $\min(x_0, \ldots, x) < \varepsilon < \max(x_0, x_1,\ldots, x_n, x)$ and $\pi(x) = (x - x_0)(x - x_1)\ldots(x - x_n)$. In order to use this most effectively, one may first form a divided-difference table. For example, for third-order interpolation, the difference table is

$$\begin{array}{c|cccc}
x_0 & f\left(x_0\right) & & & \\
 & & f\left[x_0,x_1\right] & & \\
x_1 & f\left(x_1\right) & & f\left[x_0,x_1,x_2\right] & \\
 & & f\left[x_1,x_2\right] & & f\left[x_0,x_1,x_2,x_3\right] \\
x_2 & f\left(x_2\right) & & f\left[x_1,x_2,x_3\right] & \\
 & & f\left[x_2,x_3\right] & & \\
x_3 & f\left(x_3\right) & & &
\end{array}$$

where each entry is given by taking the difference between diagonally adjacent entries to the left, divided by the abscissas corresponding to the ordinates intercepted by the diagonals passing through the calculated entry.

Example. Calculate by third-order interpolation the value of cosh 0.83 given cosh 0.60, cosh 0.80, cosh 0.90, and cosh 1.10.

$$\begin{array}{l|llll}
x_0=0.60 & 1.185\ 47 & & & \\
 & & 0.7598 & & \\
x_1=0.80 & 1.337\ 43 & & 0.6560 & \\
 & & 0.9566 & & 0.1586 \\
x_2=0.90 & 1.433\ 09 & & 0.7353 & \\
 & & 1.1772 & & \\
x_3=1.10 & 1.668\ 52 & & &
\end{array}$$

With $n = 3$, we have

$$\begin{aligned}\cosh 0.83\approx 1.185\ 47+(0.23)(0.7598)+(0.23)(0.03)(0.6560)\\+(0.23)(0.03)(-0.07)(0.1586)=1.364\ 64\end{aligned}$$

which varies from the true value by 0.000 04.

Lagrange Interpolation Formulas

The Newton formulas are expressed in terms of divided differences. It is often useful to have interpolation formulas expressed explicitly in terms of the ordinates involved. This is accomplished by the Lagrange interpolation polynomial of degree n:

$$y(x)=\sum_{j=0}^{n}\frac{\pi(x)}{\left(x-x_j\right)\pi'\left(x_j\right)}f\left(x_j\right)$$

where

$$\pi(x) = (x - x_0)(x - x_1)\cdots(x - x_n)$$

$$\pi'(x_j) = (x_j - x_0)(x_j - x_1)\cdots(x_j - x_n)$$

where $(x_j - x_j)$ is the omitted factor. Thus,

$$f(x) = y(x) + E_n(x)$$

$$E_n(x) = \frac{1}{(n+1)!}\pi(x) f^{(n+1)}(\varepsilon)$$

Example. The interpolation polynomial of degree 3 is

$$y(x) = \frac{(x - x_1)(x - x_2)(x - x_3)}{(x_0 - x_1)(x_0 - x_2)(x_0 - x_3)} f(x_0) + \frac{(x - x_0)(x - x_2)(x - x_3)}{(x_1 - x_0)(x_1 - x_2)(x_1 - x_3)} f(x_1)$$

$$+ \frac{(x - x_0)(x - x_1)(x - x_3)}{(x_2 - x_0)(x_2 - x_1)(x_2 - x_3)} f(x_2) + \frac{(x - x_0)(x - x_1)(x - x_2)}{(x_3 - x_0)(x_3 - x_1)(x_3 - x_2)} f(x_3)$$

Thus, directly from the data

x	0	1	3	4
$f(x)$	1	1	–1	2

we have as an interpolation polynomial $y(x)$ for (x):

$$y(x) = 1 \cdot \frac{(x-1)(x-3)(x-4)}{(0-1)(0-3)(0-4)} + 1 \cdot \frac{x(x-3)(x-4)}{(1-0)(1-3)(1-4)}$$

$$-1 \cdot \frac{x(x-1)(x-4)}{(3-0)(3-1)(3-4)} + 2 \cdot \frac{(x-0)(x-1)(x-3)}{(4-0)(4-1)(4-3)}$$

Other Difference Methods (Equally Spaced Ordinates)

Backward Differences. The backward differences denoted by

$$\nabla f(x) = f(x) - f(x-h)$$

$$\nabla^2 f(x) = \nabla f(x) - \nabla f(x-h)$$

$$\dots$$

$$\nabla f^n(x) = \nabla^{n-1} f(x) - \nabla^{n-1} f(x-h)$$

are useful for calculation near the end of tabulated data.

Central Differences. The central differences denoted by

$$\delta f(x) = f\left(x + \frac{h}{2}\right) - f\left(x - \frac{h}{2}\right)$$

$$\delta^n f(x) = \delta^{n-1} f\left(x + \frac{h}{2}\right) - \delta^{n-1} f\left(x - \frac{h}{2}\right)$$

are useful for calculating at the interior points of tabulated data.

Also to be found in the literature are Gaussian, Stirling, Bessel, Everett, Comrie differences, and so forth.

Inverse Interpolation

This is the process of finding the value of the independent variable or abscissa corresponding to a given value of the function when the latter is between two tabulated values of the abscissa. One method of accomplishing this is to use Lagrange's interpolation formula in the form

$$x = \psi(y) = \sum_{j=0}^{n} \frac{\pi(y)}{\left(y - y_j\right)\pi'\left(y_j\right)} x_j$$

where x is expressed as a function of y. Other methods revolve about methods of iteration.

Numerical Differentiation

Numerical differentiation should be avoided wherever possible, particularly when data are empirical and subject to appreciable observation errors. Errors in data can affect numerical derivatives quite strongly (i.e., differentiation is a roughening process). When such a calculation must be made, it is usually desirable first to *smooth* the data to a certain extent.

The Use of Interpolation Formulas

If the data are given over equidistant values of the independent variable x, an interpolation formula, such as the Newton formula, may be used, and the resulting formula differentiated analytically. If the independent variable is not at equidistant values, then Lagrange's formulas must be used. By differentiating three- and five-point Lagrange interpolation formulas, the following differentiation formulas result for equally spaced tabular points.

Three-point Formulas. Let x_0, x_1, and x_2 be the three points

$$f'\left(x_0\right) = \frac{1}{2h}\left[-3f\left(x_0\right) + 4f\left(x_1\right) - f\left(x_2\right)\right] + \frac{h^2}{3} f'''(\varepsilon)$$

$$f'\left(x_1\right) = \frac{1}{2h}\left[-f\left(x_0\right) + f\left(x_2\right)\right] + \frac{h^2}{6} f'''(\varepsilon)$$

$$f'\left(x_2\right) = \frac{1}{2h}\left[f\left(x_0\right) - 4f\left(x_1\right) + 3f\left(x_2\right)\right] + \frac{h^2}{3} f'''(\varepsilon)$$

where the last term is an error term and $\min_j x_j < \varepsilon < \max_j x_j$.

Five-point Formulas. Let x_0, x_1, x_2, x_3, and x_4 be the five values of the equally spaced independent variable and $f_j = f(x_j)$.

$$f'\left(x_0\right) = \frac{1}{12h}\left[-25f_0 + 48f_1 - 36f_2 + 16f_3 - 3f_4\right] + \frac{h^4}{5} f^{(v)}(\varepsilon)$$

$$f'(x_1) = \frac{1}{12h}\left[-3f_0 - 10f_1 + 18f_2 - 6f_3 + f_4\right] - \frac{h^4}{20} f^{(v)}(\varepsilon)$$

$$f'(x_2) = \frac{1}{12h}\left[f_0 - 8f_1 + 8f_3 - f_4\right] + \frac{h^4}{30} f^{(v)}(\varepsilon)$$

$$f'(x_3) = \frac{1}{12h}\left[-f_0 + 6f_1 - 18f_2 + 10f_3 + 3f_4\right] - \frac{h^4}{20} f^{(v)}(\varepsilon)$$

$$f'(x_4) = \frac{1}{12h}\left[3f_0 - 16f_1 + 36f_2 - 48f_3 + 25f_4\right] + \frac{h^4}{5} f^{(v)}(\varepsilon)$$

and the last term is again an error term.

Smoothing Techniques

These techniques involve the approximation of the tabular data by a least squares fit of the data using some known functional form, usually a polynomial. In place of approximating $f(x)$ by a single least squares polynomial of degree n over the entire range of the tabulation, it is often desirable to replace each tabulated value by the value taken on by a last squares polynomial of degree n relevant to a subrange of $2M + 1$ points centered, where possible, at the point for which the entry is to be modified. Thus, each smoothed value replaces a tabulated value. Let $f_i = f(x_i)$ be the tabular points and y_j = smoothed values. A first-degree least squares with three points would be

$$y_0 = \tfrac{1}{6}\left[5f_0 + 2f_1 - f_2\right]$$

$$y_1 = \tfrac{1}{3}\left[f_0 + f_1 + f_2\right]$$

$$y_2 = \tfrac{1}{6}\left[-f_0 + 2f_1 + 5f_2\right]$$

A first-degree least squares with five points would be

$$y_0 = \tfrac{1}{5}\left[3f_0 + 2f_1 + f_2 - f_4\right]$$

$$y_1 = \tfrac{1}{10}\left[4f_0 + 3f_1 + 2f_2 + f_3\right]$$

$$y_2 = \tfrac{1}{5}\left[f_0 + f_1 + f_2 + f_3 + f_4\right]$$

$$y_3 = \tfrac{1}{10}\left[f_0 + 2f_1 + 3f_2 + 4f_3\right]$$

$$y_4 = \tfrac{1}{5}\left[-f_0 + f_2 + 2f_3 + 3f_4\right]$$

Thus, for example, if first-degree, five-point least squares are used, the central formula is used for all values except the first two and the last two, where the off-center formulas are used. A third-degree least squares with seven points would be

$$y_0 = \tfrac{1}{42}\left[39f_0 + 8f_1 - 4f_2 - 4f_3 + f_4 + 4f_5 - 2f_6\right]$$

$$y_1 = \tfrac{1}{42}\left[8f_0 + 19f_1 + 16f_2 + 6f_3 - 4f_4 - 7f_5 + 4f_6\right]$$

$$y_2 = \tfrac{1}{42}\left[-4f_0 + 16f_1 + 19f_2 + 12f_3 + 2f_4 - 4f_5 + f_6\right]$$

$$y_3 = \tfrac{1}{21}\left[-2f_0 + 3f_1 + 6f_2 + 7f_3 + 6f_4 + 3f_5 - 2f_6\right]$$

$$y_4 = \tfrac{1}{42}\left[f_0 - 4f_1 + 2f_2 + 12f_3 + 19f_4 + 16f_5 - 4f_6\right]$$

$$y_5 = \tfrac{1}{42}\left[4f_0 - 7f_1 - 4f_2 + 6f_3 + 16f_4 + 19f_5 + 8f_6\right]$$

$$y_6 = \tfrac{1}{42}\left[-2f_0 + 4f_1 + f_2 - 4f_3 - 4f_4 + 8f_5 + 39f_6\right]$$

Additional smoothing formulas may be found in the references. After the data are smoothed, any of the interpolation polynomials, or an appropriate least squares polynomial, may be fitted and the results used to obtain the derivative.

Least Squares Method

Parabolic. For five evenly spaced neighboring abscissas labeled x_{-2}, x_{-1}, x_0, x_1, and x_2, and their ordinates f_{-2}, f_{-1}, f_0, f_1, and f_2, assume a parabola is fit by least squares. There results for all interior points, except the first and last two points of the data, the formula for the numerical derivative:

$$f_0' = \frac{1}{10h}\left[-2f_{-2} - f_{-1} + f_1 + 2f_2\right]$$

For the first two data points designated by 0 and h:

$$f'(0) = \frac{1}{20h}\left[-21f(0) + 13f(h) + 17f(2h) - 9f(3h)\right]$$

$$f'(h) = \frac{1}{20h}\left[-11f(0) + 3f(h) + 7f(2h) + f(3h)\right]$$

and for the last two given by $\alpha - h$ and α:

$$f'(\alpha - h) = \frac{1}{20h}\left[-11f(\alpha) + 3f(\alpha - h) + 7f(\alpha - 2h) + f(\alpha - 3h)\right]$$

$$f'(\alpha) = \frac{1}{20h}\left[-21f(\alpha) + 13f(\alpha - h) + 17f(\alpha - 2h) - 9(\alpha - 3h)\right]$$

Quartic (Douglas-Avakian). A fourth-degree polynomial $y = a + bx + cx^2 + dx^3 + ex^4$ is fitted to seven adjacent equidistant points (spacing h) after a translation of coordinates has been made so that $x = 0$ corresponds to the central point of the seven. Thus, these may be called $-3h$, $-2h$, $-h$, 0, h, $2h$, and $3h$. Let k = coefficient h for the seven points. This is, in $-3h$, $k = -3$. Then, the coefficients for the polynomial are

$$a = \frac{524\sum f(kh) - 245\sum k^2 f(kh) + 21\sum k^4 f(kh)}{924}$$

$$b = \frac{397\sum kf(kh)}{1512h} - \frac{7\sum k^3 f(kh)}{216h}$$

$$c = \frac{-840\sum f(kh) + 679\sum k^2 f(kh) - 67\sum k^4 f(kh)}{3168h^2}$$

$$d = \frac{-7\sum kf(kh) + \sum k^3 f(kh)}{216h^3}$$

$$e = \frac{72\sum f(kh) - 67\sum k^2 f(kh) + 7\sum k^4 f(kh)}{3168h^4}$$

where all summations run from $k = -3$ to $k = +3$ and $f(kh)$ = tabular value at kh. The slope of the polynomial at $x = 0$ is $dy/dx = b$.

Numerical Integration

Numerical evaluation of the finite integral $\int_a^b f(x)\,dx$ is carried out by a variety of methods. A few are given here.

Newton-Cotes Formulas (Equally Spaced Ordinates)

Trapezoidal Rule. This formula consists of subdividing the interval $a \le x \le b$ into n subintervals a to $a + h$, $a + h$ to $a + 2h$, …, and replacing the graph of $f(x)$ by the result of joining the ends of adjacent ordinates by line segments. If $f_j = f(x_j) = f(a + jh)$, $f_0 = f(a)$, and $f_n = f(b)$, the integration formula is

$$\int_a^b f(x)\,dx = \frac{h}{2}\left[f_0 + 2f_1 + 2f_2 + \cdots + 2f_{n-1} + f_n\right] + E_n$$

where $|E_n| = (nh^3/12)|f''(\varepsilon)| = [(b-a)^3/12n^2]|f''(\varepsilon)|$, $a < \varepsilon < b$. This procedure is not of high accuracy. However, if $f''(x)$ is continuous in $a < x < b$, the error goes to zero as $1/n^2$, $n \to \infty$.

Parabolic Rule (Simpson's Rule). This procedure consists of subdividing the interval $a < x < b$ into $n/2$ subintervals, each of length $2h$, where n is an even integer. Using the notation as above the integration formula is

$$\int_a^b f(x)\,dx = \frac{h}{3}\left[f_0 + 4f_1 + 2f_2 + 4f_3 + \cdots + 4f_{n-3} + 2f_{n-2} + 4f_{n-1} + f_n\right] + E_n$$

where

$$|E_n| = \frac{nh^5}{180}\left|f^{(iv)}(\varepsilon)\right| = \frac{(b-a)^3}{180n^4}\left|f^{(iv)}(\varepsilon)\right| \qquad a < \varepsilon < b$$

This method approximates $f(x)$ by a parabola on each subinterval. This rule is generally more accurate than the trapezoidal rule. It is the most widely used integration formula.

Weddle's Rule. This procedure consists of subdividing the integral $a < x < b$ into $n/6$ subintervals, each of length $6h$, where n is a multiple of 6. Using the notation from the trapezoidal rule, there results

$$\int_a^b f(x)\,dx = \frac{3h}{10}\left[f_0 + 5f_1 + f_2 + 6f_3 + f_4 + 5f_5 + 2f_6 + 5f_7 + f_8 + \cdots + 6f_{n-3} + f_{n-2} + 5f_{n-1} + f_n\right] + E_n$$

Note that the coefficients of f_j follow the rule 1, 5, 1, 6, 1, 5, 2, 5, 1, 6, 1, 5, 2, 5, etc.… This procedure consists of approximately $f(x)$ by a polynomial of degree 6 on each subinterval. Here,

$$E_n = \frac{nh^7}{1400}\left[10f^{(6)}(\varepsilon_1) + 9h^2 f^{(8)}(\varepsilon_2)\right]$$

Gaussian Integration Formulas (Unequally Spaced Abscissas)

These formulas are capable of yielding comparable accuracy with fewer ordinates than the equally spaced formulas. The ordinates are obtained by optimizing the distribution of the abscissas rather than by arbitrary choice. For the details of these formulas, Hildebrand (1956) is an excellent reference.

Two-Dimensional Formula

Formulas for two-way integration over a rectangle, circle, ellipse, and so forth, may be developed by a double application of one-dimensional integration formulas. The two-dimensional generalization of the parabolic rule is given here. Consider the iterated integral $\int_a^b \int_c^d f(x, y)\,dx\,dy$. Subdivide $c < x < d$ into m (even) subintervals of length $h = (d - c)/m$, and $a < y < b$ into n (even) subintervals of length $k = (b - a)/n$. This gives a subdivision of the rectangle $a \le y \le b$ and $c \le x \le d$ into subrectangles. Let $x_j = c + jh$, $y_j = a + jk$, and $f_{i,j} = f(x_i, y_j)$. Then,

$$\int_a^b \int_c^d f(x,y)\,dx\,dy = \frac{hk}{9}\Big[\left(f_{0,0} + 4f_{1,0} + 2f_{2,0} + \cdots + f_{m,0}\right) + 4\left(f_{0,1} + 4f_{1,1} + 2f_{2,1} + \cdots + f_{m,1}\right)$$

$$+ 2\left(f_{0,2} + 4f_{1,2} + 2f_{2,2} + \cdots + f_{m,2}\right) + \cdots + \left(f_{0,n} + 4f_{1,n} + 2f_{2,n} + \cdots + f_{m,n}\right)\Big] + E_{m,n}$$

where

$$E_{m,n} = -\frac{hk}{90}\left[mh^4 \frac{\partial^4 f(\varepsilon_1, \eta_1)}{\partial x^4} + nk^4 \frac{\partial^4 f(\varepsilon_2, \eta_2)}{\partial y^4}\right]$$

where ε_1 and ε_2 lie in $c < x < d$, and η_1 and η_2 lie in $a < y < b$.

Numerical Solution of Ordinary Differential Equations

A number of methods have been devised to solve ordinary differential equations numerically. The general references contain some information. A numerical solution of a differential equation means a table of values of the function y and its derivatives over only a limited part of the range of the independent variable. Every differential equation of order n can be rewritten as n first-order differential equations. Therefore, the methods given below will be for first-order equations, and the generalization to simultaneous systems will be developed later.

The Modified Euler Method

This method is simple and yields modest accuracy. If extreme accuracy is desired, a more sophisticated method should be selected. Let the first-order differential equation be $dy/dx = f(x, y)$ with the initial condition (x_0, y_0) (i.e., $y = y_0$ when $x = x_0$). The procedure is as follows.

Step 1. From the given initial conditions (x_0, y_0) compute $y_0' = f(x_0, y_0)$ and $y_0'' = [\partial f(x_0, y_0)/\partial x] + [\partial f(x_0, y_0)/\partial y]\; y_0'$. Then, determine $y_1 = y_0 + h\; y_0' + (h^2/2)\; y_0''$, where h = subdivision of the independent variable.

Step 2. Determine $y_1' = f(x_1, y_1)$ where $x_1 = x_0 + h$. These prepare us for the following.

Predictor Steps.

Step 3. For $n \geq 1$, calculate $(y_{n+1})_1 = y_{n-1} + 2h\, y_n'$.

Step 4. Calculate $(y_{n+1}')_1 = f[x_{n+1}, (y_{n+1})_1]$.

Corrector Steps.

Step 5. Calculate $(y_{n+1})_2 = y_n + (h/2)\,[(y_{n+1}')_1 + y_n']$, where y_n and y_n' without the subscripts are the previous values obtained by this process (or by steps 1 and 2).

Step 6. $(y_{n+1}')_2 = f[x_{n+1}, (y_{n+1})_2]$.

Step 7. Repeat the corrector steps 5 and 6 if necessary until the desired accuracy is produced in y_{n+1}, y_{n+1}'.

Example. Consider the equation $y' = 2y^2 + x$ with the initial conditions $y_0 = 1$ when $x_0 = 0$. Let $h = 0.1$. A few steps of the computation are illustrated.

Step	
1	$y_0' = 2y_0^2 + x_0 = 2$
	$y_0'' = 1 + 4y_0 y_0' = 1 + 8 = 9$
	$y_1 = 1 + (0.1)(2) + \left[(0.1)^2/2\right]9 = 1.245$
2	$y_1' = 2y_1^2 + x_1 = 3.100 + 0.1 = 3.200$
3	$(y_2)_1 = y_0 + 2hy_1' = 1 + 2(0.1)3.200 = 1.640$
4	$(y_2')_1 = 2(y_2)_1^2 + x_2 = 5.592$
5	$(y_2)_2 = y_1 + (0.1/2)\left[(y_2')_1 + y_1'\right] = 1.685$
6	$(y_2')_2 = 2(y_2)_2^2 + x_2 = 5.878$
5 (repeat)	$(y_2)_3 = y_1 + (0.05)\left[(y_2')_2 + y_1'\right] = 1.699$
6 (repeat)	$(y_2')_3 = 2(y_2)_3^2 + x_2 = 5.974$

and so forth. This procedure. may be programmed for a computer. A discussion of the truncation error of this process may be found in Milne (1953).

Modified Adam's Method

The procedure given here was developed retaining third differences. It can then be considered as a more exact predictor-corrector method than the Euler method. The procedure is as follows for $dy/dx = f(x, y)$ and h = interval size.

Steps 1 and 2 are the same as in Euler method.

Predictor Steps.

Step 3. $(y_{n+1})_1 = y_n + (h/24)\,[55y_n' - 59y_{n-1}' + 37y_{n-2}' - 9y_{n-3}']$, where y_n', y_{n-1}', etc…, are calculated in step 1.

Step 4. $(y_{n+1}')_1 = f[x_{n+1}, (y_{n+1})_1]$.

Corrector Steps.

Step 5. $(y_{n+1})_2 = y_n + (h/24)\,[9(y'_{n+1})_1 + 19y'_n - 5y'_{n-1} + y'_{n-2}]$.
Step 6. $(y'_{n+1})_2 = f[x_{n+1}, (y_{n+1})_2]$.
Step 7. Iterate steps 5 and 6 if necessary.

Runge-Kutta Methods

These methods are self-starting and are inherently stable. Kopal (1955) is a good reference for their derivation and discussion. Third- and fourth-order procedures are given below for $dy/dx = f(x, y)$ and h = interval size.

For third-order (error ≈ h^4).

$$k_0 = hf(x_n, y_n)$$

$$k_1 = hf(x_n + \tfrac{1}{2}h, y_n + \tfrac{1}{2}k_0)$$

$$k_2 = hf(x_n + h, y_n + 2k_1 - k_0)$$

and

$$y_{n+1} = y_n + \tfrac{1}{6}(k_0 + 4k_1 + k_2)$$

for all $n \geq 0$, with initial condition (x_0, y_0).

For fourth-order (error ≈ h^5),

$$k_0 = hf(x_n, y_n)$$

$$k_1 = hf(x_n + \tfrac{1}{2}h, y_n + \tfrac{1}{2}k_0)$$

$$k_2 = hf(x_n + \tfrac{1}{2}h, y_n + \tfrac{1}{2}k_1)$$

$$k_3 = hf(x_n + h, y_n + k_2)$$

and

$$y_{n+1} = y_n + \tfrac{1}{6}(k_0 + 2k_1 + 2k_2 + k_3)$$

Example. (Third-order) Let $dy/dx = x - 2y$, with initial condition $y_0 = 1$ when $x_0 = 0$, and let $h = 0.1$. Clearly, $x_n = nh$. To calculate y_1, proceed as follows:

$$k_0 = 0.1[x_0 - 2y_0] = -0.2$$

$$k_1 = 0.1[0.05 - 2(1 - 0.1)] = -0.175$$

$$k_2 = 0.1[0.1 - 2(1 - 0.35 + 0.2)] = -0.16$$

$$y_1 = 1 + \tfrac{1}{6}(-0.2 - 0.7 - 0.16) = 0.8234$$

Equations of Higher Order and Simultaneous Differential Equations

Any differential equation of second- or higher order can be reduced to a simultaneous system of first-order equations by the introduction of auxiliary variables. Consider the following equations:

$$\frac{d^2x}{dt^2} + xy\frac{dx}{dt} + z = e^x$$

$$\frac{d^2y}{dt^2} + xy\frac{dy}{dt} = 7 + t^2$$

$$\frac{d^2z}{dt^2} + xz\frac{dz}{dt} + x = e^x$$

In the new variables $x_1 = x$, $x_2 = y$, $x_3 = z$, $x_4 = dx_1/dt$, $x_5 = dx_2/dt$, and $x_6 = dx_3/dt$, the equations become

$$\frac{dx_1}{dt} = x_4$$

$$\frac{dx_2}{dt} = x_5$$

$$\frac{dx_3}{dt} = x_6$$

$$\frac{dx_4}{dt} = -x_1x_2x_4 - x_3 + e^{x_3}$$

$$\frac{dx_5}{dt} = -x_3x_2x_5 + 7 + t^2$$

$$\frac{dx_6}{dt} = -x_1x_3x_6 - x_1 + e^{x_1}$$

which is a system of the general form

$$\frac{dx_i}{dt} = f_i\left(t, x_1, x_2, x_3, \ldots, x_n\right)$$

where $i = 1, 2, \ldots, n$. Such systems may be solved by simultaneous application of any of the above numerical techniques. A Runge-Kutta method for

$$\frac{dx}{dt} = f\left(t, x, y\right)$$

$$\frac{dy}{dt} = g\left(t, x, y\right)$$

is given below. The fourth-order procedure is shown.

Starting at the initial conditions x_0, y_0, and t_0, the next values x_1 and y_1 are computed via the equations below (where $\Delta t = h$, $t_j = h + t_{j-1}$):

$$k_0 = hf(t_0, x_0, y_0) \qquad l_0 = hg(t_0, x_0, y_0)$$

$$k_1 = hf\left(t_0 + \frac{h}{2}, x_0 + \frac{k_0}{2}, y_0 + \frac{l_0}{2}\right) \qquad l_1 = hg\left(t_0 + \frac{h}{2}, x_0 + \frac{k_0}{2}, y_0 + \frac{l_0}{2}\right)$$

$$k_2 = hf\left(t_0 + \frac{h}{2}, x_0 + \frac{k_1}{2}, y_0 + \frac{l_1}{2}\right) \qquad l_2 = hg\left(t_0 + \frac{h}{2}, x_0 + \frac{k_1}{2}, y_0 + \frac{l_1}{2}\right)$$

$$k_3 = hf(t_0 + h, x_0 + k_2, y_0 + l_2) \qquad l_3 = hg(t_0 + h, x_0 + k_2, y_0 + l_2)$$

and

$$x_1 = x_0 + \tfrac{1}{6}(k_0 + 2k_1 + 2k_2 + k_3)$$

$$y_1 = y_0 + \tfrac{1}{6}(l_0 + 2l_1 + 2l_2 + l_3)$$

To continue the computation, replace t_0, x_0, and y_0 in the above formulas by $t_1 = t_0 + h$, x_1, and y_1 just calculated. Extension of this method to more than two equations follows precisely this same pattern.

Numerical Solution of Integral Equations

This section considers a method of numerically solving the Fredholm integral equation of the second kind:

$$u(x) = f(x) + \lambda \int_a^b k(x,t)u(t)\,dt \qquad \text{for } u(x)$$

The method discussed arises because a definite integral can be closely approximated by any of several numerical integration formulas (each of which arises by approximating the function by some polynomial over an interval). Thus, the definite integral can be replaced by an integration formula which becomes

$$u(x) = f(x) + \lambda(b-a)\left[\sum_{i=1}^{n} c_i k(x, t_i) u(t_i)\right]$$

where $t_1, \ldots, t_n$ are points of subdivision of the t axis, $a \le t \le b$, and the *cs* are coefficients whose values depend upon the type of numerical integration formula used. Now, this must hold for all values of x, where $a \le x \le b$; so it must hold for $x = t_1$, $x = t_2, \ldots, x = t_n$. Substituting for x successively $t_1, t_2, \ldots, t_n$, and setting $u(t_i) = u_i$ and $f(t_i) = f_i$, we get n linear algebraic equations for the n unknowns $u_1, \ldots, u_n$. That is,

$$u_i = f_i + (b-a)\left[c_1 k(t_i, t_1) u_1 + c_2 k(t_i, t_2) u_2 + \cdots + c_n k(t_i, t_n) u_n\right], \qquad i = 1, 2, \ldots, n$$

These u_j may be solved for by the methods under the section entitled “Numerical Solution of Linear Equations.”

Numerical Methods for Partial Differential Equations

The ultimate goal of numerical (discrete) methods for partial differential equations (PDEs) is the reduction of continuous systems (projections) to discrete systems that are suitable for high-speed computer solutions. The user must be cautioned that the seeming elementary nature of the techniques holds pitfalls that can be seriously misleading. These approximations often lead to difficult mathematical questions of adequacy, accuracy, convergence, stability, and consistency. Convergence is concerned with the approach of the approximate numerical solution to the exact solution as the number of mesh units increase indefinitely in some sense. Unless the numerical method can be shown to converge to the exact solution, the chosen method is unsatisfactory.

Stability deals in general with error growth in the calculation. As stated before, any numerical method involves truncation and round-off errors. These errors are not serious unless they grow as the computation proceeds (i.e., the method is unstable).

Finite Difference Methods

In these methods, the derivatives are replaced by various finite differences. The methods will be illustrated for problems in two space dimensions (x, y) or (x, t) where t is timelike. Using subdivisions $\Delta x = h$ and $\Delta y = k$ with $u(i\,h, jk) = u_{i,j}$, approximate $u_x|_{i,j} = [(u_{i+1,j} - u_{i,j})/h] + O(h)$ (forward difference), a first-order $[O(h)]$ method, or $u_x|_{i,j} = [(u_{i+1,j} - u_{i-1,j})/2h] + O(h^2)$ (central difference), a second-order method. The second derivative is usually approximated with the second-order method $[u_{xx}|_{i,j} = [(u_{i+1,j} - 2u_{i,j} + u_{i-1,j})/h^2] + O(h^2)]$.

Example. Using second-order differences for u_{xx} and u_{yy}, the five-point difference equation (with $h = k$) for Laplace's equation $u_{xx} + u_{yy} = 0$ is $u_{i,j} = 1/4[u_{i+1,j} + u_{i-1,j} + u_{i,j+1} + u_{i,j-1}]$. The accuracy is $O(h^2)$. This model is called *implicit* because one must solve for the total number of unknowns at the unknown grid points (i, j) in terms of the given boundary data. In this case, the system of equations is a linear system.

Example. Using a forward-difference approximation for u_t and a second-order approximation for u_{xx}, the diffusion equation $u_t = u_{xx}$ is approximated by the *explicit* formula $u_{i,j+1} = ru_{i-1,j} + (1 - 2r)u_{i,j} + ru_{i+1,j}$. This classic result permits step-by-step advancement in the t direction beginning with the initial data at $t = 0$ $(j = 0)$ and guided by the boundary data. Here, the term $r = \Delta t/(\Delta x)^2 = k/h^2$ is restricted to be less than or equal to 1/2 for stability and the truncation error is $O(k^2 + kh^2)$.

The Crank-Nicolson implicit formula which approximates the diffusion equation $u_t = u_{xx}$ is

$$-r\lambda u_{i-1,j+1} + (1 + 2r\lambda)u_{i,j+1} - r\lambda u_{i+1,j+1} = r(1-\lambda)u_{i-1,j} + [1 - 2r(1-\lambda)]u_{i,j} + r(1-\lambda)u_{i+1,j}$$

The stability of this numerical method was analyzed by Crandall (Ames, 1993) where the λ, r stability diagram is given.

Approximation of the time derivative in $u_t = u_{xx}$ by a central difference leads to an always unstable approximation — the useless approximation

$$u_{i,j+1} = u_{i,j-1} + 2r(u_{i+1,j} - 2u_{i,j} + u_{i-1,j})$$

which is a warning to be careful.

The foregoing method is *symmetric* with respect to the point (i, j), where the method is centered. Asymmetric methods have some computational advantages, so the Saul'yev method is described (Ames, 1993). The algorithms $(r = k/h^2)$

$$(1 + r)u_{i,j+1} = u_{i,j} + r(u_{i-1,j+1} - u_{i,j} + u_{i+1,j}) \qquad \text{(Saul' yev A)}$$

$$(1 + r)u_{i,j+1} = u_{i,j} + r(u_{i+1,j+1} - u_{i,j} + u_{i-1,j}) \qquad \text{(Saul' yev B)}$$

are used as in any one of the following options:

1. Use Saul'yev A only and proceed line-by-line in the $t(j)$ direction, but *always* from the left boundary on a line.
2. Use Saul'yev B only and proceed line-by-line in the $t(j)$ direction, but *always* from the right boundary to the left on a line.

3. Alternate from line to line by first using Saul'yev A and then B, or the reverse. This is related to *alternating direction methods.*
4. Use Saul'yev A and Saul'yev B on the same line and average the results for the final answer (A first, and then B). This is equivalent to introducing the dummy variables $P_{i,j}$ and $Q_{i,j}$ such that

$$(1+r)P_{i,j+1} = U_{i,j} + r\left(P_{i-1,j+1} - U_{i,j} + U_{i+1,j}\right)$$

$$(1+r)Q_{i,j+1} = U_{i,j} + r\left(Q_{i+1,j+1} - U_{i,j} + U_{i-1,j}\right)$$

and

$$U_{i,j+1} = \tfrac{1}{2}\left(P_{i,j+1} + Q_{i,j+1}\right)$$

This averaging method has some computational advantage because of the possibility of truncation error cancellation. As an alternative, one can retain the $P_{i,j}$ and $Q_{i,j}$ from the previous step and replace $U_{i,j}$ and $U_{i+1,j}$ by $P_{i,j}$ and $P_{i+1,j}$, respectively, and $U_{i,j}$ and $U_{i-1,j}$ by $Q_{i,j}$ and $Q_{i-1,j}$, respectively.

Weighted Residual Methods (WRMs)

To set the stage for the method of finite elements, we briefly describe the WRMs, which have several variations — the interior, boundary, and mixed methods. Suppose the equation is $Lu = f$, where L is the partial differential operator and f is a known function, of say x and y. The first step in WRM is to select a class of known basis functions b_i (e.g., trigonometric, Bessel, Legendre) to approximate $u(x, y)$ as ~ $\Sigma\, a_i\, b_i\,(x, y) = U(x, y, a)$. Often, the b_i are selected so that $U(x, y, a)$ satisfy the boundary conditions. This is essentially the *interior method.* If the b_i, in $U(x, y, a)$ are selected to satisfy the differential equations, but not the boundary conditions, the variant is called the *boundary method.* When neither the equation nor the boundary conditions are satisfied, the method is said to be *mixed.* The least ingenuity is required here. The usual method of choice is the interior method.

The second step is to select an optimal set of constants a_i, $i = 1,2, \ldots, n$, by using the residual $R_I(U) = LU - f$. This is done here for the interior method. In the boundary method, there are a set of boundary residual R_B, and, in the mixed method. Both R_I and R_B. Using the spatial average $(w, v) = \int_v wv dV$, the criterion for selecting the values of a_i is the requirement that the n spatial averages

$$\left(b_i, R_E(U)\right) = 0, \qquad i = 1,2,\ldots,n$$

These represent n equations (linear if the operator L is linear and nonlinear otherwise) for the a_i.

Particular WRMs differ because of the choice of the b_js. The most common follow.

1. *Subdomain* The domain V is divided into n smaller, not necessarily disjoint, subdomains V_j with $w_j(x, y) = 1$ if (x, y) is in V_j, and 0 if (x, y) is not in V_j.
2. *Collocation* Select n points $P_j = (x_j, y_j)$ in V with $w_j(P_j) = \delta(P - P_j)$, where $\int_v \phi(P)\delta(P - P_j)dP = \phi(P_j)$ for all test functions $\phi(P)$ which vanish outside the compact set V. Thus, $(w_j, R_E) = \int_v \delta(P - P_j)R_E dV = R_E[U(P_j) \equiv 0$ (i.e., the residual is set equal to zero at the n points P_j).
3. *Least squares* Here, the functional $I(a) = \int_V R_E^2\, dV$, where $a = (a_1, \ldots, a_n)$, is to be made stationary with respect to the a_j. Thus, $0 = \partial I/\partial a_j = 2\int_v R_E(\partial R_E/\partial a_j)dV$, with $j = 1, 2, \ldots, n$. The w_j in this case are $\partial R_E/\partial a_j$.
4. *Bubnov-Galerkin* Choose $w_j(P) = b_j(P)$. This is perhaps the best-known method.
5. *Stationary Functional (Variational) Method* With ϕ a variational integral (or other functional), set $\partial\phi[U]/\partial a_j = 0$, where $j = 1, \ldots, n$, to generate the n algebraic equations.

Example. $u_{xx} + u_{yy} = -2$, with $u = 0$ on the boundaries of the square $x = \pm 1$, $y = \pm 1$. Select an interior method with $U = a_1(1 - x^2)(1 - y^2) + a_2 x^2 y^2 (1 - x^2)(1 - y^2)$, whereupon the residual $R_E(U) = 2a_1(2 - x^2 - y^2) + 2a_2[(1 - 6x^2)y^2(1 - y^2) + (1 - 6y^2) - (1 - x^2)] + 2$. Collocating at (1/3, 1/3) and (2/3, 2/3) gives the two linear equations $-32a_1/9 + 32a_2/243x^2 + 2 = 0$ and $-20a_1/9 - 400a_2/243 + 2 = 0$ for a_1 and a_2.

WRM methods can obviously be used as approximate methods. We have now set the stage for *finite elements.*

Finite Elements

The WRM methods are more general than the *finite elements* (FE) methods. FE methods require, in addition, that the basis functions be finite elements (i.e., functions that are zero except on a small part of the domain under consideration). A typical example of an often used basis is that of triangular elements. For a triangular element with Cartesian coordinates (x_1, y_1), (x_2, y_2), and (x_3, y_3), define natural coordinates L_1, L_2, and L_3 (L_i, $\leftrightarrow (x_i, y_i)$) so that $L_i = A_i/A$ where

$$A = \tfrac{1}{2}\det\begin{bmatrix} 1 & x_1 & y_1 \\ 1 & x_2 & y_2 \\ 1 & x_3 & y_3 \end{bmatrix}$$

is the area of the triangle and

$$A_1 = \tfrac{1}{2}\det\begin{bmatrix} 1 & x & y \\ 1 & x_2 & y_2 \\ 1 & x_3 & y_3 \end{bmatrix}$$

$$A_2 = \tfrac{1}{2}\det\begin{bmatrix} 1 & x_1 & y_1 \\ 1 & x & y \\ 1 & x_3 & y_3 \end{bmatrix}$$

$$A_3 = \tfrac{1}{2}\det\begin{bmatrix} 1 & x_1 & y_1 \\ 1 & x_2 & y_2 \\ 1 & x & y \end{bmatrix}$$

Clearly $L_1 + L_2 + L_3 = 1$, and the L_i are one at node i and zero at the other nodes. In terms of the Cartesian coordinates,

$$\begin{bmatrix} L_1 \\ L_2 \\ L_3 \end{bmatrix} = \frac{1}{2A}\begin{bmatrix} x_2 y_3 - x_3 y_2, & y_2 - y_3, & x_3 - x_2 \\ x_3 y_1 - x_1 y_3, & y_3 - y_1, & x_1 - x_3 \\ x_1 y_2 - x_2 y_1, & y_1 - y_2, & x_2 - x_1 \end{bmatrix}\begin{bmatrix} 1 \\ x \\ y \end{bmatrix}$$

is the linear triangular element relation.

Tables of linear, quadratic, and cubic basis functions are given in the literature. Notice that while the linear basis needs three nodes, the quadratic requires six and the cubic basis ten. Various modifications, such as the Hermite basis, are described in the literature. Triangular elements are useful in approximating irregular domains.

For rectangular elements, the *chapeau* functions are often used. Let us illustrate with an example. Let $u_{xx} + u_{yy} = Q$, $0 < x < 2$, $0 < y < 2$, $u(x, 2) = 1$, $u(0, y) = 1$, $u_y(x, 0) = 0$, $u_x(2, y) = 0$, and $Q(x, y) = Qw\delta(x - 1)\delta(y - 1)$,

$$\delta(x) = \begin{cases} 0 & x \neq 0 \\ 1 & x = 0 \end{cases}$$

Using four equal rectangular elements, map the element I with vertices at (0, 0) (0, 1), (1, 1), and (1, 0) into the local (canonical) coordinates (ξ, η), $-1 \le \xi \le 1$, $-1 \le \eta \le 1$, by means of $x = 1/2(\xi + 1)$, $y = 1/2(\eta + 1)$. This mapping permits one to develop software that standardizes the treatment of all elements. Converting to (ξ, η) coordinates, our problem becomes $u_{\xi\xi} + u_{\eta\eta} = 1/4Q$, $-1 \le \xi \le 1$, $-1 \le \eta \le 1$, $Q = Qw\delta(\xi - 1)\delta(\eta - 1)$.

First, a trial function $\bar{u}\ (\xi, \eta)$ is defined as $u(\xi, \eta) \approx \bar{\mu}\ (\xi, \eta) = \Sigma_{j=1}^{4} A_j\phi_j(\xi, \eta)$ (in element I) where the ϕ_j are the two-dimensional chapeau functions

$$\phi_1 = \left[\tfrac{1}{2}(1-\xi)\tfrac{1}{2}(1-\eta)\right] \qquad \phi_2 = \left[\tfrac{1}{2}(1+\xi)\tfrac{1}{2}(1-\eta)\right]$$

$$\phi_3 = \left[\tfrac{1}{2}(1+\xi)\tfrac{1}{2}(1+\eta)\right] \qquad \phi_4 = \left[\tfrac{1}{2}(1-\xi)\tfrac{1}{2}(1+\eta)\right]$$

Clearly ϕ_i take the value one at node i, provide a bilinear approximation, and are nonzero only over elements adjacent to node i.

Second, the equation residual $R_E = \nabla^2 \bar{u} - 1/4Q$ is formed and a WRM procedure is selected to formulate the algebraic equations for the A_i. This is indicated using the Galerkin method. Thus, for element I, we have

$$\iint_{D_I} \left(\bar{u}_{\xi\xi} + \bar{u}_{\eta\eta} - Q\right)\phi_i(\xi,\eta)\, d\xi\, d\eta = 0, \qquad i = 1,\ldots,4$$

Applying Green's theorem, this result becomes

$$\iint_{D_I} \left[\bar{u}_\xi(\phi_i)_\xi + \bar{u}_\eta(\phi_i)_\eta + \tfrac{1}{4}Q\phi_i\right] d\xi\, d\eta - \int_{\partial D_I} \left(\bar{u}_\xi c_\xi + \bar{u}_\eta c_\eta\right)\phi_i\, ds = 0, \qquad i = 1,2,\ldots,4$$

Using the same procedure in all four elements and recalling the property that the ϕ_i in each element are nonzero only over elements adjacent to node i gives the following nine equations:

$$\sum_{e=1}^{4}\left\{\iint_{D_e}\sum_{j=1}^{9} A_j\left[(\phi_j)_\xi(\phi_i)_\xi + (\phi_j)_\eta(\phi_i)_\eta\right] + \tfrac{1}{4}Q\phi_i\right\} d\xi\, d\eta$$

$$-\sum_{e=1}^{4}\int_{\partial D_e}\left(\bar{u}_\xi c_\xi + \bar{u}_\eta c_\eta\right)\phi\, ds = 0, \quad n = 1,2,\ldots,9$$

where the c_ξ and c_η are the direction cosines of the appropriate element (e) boundary.

Method of Lines

The *method of lines,* when used on PDEs in two dimensions, reduces the PDE to a system of ordinary differential equations (ODEs), usually by finite difference or finite element techniques. If the original problem is an initial value (boundary value) problem, then the resulting ODEs form an initial value (boundary value) problem. These ODEs are solved by ODE numerical methods.

Example. $u_t = u_{xx} + u^2$, $0 < x < 1$, $0 < t$, with the initial value $u(x, 0) = x$, and boundary data $u(0, t) = 0$, $u(1, t) = \sin t$. A discretization of the space variable (x) is introduced and the time variable is left continuous. The approximation is $\dot{u}_i = (u_{i+1} - 2u_i + u_{i-1})/h^2 + u_i^2$. With $h = 1/5$, the equations become

$$\begin{aligned}
u_0(t) &= 0 \\
\dot{u}_1 &= \tfrac{1}{25}\left[u_2 - 2u_1\right] + u_1^2 \\
\dot{u}_2 &= \tfrac{1}{25}\left[u_3 - 2u_2 + u_1\right] + u_2^2 \\
\dot{u}_3 &= \tfrac{1}{25}\left[u_4 - 2u_3 + u_2\right] + u_3^2 \\
\dot{u}_4 &= \tfrac{1}{25}\left[\sin t - 2u_4 + u_3\right] + u_4^2 \\
u_5 &= \sin t
\end{aligned}$$

and $u_1(0) = 0.2$, $u_2(0) = 0.4$, $u_3(0) = 0.6$, and $u_4(0) = 0.8$.

Discrete and Fast Fourier Transforms

Let $x(n)$ be a sequence that is nonzero only for a finite number of samples in the interval $0 \le n \le N - 1$. The quantity

$$X(k) = \sum_{n=0}^{N-1} x(n) e^{-i(2\pi/N)nk}, \quad k = 0, 1, \ldots, N - 1$$

is called the *discrete Fourier transform* (DFT) of the sequence $x(n)$. Its inverse (IDFT) is given by

$$x(n) = \frac{1}{N} \sum_{k=0}^{N-1} X(k) e^{i(2\pi/N)nk}, \quad n = 0, 1, \ldots, N - 1 \quad \left(i^2 = -1\right)$$

Clearly, DFT and IDFT are finite sums and there are N frequency values. Also, $X(k)$ is periodic in k with period N.

Example. $x(0) = 1$, $x(1) = 2$, $x(2) = 3$, $x(3) = 4$

$$X(k) = \sum_{n=0}^{3} x(n) e^{-i(2\pi/4)nk}, \quad k = 0,\ 1,\ 2,\ 3,\ 4$$

Thus,

$$X(0) = \sum_{n=0}^{3} x(n) = 10$$

and $X(1) = x(0) + x(1)e^{-i\pi/2} + x(2)e^{-i\pi} + x(3)e^{-i3\pi/2} = 1 - 2i - 3 + 4i = -2 + 2i$; $X(2) = -2$; $X(3) = -2 - 2i$.

DFT Properties

1. Linearity: If $x_3(n) = ax_1(n) + bx_2(n)$, then $X_3(k) = aX_1(k) + bX_2(k)$.
2. Symmetry: For $x(n)$ real, $\mathrm{Re}[X(k)] = \mathrm{Re}[X(N - k)]$, $\mathrm{Im}[(k)] = -\mathrm{Im}[X(N - k)]$.

3. Circular shift: By a circular shift of a sequence defined in the interval $0 \le n \le N-1$, we mean that, as values *fall off* from one end of the sequence, they are appended to the other end. Denoting this by $x(n \oplus m)$, we see that positive m means shift left and negative m means shift right. Thus, $x_2(n) = x_1(n \oplus m) \Leftrightarrow X_2(k) = X_1(k)e^{i(2\pi/N)km}$.
4. Duality: $x(n) \Leftrightarrow X(k)$ implies $(1/N)X(n) \Leftrightarrow x(-k)$.
5. Z-transform relation: $X(k) = X(z)\big|_{z=e^{i(2\pi k/N)}}$, $k = 0, 1, \ldots, N-1$.
6. Circular convolution: $x_3(n) = \Sigma_{m=0}^{N-1} x_1(m)x_2(n \ominus m) = \Sigma_{\ell=0}^{N-1} x_1(n \ominus \ell)x_2(\ell)$ where $x_2(n \ominus m)$ corresponds to a circular shift to the right for positive m.

One fast algorithm for calculating DFTs is the radix-2 *fast Fourier transform* developed by J. W. Cooley and J. W. Tucker. Consider the two-point DFT $X(k) = \Sigma_{n=0}^{1} x(n)e^{-i(2\pi/2)nk}$, $k = 0, 1$. Clearly, $X(k) = x(0) + x(1)e^{-i\pi k}$. So, $X(0) = x(0) + x(1)$ and $X(1) = x(0) - x(1)$. This process can be extended to DFTs of length $N = 2^r$, where r is a positive integer. For $N = 2^r$, decompose the N-point DFT into *two* $N/2$-point DFTs. Then, decompose each $N/2$-point DFT into *two* $N/4$-point DFTs, and so on until eventually we have $N/2$ *two*-point DFTs. Computing these as indicated above, we combine them into $N/4$ four-point DFTs and then $N/8$ eight-point DFTs, and so on, until the DFT is computed. The total number of DFT operations (for large N) is $O(N^2)$, and that of the FFT is $O(N \log_2 N)$, quite a saving for large N.

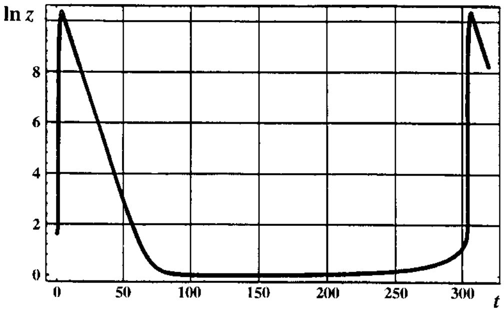

Figure 19.12.1

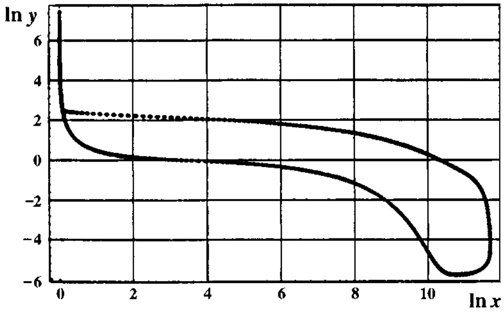

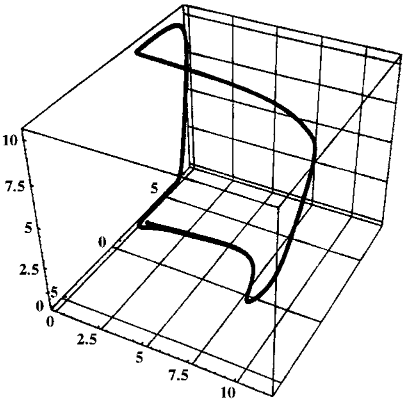

Figure 19.12.2

Figure 19.12.3

FIGURES 19.12.1 to 19.12.3 The "Oregonator" is a periodic chemical reaction describable by three nonlinear first-order differential equations. The results (Figure 19.12.1) illustrate the periodic nature of the major chemical vs. time. Figure 19.12.2 shows the phase diagram of two of the reactants, and Figure 19.12.3 is the three-dimensional phase diagram of all reactants. The numerical computation was done using a fourth-order Runge-Kuta method on Mathematica by Waltraud Rufeger at the Georgia Institute of Technology.

Software

Some available software is listed here.

General Packages

General software packages include Maple, Mathematica, and Matlab. All contain algorithms for handling a large variety of both numerical and symbolic computations.

Special Packages for Linear Systems

In the IMSL Library, there are three complementary linear system packages of note.

LINPACK is a collection of programs concerned with *direct* methods for general (or full) symmetric, symmetric positive definite, triangular, and tridiagonal matrices. There are also programs for least squares problems, along with the QR algorithm for eigensystems and the singular value decompositions of rectangular matrices. The programs are intended to be completely machine independent, fully portable, and run with good efficiency in most computing environments. The LINPACK User's Guide by Dongarra *et al.* is the basic reference.

ITPACK is a modular set of programs for iterative methods. The package is oriented toward the sparse matrices that arise in the solution of PDEs and other applications. While the programs apply to full matrices, that is rarely profitable. Four basic iteration methods and two convergence acceleration methods are in the package. There is a Jacobi, SOR (with optimum relaxation parameter estimated), symmetric SOR, and reduced system (red-black ordering) iteration, each with semi-iteration and conjugate gradient acceleration. All parameters for these iterations are automatically estimated. The practical and theoretical background for ITPACK is found in Hagemen and Young (1981).

YALEPACK is a substantial collection of programs for sparse matrix computations.

Ordinary Differential Equations Packages

Also in IMSL, one finds such sophisticated software as DVERK, DGEAR, or DREBS for initial value problems. For two-point boundary value problems, one finds DTPTB (use of DVERK and multiple shooting) or DVCPR.

Partial Differential Equations Packages

DISPL was developed and written at Argonne National Laboratory. DISPL is designed for nonlinear second-order PDEs (parabolic, elliptic, hyperbolic (some cases), and parabolic-elliptic). Boundary conditions of a general nature and material interfaces are allowed. The spatial dimension can be either one or two and in Cartesian, cylindrical, or spherical (one dimension only) geometry. The PDEs are reduced to ordinary DEs by Galerkin discretization of the spatial variables. The resulting ordinary DEs in the timelike variable are then solved by an ODE software package (such as GEAR). Software features include graphics capabilities, printed output, dump/restart/facilities, and free format input. DISPL is intended to be an engineering and scientific tool and is not a finely tuned production code for a small set of problems. DISPL makes no effort to control the spatial discretization errors. It has been used to successfully solve a variety of problems in chemical transport, heat and mass transfer, pipe flow, etc.

PDELIB was developed and written at Los Alamos Scientific Laboratory. PDELIB is a library of subroutines to support the numerical solution of evolution equations with a timelike variable and one or two space variables. The routines are grouped into a dozen independent modules according to their function (i.e., accepting initial data, approximating spatial derivatives, advancing the solution in time). Each task is isolated in a distinct module. Within a module, the basic task is further refined into general-purpose flexible lower-level routines. PDELIB can be understood and used at different levels. Within a small period of time, a large class of problems can be solved by a novice. Moreover, it can provide a wide variety of outputs.

DSS/2 is a differential systems simulator developed at Lehigh University as a transportable numerical method of lines (NMOL) code. See also LEANS.

FORSIM is designed for the automated solution of sets of implicitly coupled PDEs of the form

$$\frac{\partial u_i}{\partial t} = \phi_i\left(x, t, u_i, u_j, \ldots, \left(u_i\right)_x, \ldots, \left(u_i\right)_{xx}, \left(u_j\right)_{xx}, \ldots\right), \quad \text{for } i = 1, \ldots, N$$

The user specifies the ϕ_i in a simple FORTRAN subroutine. Finite difference formulas of any order may be selected for the spatial discretization and the spatial grid need not be equidistant. The resulting system of time-dependent ODEs is solved by the method of lines.

SLDGL is a program package for the self-adaptive solution of nonlinear systems of elliptic and parabolic PDEs in up to three space dimensions. Variable step size and variable order are permitted. The discretization error is estimated and used for the determination of the optimum grid and optimum orders. This is the most general of the codes described here (not for hyperbolic systems, of course). This package has seen extensive use in Europe.

FIDISOL (finite difference solver) is a program package for nonlinear systems of two-or three-dimensional elliptic and parabolic systems in rectangular domains or in domains that can be transformed analytically to rectangular domains. This package is actually a redesign of parts of SLDGL, primarily for the solution of large problems on vector computers. It has been tested on the CYBER 205, CRAY-IM, CRAY X-MP/22, and VP 200. The program vectorizes very well and uses the vector arithmetic efficiently. In addition to the numerical solution, a reliable error estimate is computed.

CAVE is a program package for conduction analysis via eigenvalues for three-dimensional geometries using the method of lines. In many problems, much time is saved because only a few terms suffice.

Many industrial and university computing services subscribe to the IMSL Software Library. Announcements of new software appear in *Directions*, a publication of IMSL. A brief description of some IMSL packages applicable to PDEs and associated problems is now given. In addition to those packages just described, two additional software packages bear mention. The first of these, the ELLPACK system, solves elliptic problems in two dimensions with general domains and in three dimensions with box-shaped domains. The system contains over 30 numerical methods modules, thereby providing a means of evaluating and comparing different methods for solving elliptic problems. ELLPACK has a special high-level language making it easy to use. New algorithms can be added or deleted from the system with ease.

Second, TWODEPEP is IMSL's general finite element system for two-dimensional elliptic, parabolic, and eigenvalue problems. The Galerkin finite elements available are triangles with quadratic, cubic, or quartic basic functions, with one edge curved when adjacent to a curved boundary, according to the isoparametric method. Nonlinear equatons are solved by Newton's method, with the resulting linear system solved directly by Gauss elimination. PDE/PROTRAN is also available. It uses triangular elements with piecewise polynomials of degree 2, 3, or 4 to solve quite general steady state, time-dependent, and eigenvalue problems in general two-dimensional regions. There is a simple user input. Additional information may be obtained from IMSL. NASTRAN and STRUDL are two advanced finite element computer systems available from a variety of sources. Another, UNAFEM, has been extensively used.

19.13 Experimental Uncertainty Analysis

W.G. Steele and H.W. Coleman

Introduction

The goal of an experiment is to answer a question by measuring a specific variable, X_i, or by determining a result, r, from a functional relationship among J measured variables

$$r = r\left(X_1, X_2, \ldots, X_i, \ldots, X_J\right) \tag{19.13.1}$$

In all experiments there is some error that prevents the measurement of the true value of each variable, and therefore, prevents the determination of r_{true}.

Uncertainty analysis is a technique that is used to estimate the interval about a measured variable or a determined result within which the true value is thought to lie with a certain degree of confidence. As discussed in detail by Coleman and Steele (1999), uncertainty analysis is an extremely useful tool for all phases of an experimental program, from initial planning (general uncertainty analysis) to detailed design, debugging, test operation, and data analysis (detailed uncertainty analysis).

Uncertainty analysis is also beginning to be applied in the design process and in the broad area of modeling and simulation. The outcome of a design process is influenced by uncertainties inherent in input information and in the chosen process itself. The degree of accuracy of a simulation (of a flow field around an airplane, for example) is investigated by comparing the simulation output with experimental data in a process called "verification and validation." Such a comparison is obviously influenced by uncertainties in experimental data, in the numerical solution of the equations, and due to the modeling as discussed by Coleman (2003).

The international standard for uncertainty analysis is the International Organization for Standardization (ISO) *Guide to the Expression of Uncertainty in Measurement* (1995). Engineering standards that are consistent with the ISO *Guide* are available from the American Society of Mechanical Engineers (ANSI/ASME PTC 19.1-1998, 1998), the American Institute of Aeronautics and Astronautics (AIAA Standard S-071A-1999, 1999), and the Society of Automotive Engineers (SAE AIR 1678 Rev. A, 2000). These documents present and discuss the assumptions necessary for a "large sample" methodology that is consistent with the ISO *Guide*, but less complex, and that is applicable to the vast majority of engineering testing, including most single-sample tests. This methodology uses the traditional engineering concepts of systematic and random uncertainties. The range of validity of this large-sample approximation has been presented by Steele et al. (1994) and by Coleman and Steele (1995), with illustrations of its use in all aspects of engineering experimentation given by Coleman and Steele (1999).

In the following, the uncertainties of individual measured variables and of determined results are discussed. We conclude this section with an overview of the use of uncertainty analysis in all phases of an experimental program.

Uncertainty of a Measured Variable

For a measured variable X, the total error is caused by both random (precision, or varying) and systematic (bias, or fixed) errors. This relationship is shown in Figure 19.13.1. The possible measurement values of the variable are scattered in a distribution (here assumed Gaussian) around the parent population mean, μ. The parent population mean differs from X_{true} by an amount called the systematic (or bias) error, β. The quantity β is the total fixed error that remains in the measurements after all calibration corrections have been made. In general, there will be several sources of systematic error, such as errors from the calibration standard and calibration process itself, errors due to interactions of the transducer with its environment, and errors from imperfect installation of the transducer. There is usually no direct way to measure these errors, so they must be estimated.

The ISO *Guide* uncertainty model uses the standard deviation of the assumed error distribution for each error source to calculate the uncertainty in the measured variable. This standard deviation quantity is called the *standard uncertainty*. The uncertainty of the measurement of a variable is obtained from the square root of the sum of the squares of the standard uncertainties for all error sources. As described later, for those error sources that are random, or varying, the standard uncertainty can be calculated from multiple measurements of the variable, but for those sources that are systematic, or that remain fixed, the standard uncertainty must be estimated by some other means.

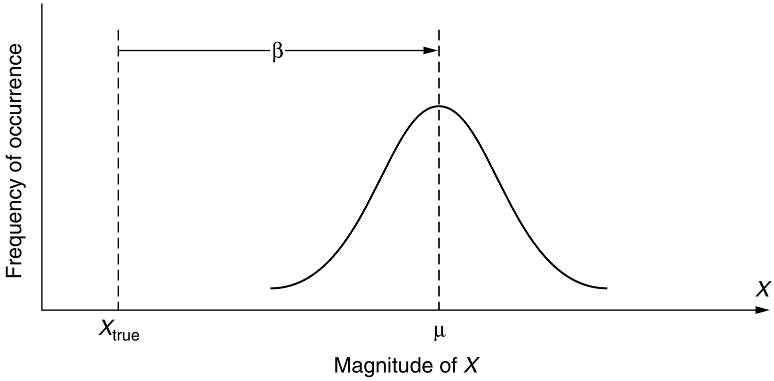

FIGURE 19.13.1 Errors in the measurement of variable X.

For each systematic error source, β_k, the experimenter must estimate a systematic standard uncertainty b_k. Systematic standard uncertainties are usually estimated from previous experience, calibration data, analytical models, and the application of sound engineering judgment.

As discussed in Coleman and Steele (1999), a useful approach for estimating a systematic uncertainty is to assume that the error for a given case is a single realization drawn from some statistical parent distribution of possible systematic errors. For example, suppose a thermistor manufacturer specifies that 95% of samples of a given model are within ±1.0°C of a reference resistance-temperature (R-T) calibration curve supplied with the thermistors. One might assume that the systematic errors (the differences between the reference curve and the actual, but unknown, R-T curves of the various thermistors) result from random processes and therefore belong to a Gaussian parent distribution with a standard deviation, or standard uncertainty, b = 0.5°C. Then the 95% confidence limits defined by ±2b = ±1.0°C would include about 95% of the possible systematic errors that could be realized from the parent distribution. For any single thermistor, this error will appear as fixed since it does not result in variation of the temperature readings when this thermistor is used to repeatedly measure a steady temperature source; however, since the magnitude of the error is unknown, a correction cannot be applied to the temperature readings, so b is used as an estimate of the systematic standard uncertainty resulting from this error.

The choice of a 95% confidence level in the previous example was made based on the thermistor manufacturer's degree of certainty in the specification of the possible interval for the fixed error in a temperature measurement. The quantity needed is the systematic standard uncertainty, b, but sometimes it is difficult to estimate the limits of the fixed error at the standard deviation level, and it is always impossible to estimate these limits at a 100% confidence level. Usually, in engineering practice, the estimate of the limits of the fixed error is made at a reasonably high confidence level, a level in the mid-90% range, or approximately 95%.

The choice of a Gaussian distribution for the possible systematic errors in the example given is generally made since most fixed errors result from some random process that is fixed for a particular experiment. Also, the well-known central-limit theorem states that errors resulting from a combination of a large number of independent sources that are equally likely to be positive or negative have distributions approaching the Gaussian distribution. Since this is usually the case for experiments, almost all experimental uncertainty analyses assume Gaussian distributions. An exception is when no information on the nature of the errors is known or assumed, and all possible error values within a range are taken to be equally probable. In this case a rectangular distribution is used. Obtaining the systematic standard uncertainty from the 95% estimate is simply a matter of dividing the estimate by the appropriate distribution factor (i.e., 2.0 for Gaussian, 1.65 for rectangular ($\sqrt{3} \times 0.95$)).

For each variable, X_i, in the data reduction equation (Equation 19.13.1), there will be a set, K_i, of elemental systematic standard uncertainties b_{i_k} for the significant fixed-error sources. The systematic standard uncertainty for variable X_i is then determined from the systematic standard uncertainty estimates for the K_i elemental error sources for that variable as

$$b_i^2 = \sum_{k=1}^{K_i} b_{i_k}^2 \tag{19.13.2}$$

An estimate of the range of random errors for measurements of a variable is the sample standard deviation, also called the random standard uncertainty. Unlike the systematic error, the random error varies from measurement to measurement. As the number of measurements, N, of a particular variable tends to infinity, the distribution of these measurements becomes Gaussian.

To reflect the entire range of possible measured values of a variable, the measurements used to calculate the random standard uncertainty must be taken over the time frame and conditions that cover the variations in the variable. For example, taking multiple samples of data as a function of time while holding all other conditions constant will identify the random variation associated with the measurement system and the unsteadiness of the test condition. If the random standard uncertainty of the variable being measured is also expected to be representative of other possible variations in the measurement (repeatability of test conditions for example), then these additional error sources will have to be varied while the multiple data samples are taken to determine the standard uncertainty.

When the value of a variable is determined as the mean, $\overline{X}$, of N readings, then the random standard uncertainty is

$$s_{\overline{X}} = \frac{1}{\sqrt{N}}\left[\frac{1}{(N-1)}\sum_{k=1}^{N}\left(X_k - \overline{X}\right)^2\right]^{\frac{1}{2}} \tag{19.13.3}$$

where

$$\overline{X} = \frac{\sum_{k=1}^{N} X_k}{N} \tag{19.13.4}$$

It must be stressed that these N measurements have to be taken over the appropriate range of variations for X as described earlier.

When only a single measurement of a variable is available in the current test so that the value used for the variable is X, then N_P previous readings, X_{P_k}, must be used to find the random standard uncertainty for the variable as

$$s_X = \left[\frac{1}{\left(N_P - 1\right)}\sum_{k=1}^{N_P}\left(X_{P_k} - \overline{X}_P\right)^2\right]^{\frac{1}{2}} \tag{19.13.5}$$

where

$$\overline{X}_P = \frac{1}{N_P}\sum_{k=1}^{N_P} X_{P_k} \tag{19.13.6}$$

If previous information is available that has an effective random standard uncertainty that is representative of what could have been observed if multiple measurements had been made, then this random standard uncertainty as determined from Equation 19.13.5 is the best estimate of the uncertainty associated with the potential variability for the single measurement.

Another situation where previous measurements of a variable are useful is when a small current sample size, N, is used to calculate the mean value, $\overline{X}$, of a variable. If a much larger set of previous measurements for the same test condition is available, then that set can be used to calculate a more appropriate random standard uncertainty for the variable (Steele et al. 1993) as

$$s_{\overline{X}} = \frac{s_X}{\sqrt{N}} \tag{19.13.7}$$

where N is the number of current measurements averaged to determine $\overline{X}$, and s_X is computed from N_P previous measurements using Equation 19.13.5. Typically, these larger data sets are taken in the early "shake-down" or "debugging" phases of an experimental program.

For many engineering applications, the large-sample approximation applies, and the 95% confidence estimate of the uncertainty for variable i (X_i or $\overline{X}_i$) is

$$U_i = 2\sqrt{b_i^2 + s_i^2} \tag{19.13.8}$$

where s_i is found from the applicable Equation 19.13.3, Equation 19.13.5, or Equation 19.13.7. The factor 2 expands the combined systematic and random standard uncertainties to obtain the 95% confidence limits for the uncertainty U_i. The interval $X_i \pm U_i$ or $\overline{X}_i \pm U_i$, as appropriate, should contain $X_{i_{\text{true}}}$ 95 times out of 100.

Uncertainty of a Result

Consider an experimental result that is determined from J measured variables as

$$r = r\left(X_1, X_2, \ldots, X_i, \ldots, X_J\right) \tag{19.13.9}$$

where some variables may be single measured values and others may be mean values. A typical mechanical engineering experiment would be the determination of the heat transfer in a heat exchanger as

$$q = \dot{m} c_p \left(T_o - T_i\right) \tag{19.13.10}$$

where q is the heat rate, $\dot{m}$ is the flow rate, c_p is the fluid specific heat, and T_o and T_i are the heated fluid outlet and inlet temperatures, respectively. For the large-sample approximation, U_r is found as

$$U_r = 2\sqrt{b_r^2 + s_r^2} \tag{19.13.11}$$

where b_r is the systematic standard uncertainty of the result

$$b_r^2 = \sum_{i=1}^{J} (\theta_i b_i)^2 + 2 \sum_{i=1}^{J-1} \sum_{k=i+1}^{J} \theta_i \theta_k b_{ik} \tag{19.13.12}$$

with

$$\theta_i = \frac{\partial r}{\partial X_i} \tag{19.13.13}$$

and s_r is the random standard uncertainty of the result

$$s_r^2 = \sum_{i=1}^{J} \left(\theta_i s_i\right)^2 \tag{19.13.14}$$

The term b_{ik} in Equation 19.13.12 is the covariance of the systematic standard uncertainties. When the elemental systematic standard uncertainties for two separately measured variables are related, for instance when the transducers used to measure different variables are each calibrated against the same standard, the systematic standard uncertainties are said to be correlated and the covariance of the systematic errors is nonzero. The significance of correlated systematic standard uncertainties is that they can have the effect of either decreasing or increasing the uncertainty in the result. The covariance term, b_{ik}, is determined by summing the products of the elemental systematic standard uncertainties for variables i and k that arise from the same source and are therefore perfectly correlated (Brown et al. 1996) as

$$b_{ik} = \sum_{\alpha=1}^{L} b_{i_\alpha} b_{k_\alpha} \tag{19.13.15}$$

where L is the number of elemental systematic error sources that are common for measurements X_i and X_k.

If, for example,

$$r = r\left(X_1, X_2\right) \tag{19.13.16}$$

and it is possible for portions of the systematic standard uncertainties b_1 and b_2 to arise from the same source(s), then Equation 19.13.12 gives

$$b_r^2 = \theta_1^2 b_1^2 + \theta_2^2 b_2^2 + 2\theta_1 \theta_2 b_{12} \tag{19.13.17}$$

For a case in which the measurements of X_1 and X_2 are each influenced by four elemental systematic error sources and sources 2 and 3 are the same for both X_1 and X_2, Equation 19.13.2 gives

$$b_1^2 = b_{1_1}^2 + b_{1_2}^2 + b_{1_3}^2 + b_{1_4}^2 \tag{19.13.18}$$

and

$$b_2^2 = b_{2_1}^2 + b_{2_2}^2 + b_{2_3}^2 + b_{2_4}^2 \tag{19.13.19}$$

while Equation 19.13.15 gives

$$b_{12} = b_{1_2} b_{2_2} + b_{1_3} b_{2_3} \tag{19.13.20}$$

In the general case, there would be additional terms in the expression for the random standard uncertainty of the result, s_r, (Equation 19.13.14) to take into account the possibility of random errors in different variables being correlated. These terms have traditionally been neglected, although random errors in different variables caused by the same uncontrolled factor(s) are certainly possible and can have a substantial impact on the value of s_r (Hudson et al. 1996). In such cases, one would need to acquire sufficient data to allow a valid estimate of the random covariance terms using standard statistical techniques (ISO, 1995). Note, however, that if multiple test results over an appropriate time period are available, these can be used (as described earlier) to directly determine s_r. This value of the random standard uncertainty of the result implicitly includes the correlated error effect.

If a test is performed so that M multiple sets of measurements (X_{1_k}, X_{2_k}, …, X_{J_k}) at the same test condition are obtained, then M results can be determined using Equation 19.13.1 and the mean result, $\bar{r}$, can be determined using

$$\bar{r} = \frac{1}{M} \sum_{k=1}^{M} r_k \tag{19.13.21}$$

The random standard uncertainty of the sample of M results, s_r, is calculated as

$$s_r = \left[\frac{1}{\left(M-1\right)} \sum_{k=1}^{M} \left(r_k - \bar{r}\right)^2 \right]^{\frac{1}{2}} \tag{19.13.22}$$

The uncertainty associated with the mean result, $\bar{r}$, for the "large sample" approximation is then

$$U_{\bar{r}} = 2\sqrt{b_r^2 + s_{\bar{r}}^2} \tag{19.13.23}$$

where

$$s_{\bar{r}} = \frac{s_r}{\sqrt{M}} \tag{19.13.24}$$

and where b_r is given by Equation 19.13.12.

The large sample approximation for the uncertainty of a determined result (Equation 19.13.11 or Equation 19.13.23) applies for most engineering applications even when some of the variables have small numbers of samples. A detailed discussion of the applicability of this approximation is given in Steele et al. (1994) and Coleman and Steele (1995).

The determination of U_r from s_r (or $s_{\bar{r}}$) and b_r using the large-sample approximation is called detailed uncertainty analysis (Coleman and Steele, 1999). The interval $r \pm U_r$ (or $\bar{r} \pm U_{\bar{r}}$) should contain r_{true} 95 times out of 100. As discussed in the next section, detailed uncertainty analysis is an extremely useful tool in an experimental program. However, in the early stages of the program, it is useful to simply estimate the overall uncertainty for each variable, U_i. The overall uncertainty of the result is then determined as

$$U_r^2 = \sum_{i=1}^{J} \left(\theta_i U_i\right)^2 \tag{19.13.25}$$

This determination of U_r is called general uncertainty analysis.

Using Uncertainty Analysis in Experimentation

The first item that should be considered in any experimental program is "What question are we trying to answer?" Another key item is how accurately do we need to know the answer, or what "degree of goodness" is required? With these two items specified, general uncertainty analysis can be used in the planning phase of an experiment to evaluate the possible uncertainties from the various approaches that might be used to answer the question being addressed. Critical measurements that will contribute most to the uncertainty of the result can also be identified.

Once past the planning, or preliminary design, phase of the experiment, the effects of systematic errors and random errors are considered separately using the techniques of detailed uncertainty analysis. In the design phase of the experiment, estimates are made of the systematic and random standard uncertainties, b_r and s_r, and the uncertainty, U_r, expected in the experimental result. These detailed design considerations guide the decisions made during the construction phase of the experiment.

After the test is constructed, a debugging phase is required before production tests are begun. In the debugging phase, multiple tests are run and the random standard uncertainty determined from them is compared with the s_r value estimated in the design phase. Also, a check is made to see if the test results plus and minus U_r compare favorably with known results for certain ranges of operation. If these checks are not successful, then further test design, construction, and debugging is required.

Once the test operation is fully understood, then the execution phase can begin. In this phase, balance checks can be used to monitor the operation of the test apparatus. In a balance check, a quantity, such as flow rate, is determined by different means and the difference in the two determinations, z, is compared to the ideal value of zero. For the balance check to be satisfied, the quantity z must be less than or equal to U_z.

Uncertainty analysis will of course play a key role in the data analysis and reporting phases of an experiment. When an experimental result is reported, the uncertainty should be given along with the associated confidence level, usually 95%. Also, the values and details of the determination of the systematic standard uncertainty, b_r, and the random standard uncertainty, s_r, should be included. When a range of test results is presented as a regression equation, then a statement must be made of the uncertainty of the values obtained from the equation. This topic is discussed in detail in Brown et al. (1998) and in Coleman and Steele (1999).

19.14 Chaos

R. L. Kautz

Introduction

Since the time of Newton, the science of dynamics has provided quantitative descriptions of regular motion, from a pendulum's swing to a planet's orbit, expressed in terms of differential equations. However, the role of Newtonian mechanics has recently expanded with the realization that it can also describe chaotic motion. In elementary terms, **chaos** can be defined as **pseudorandom** behavior observed in the steady-state dynamics of a deterministic **nonlinear system**. How can motion be pseudorandom, or random according to statistical tests, and yet be entirely predictable? This is just one of the paradoxes of chaotic motion, which is globally stable but locally unstable, predictable in principle but not in practice, and geometrically complex but derived from simple equations.

The strange nature of chaotic motion was first understood by Henri Poincaré, who established the mathematical foundations of chaos in a treatise published in 1890 [Holmes, 1990]. However, the practical importance of chaos began to be widely appreciated only in the 1960's, beginning with the work of Edward Lorenz [1963], a meteorologist who discovered chaos in a simple model for fluid convection. Today, chaos is understood to explain a wide variety of apparently random natural phenomena, ranging from dripping faucets [Martien, 1985] to the flutter of a falling leaf [Tanabe, 1994] to the irregular rotation of a moon of Saturn [Wisdom, 1984].

Although chaos is used purposely to provide an element of unpredictability in some toys and carnival rides [Kautz, 1994], it is important from an engineering point of view primarily as a phenomenon to be avoided. Perhaps the simplest scenario arises when a nonlinear mechanism is used to achieve a desired effect, such as the synchronization of two oscillators. In many such cases, the degree of nonlinearity must be chosen carefully: strong enough to ensure the desired effect but not so strong that chaos results. In another scenario, an engineer might be required to deal with an intrinsically chaotic system. In this case, if the system can be modeled mathematically, then a small feedback signal can often be applied to eliminate the chaos [Ott, 1990]. For example, low-energy feedback has been used to suppress chaotic behavior in a thermal convection loop [Singer, 1991]. As such considerations suggest, chaos is rapidly becoming an important topic for engineers.

Flows, Attractors, and Liapunov Exponents

Dynamical systems can generally be described mathematically in terms of a set of differential equations of the form

$$d\mathbf{x}(t)/dt = \mathbf{F}\left[\mathbf{x}(t)\right], \tag{19.14.1}$$

where $\mathbf{x} = (x_1, \ldots, x_N)$ is an N-dimensional vector called the **state vector** and the vector function $\mathbf{F} = (F_1(\mathbf{x}), \ldots, F_N(\mathbf{x}))$ defines how the state vector changes with time. In mechanics, the state variables x_i are typically the positions and velocities associated with the potential and kinetic energies of the system. Because the state vector at times $t > 0$ depends only on the initial state vector $\mathbf{x}(0)$, the system defined by Equation (19.14.1) is deterministic, and its motion is in principle exactly predictable.

The properties of a dynamical system are often visualized most readily in terms of trajectories $\mathbf{x}(t)$ plotted in **state space**, where points are defined by the coordinates $(x_1, \ldots, x_N)$. As an example, consider the motion of a damped pendulum defined by the normalized equation

$$d^2\theta/dt^2 = -\sin\theta - \rho d\theta/dt, \tag{19.14.2}$$

which expresses the angular acceleration $d^2\theta/dt^2$ in terms of the gravitational torque $-\sin\theta$ and a damping torque $-\rho d\theta/dt$ proportional to the angular velocity $v = d\theta/dt$. If we define the state vector as $\mathbf{x} = (x_1, x_2) = (\theta, v)$, then Equation (19.14.2) can be written in the form of Equation (19.14.1) with $\mathbf{F} = (x_2, -\sin x_1 - \rho x_2)$. In this case, the state space is two dimensional, and a typical trajectory is a spiral, as shown in Figure 19.14.1 for the initial condition $\mathbf{x}(0) = (0, 1)$. If additional trajectories, corresponding to other initial conditions, were plotted in Figure 19.14.1, we would obtain a set of interleaved spirals, all converging on the point $\mathbf{x} = (0, 0)$. Because the direction of a trajectory passing through a given point is uniquely defined by Equation (19.14.1), state-space trajectories can never cross, and, by analogy with the motion of a fluid, the set of all of trajectories is called a flow.

The tendency of a flow to converge toward a single point or other restricted subset of state space is characteristic of dissipative systems like the damped pendulum. Such an asymptotic set, called an attracting set or **attractor**, can be a fixed point (for which $\mathbf{F}(\mathbf{x}) = 0$) as in Figure 19.14.1, but might also be a periodic or chaotic trajectory. The convergence of neighboring trajectories is suggested in Figure 19.14.1 by a series of ellipses spaced at time intervals $\Delta t = 1.5$ that track the flow of all trajectories originating within the circle specified at $t = 0$. In general, the contraction of an infinitesimal state-space volume V as it moves with the flow is given by

$$V^{-1}\partial V/\partial t = \nabla \cdot \mathbf{F}, \tag{19.14.2}$$

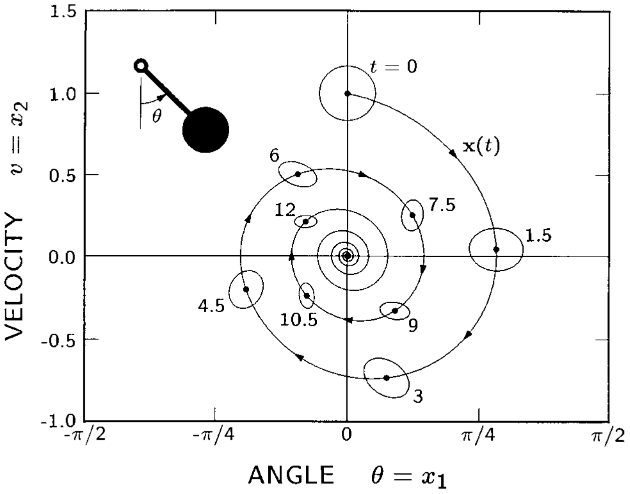

FIGURE 19.14.1 The state-space trajectory $\mathbf{x}(t)$ for a pendulum with a damping coefficient $\rho = 0.2$ for the initial condition $\mathbf{x}(0) = (0, 1)$. The evolution of trajectories initialized in a small circle surrounding $\mathbf{x} = (0, 1)$ is indicated by the ellipses plotted at time intervals of $\Delta t = 1.5$.

where $\nabla \cdot \mathbf{F} = \sum_{i=1}^{N} \partial F_i/\partial x_i$ is the divergence of **F**. For the damped pendulum, $\nabla \cdot \mathbf{F} = -\rho$, so the area of the ellipse shown in Figure 19.14.1 shrinks exponentially as $V(t) = V(0)\exp(-\rho t)$. The contraction of state-space volumes explains the existence of attractors in dissipative systems, but, in conservative systems such as the pendulum with $\rho = 0$, state-space volumes are preserved, and trajectories are instead confined to constant-energy surfaces.

While the existence of chaotic behavior is generally difficult to predict, two essential conditions are easily stated. First, the complex topology of a chaotic trajectory can exist only in a state space of dimension $N \geq 3$. Thus, the pendulum defined by Equation (19.14.2) cannot be chaotic because $N = 2$ for this system. Second, a system must be nonlinear to exhibit chaotic behavior. Linear systems, for which any linear combination $c_1\mathbf{x}_a(t) + c_2\mathbf{x}_b(t)$ of two solutions $\mathbf{x}_a(t)$ and $\mathbf{x}_b(t)$ is also a solution, are mathematically simple and amenable to analysis. In contrast, nonlinear systems are noted for their intractability. Thus, chaotic behavior is of necessity explored more frequently by numerical simulation than mathematical analysis, a fact that helps explain why the prevalence of chaos was discovered only after the advent of efficient computation.

A useful criterion for the existence of chaos can be developed from an analysis of a trajectory's local stability. As sketched in Figure 19.14.2, the local stability of a trajectory $\mathbf{x}(t)$ is determined by considering

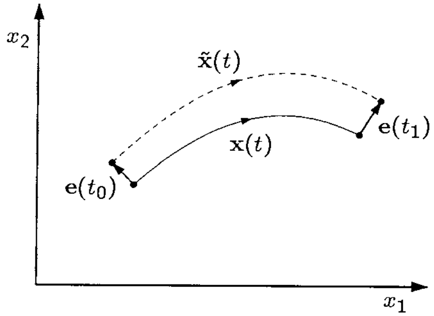

FIGURE 19.14.2 A trajectory $\mathbf{x}(t)$ and a neighboring trajectory $\tilde{\mathbf{x}}(t)$ plotted in state space from time t_0 to t_1. The vectors $\mathbf{e}(t_0)$ and $\mathbf{e}(t_1)$ indicate the deviation of $\tilde{\mathbf{x}}(t)$ from $\mathbf{x}(t)$ at times t_0 and t_1.

a neighboring trajectory $\tilde{\mathbf{x}}(t)$ initiated by an infinitesimal deviation $\mathbf{e}(t_0)$ from $\mathbf{x}(t)$ at time t_0. The deviation vector $\mathbf{e}(t)=\tilde{\mathbf{x}}(t)-\mathbf{x}(t)$ at times $t_1 > t_0$ can be expressed in terms of the Jacobian matrix

$$J_{ij}(t_1,t_0)=\partial x_i(t_1)/\partial x_j(t_0), \tag{19.14.3}$$

which measures the change in state variable x_i at time t_1 due to a change in x_j at time t_0. From the Jacobian's definition, we have $\mathbf{e}(t_1)=\mathbf{J}(t_1,t_0)\mathbf{e}(t_0)$. Although the local stability of $\mathbf{x}(t)$ is determined simply by whether deviations grow or decay in time, the analysis is complicated by the fact that deviation vectors can also rotate, as suggested in Figure 19.14.2. Fortunately, an arbitrary deviation can be written in terms of the eigenvectors $\mathbf{e}^{(i)}$ of the Jacobian, defined by

$$\mathbf{J}\left(t_1,t_0\right)\mathbf{e}^{(i)}=\mu_i\left(t_1,t_0\right)\mathbf{e}^{(i)}, \tag{19.14.4}$$

which are simply scaled by the eigenvalues $\mu_i(t_1,t_0)$ without rotation. Thus, the N eigenvalues of the Jacobian matrix provide complete information about the growth of deviations. Anticipating that the asymptotic growth will be exponential in time, we define the **Liapunov exponents**,

$$\lambda_i=\lim_{t_1\to\infty}\frac{\ln\left|\mu_i\left(t_1,t_0\right)\right|}{t_1-t_0}. \tag{19.14.5}$$

Because any deviation can be broken into components that grow or decay asymptotically as $\exp(\lambda_i t)$, the N exponents associated with a trajectory determine its local stability.

In dissipative systems, chaos can be defined as motion on an attractor for which one or more Liapunov exponents are positive. Chaotic motion thus combines global stability with local instability in that motion is confined to the attractor, generally a bounded region of state space, but small deviations grow exponentially in time. This mixture of stability and instability in chaotic motion is evident in the behavior of an infinitesimal deviation ellipsoid similar to the finite ellipse shown in Figure 19.14.1. Because some λ_i are positive, an ellipsoid centered on a chaotic trajectory will expand exponentially in some directions. On the other hand, because state-space volumes always contract in dissipative systems and the asymptotic volume of the ellipsoid scales as $\exp(\Lambda t)$, where $\Lambda=\sum_{i=1}^{N}\lambda_i$, the sum of the negative exponents must be greater in magnitude than the sum of the positive exponents. Thus, a deviation ellipsoid tracking a chaotic trajectory expands in some directions while contracting in others. However, because an arbitrary deviation almost always includes a component in a direction of expansion, nearly all trajectories neighboring a chaotic trajectory diverge exponentially.

According to our definition of chaos, neighboring trajectories must diverge exponentially and yet remain on the attractor. How is this possible? Given that the attractor is confined to a bounded region of state space, perpetual divergence can occur only for trajectories that differ infinitesimally. Finite deviations grow exponentially at first but are limited by the bounds of the chaotic attractor and eventually shrink again. The full picture can be understood by following the evolution of a small state-space volume selected in the neighborhood of the chaotic attractor. Initially, the volume expands in some directions and contracts in others. When the expansion becomes too great, however, the volume begins to fold back on itself so that trajectories initially separated by the expansion are brought close together again. As time passes, this stretching and folding is repeated over and over in a process that is often likened to kneading bread or pulling taffy.

Because all neighboring volumes approach the attractor, the stretching and folding process leads to an attracting set that is an infinitely complex filigree of interleaved surfaces. Thus, while the differential equation that defines chaotic motion can be very simple, the resulting attractor is highly complex. Chaotic attractors fall into a class of geometric objects called **fractals**, which are characterized by the presence of structure at arbitrarily small scales and by a dimension that is generally fractional. While the existence

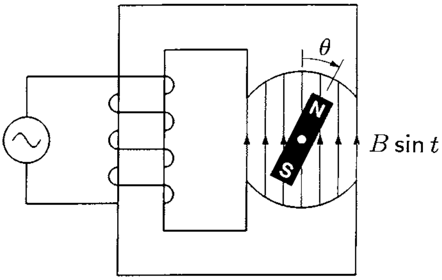

FIGURE 19.14.3 A synchronous motor, consisting of a permanent magnet free to rotate in a uniform magnetic field $B\sin t$ with an amplitude that varies sinusoidally in time.

of objects with dimensions falling between those of a point and a line, a line and a surface, or a surface and a volume may seem mysterious, fractional dimensions result when dimension is defined by how much of an object is apparent at various scales of resolution. For the dynamical systems encompassed by Equation (19.14.1), the fractal dimension D of a chaotic attractor falls in the range $2 < D < N$ where N is the dimension of the state space. Thus, the dimension of a chaotic attractor is large enough that trajectories can continually explore new territory within a bounded region of state space but small enough that the attractor occupies no volume of the space.

Synchronous Motor

As an example of a system that exhibits chaos, we consider a simple model for a synchronous motor that might be used in a clock. As shown in Figure 19.14.3, the motor consists of a permanent-magnet rotor subjected to a uniform oscillatory magnetic field $B\sin t$ provided by the stator. In dimensionless notation, its equation of motion is

$$d^2\theta/dt^2 = -f\sin t \sin\theta - \rho d\theta/dt, \tag{19.14.6}$$

where $d^2\theta/dt^2$ is the angular acceleration of the rotor, $-f\sin t\sin\theta$ is the torque due to the interaction of the rotor's magnetic moment with the stator field, and $-\rho d\theta/dt$ is a viscous damping torque. Although Equation (19.14.7) is explicitly time dependent, it can be cast in the form of Equation (19.14.1) by defining the state vector as $\mathbf{x} = (x_1, x_2, x_3) = (\theta, v, t)$, where $v = d\theta/dt$ is the angular velocity, and by defining the flow as $\mathbf{F} = (x_2, -f\sin x_3 \sin x_1 - \rho x_2, 1)$. The state space is thus three dimensional and large enough to allow chaotic motion. Equation (19.14.7) is also nonlinear due to the term $-f\sin t\sin\theta$, since $\sin(\theta_a + \theta_b)$ is not generally equal to $\sin\theta_a + \sin\theta_b$. Chaos in this system has been investigated by several authors [Ballico, 1990].

By intent, the motor uses nonlinearity to synchronize the motion of the rotor with the oscillatory stator field, so it revolves exactly once during each field oscillation. Although synchronization can occur over a range of system parameters, proper operation requires that the drive amplitude f, which measures the strength of the nonlinearity, be chosen large enough to produce the desired rotation but not so large that chaos results. Calculating the motor's dynamics for $\rho = 0.2$, we find that the rotor oscillates without rotating for f less than 0.40 and that the intended rotation is obtained for $0.40 < \rho < 1.87$. The periodic attractor corresponding to synchronized rotation is shown for $f = 1$ in Figure 19.14.4(a). Here the three-dimensional state-space trajectory is projected onto the (x_1, x_2) or (θ, v) plane, and a dot marks the point in the rotation cycle at which $t = 0$ modulo 2π. As Figure 19.14.4(a) indicates, the rotor advances by exactly 2π during each drive cycle.

The utility of the motor hinges on the stability of the synchronous rotation pattern shown in Figure 19.14.4(a). This periodic pattern is the steady-state motion that develops after initial transients decay and represents the final asymptotic trajectory resulting for initial conditions chosen from a wide area of

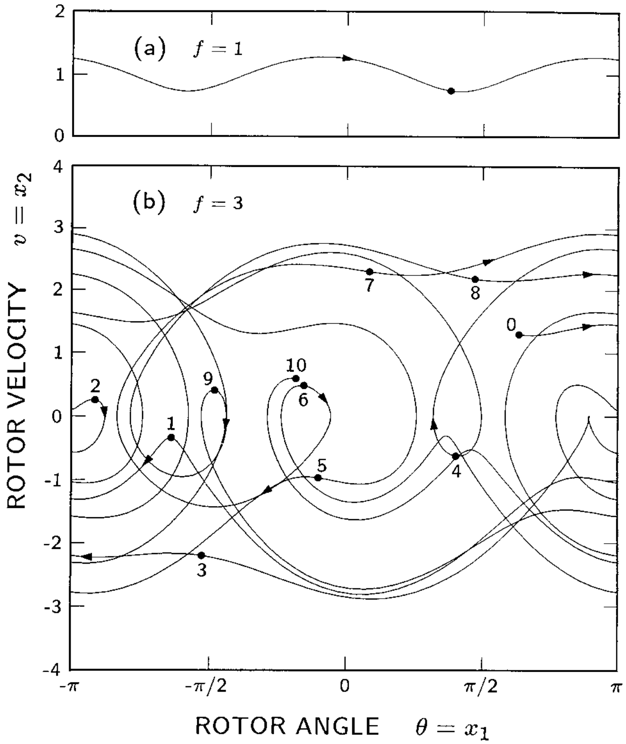

FIGURE 19.14.4 State-space trajectories projected onto the (x_1, x_2) or (θ, v) plane, showing attractors of the synchronous motor for $\rho = 0.2$ and two drive amplitudes, $f = 1$ and 3. Dots mark the state of the system at the beginning of each drive cycle ($t = 0$ modulo 2π). The angles $\theta = \pi$ and $-\pi$ are equivalent.

state space. Because the flow approaches this attracting set from all neighboring points, the effect of a perturbation that displaces the system from the attractor is short lived. This stability is reflected in the Liapunov exponents of the attractor: $\lambda_1 = 0$ and $\lambda_2 = \lambda_3 = -0.100$. The zero exponent is associated with deviations coincident with the direction of the trajectory and is a feature common to all bounded attractors other than fixed points. The zero exponent results because the system is neutrally stable with respect to offsets in the time coordinate. The exponents of -0.100 are associated with deviations transverse to the trajectory and indicate that these deviations decay exponentially with a characteristic time of 1.6 drive cycles. The negative exponents imply that the synchrony between the rotor and the field is maintained in spite of noise or small variations in system parameters, as required of a clock motor.

For drive amplitudes greater than $f = 1.87$, the rotor generally does not advance by precisely 2π during every drive cycle, and its motion is commonly chaotic. An example of chaotic behavior is illustrated for $f = 3$ by the trajectory plotted in Figure 19.14.4(b) over an interval of 10 drive cycles. In this figure, sequentially numbered dots mark the beginning of each drive cycle. When considered cycle by cycle, the trajectory proves to be a haphazard sequence of oscillations, forward rotations, and reverse rotations. Although we might suppose that this motion is just an initial transient, it is instead characteristic of the steady-state behavior of the motor. If extended, the trajectory continues with an apparently random mixture of oscillation and rotation, without approaching a repetitive cycle. The motion is aptly described as chaotic.

The geometry of the chaotic attractor sampled in Figure 19.14.4(b) is revealed more fully in Figure 19.14.5. Here we plot points (θ, v) recording the instantaneous angle and velocity of the rotor at the beginning of each drive cycle for 100,000 successive cycles. Called a **Poincaré section**, Figure 19.14.5 displays the three-dimensional attractor as its intersection with the planes $t = x_3 = 0$ modulo 2π, corresponding to equivalent times in the drive cycle. For the periodic attractor of Figure 19.14.4(a), the rotor

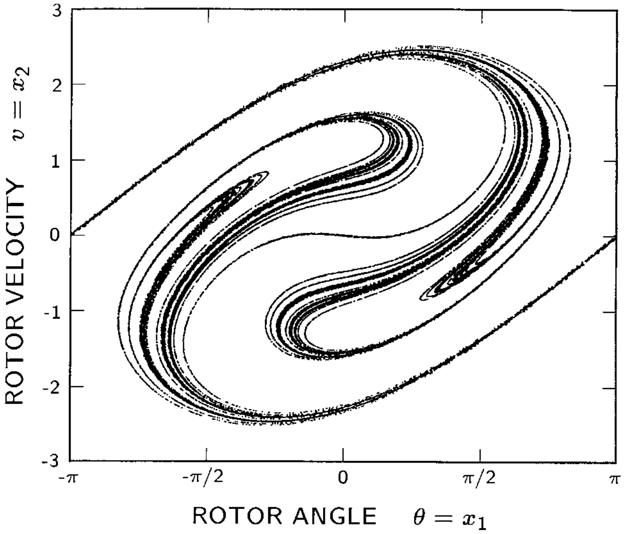

FIGURE 19.14.5 Poincaré section of a chaotic attractor of the synchronous motor with $\rho = 0.2$ and $f = 3$, obtained by plotting points $(x_1,x_2) = (\theta,v)$ corresponding to the position and velocity of the rotor at the beginning of 100,000 successive drive cycles.

returns to the same position and velocity at the beginning of each drive cycle, so its Poincaré section is a single point, the dot in this figure. For chaotic motion, in contrast, we obtain the complex swirl of points shown in Figure 19.14.5. If the system is initialized at a point far from the swirl, the motion quickly converges to this attracting set. On succeeding drive cycles, the state of the system jumps from one part of the swirl to another in an apparently random fashion that continues indefinitely. As the number of plotted points approaches infinity, the swirl becomes a cross section of the chaotic attractor. Thus, Figure 19.14.5 approximates a slice through the infinite filigree of interleaved surfaces that compose the attracting set. In this case, the fractal dimension of the attractor is 2.52 and that of its Poincaré section is 1.52.

The computed Liapunov exponents of the chaotic solution at $\rho = 0.2$ and $f = 3$ are $\lambda_1 = 0$, $\lambda_2 = 0.213$, and $\lambda_3 = -0.413$. As for the periodic solution, the zero exponent implies neutral stability associated with deviations directed along a given trajectory. The positive exponent, which signifies the presence of chaos, is associated with deviations transverse to the given trajectory but tangent to the surface of the attracting set in which it is embedded. The positive exponent implies that such deviations grow exponentially in time and that neighboring trajectories on the chaotic attractor diverge exponentially, a property characteristic of chaotic motion. The negative exponent is associated with deviations transverse to the surface of the attractor and assures the exponential decay of displacements from the attracting set. Thus, the Liapunov exponents reflect both the stability of the chaotic attractor and the instability of a given chaotic trajectory with respect to neighboring trajectories.

One consequence of a positive Liapunov exponent is a practical limitation on our ability to predict the future state of a chaotic system. This limitation is illustrated in Figure 19.14.6, where we plot a given chaotic trajectory (solid line) and three perturbed trajectories (dashed lines) that result by offsetting the initial phase of the given solution by various deviations $e_1(0)$. When the initial angular offset is $e_1(0)=10^{-3}$ radian, the perturbed trajectory (short dash) closely tracks the given trajectory for about 7 drive cycles before the deviation become significant. After 7 drive cycles, the perturbed trajectory is virtually independent of the given trajectory, even though it is confined to the same attractor. Similarly, initial offsets of 10^{-6} and 10^{-9} radian lead to perturbed trajectories (medium and long dash) that track the given trajectory for about 12 and 17 drive cycles, respectively, before deviations become significant. These results reflect the fact that small deviations grow exponentially and, in the present case, increase on average by a factor of 10 every 1.7 drive cycles. If the position of the rotor is to be predicted with an

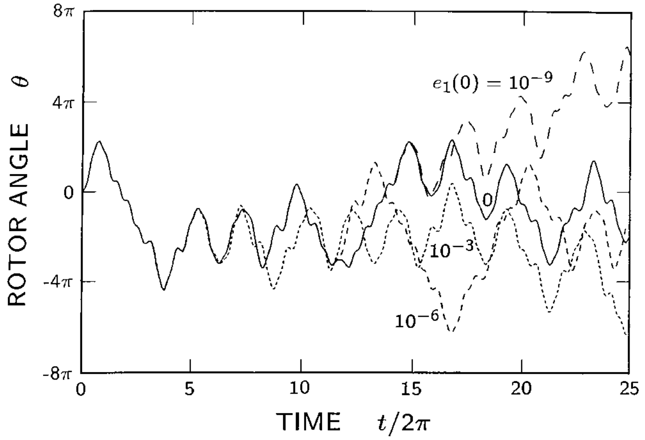

FIGURE 19.14.6 Rotor angle as a function of time for chaotic trajectories of the synchronous motor with ρ = 0.2 and $f = 3$. Solid line shows a given trajectory and dashed lines show perturbed trajectories resulting from initial angular deviations of $e_1(0)=10^{-3}$ (short dash), 10^{-6} (medium dash), and 10^{-9} (long dash).

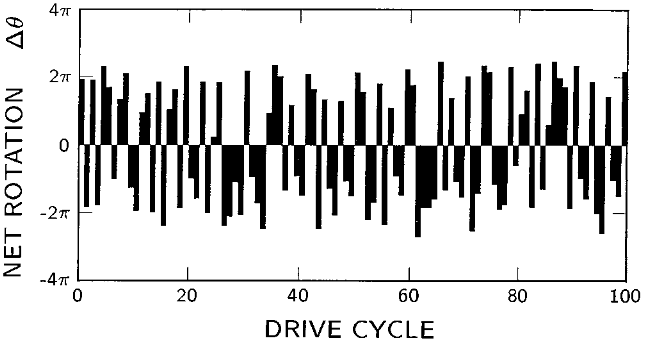

FIGURE 19.14.7 Net rotation of a synchronous motor during each of 100 successive drive cycles, illustrating chaotic motion for ρ = 0.2 and $f = 3$. By definition, $\Delta\theta = \theta(2\pi n) - \theta(2\pi(n-1))$ on the nth drive cycle.

accuracy of 10^{-1} radian after 20 drive cycles, its initial angle must be known to better than 10^{-13} radian and the calculation must be carried out with at least 14 significant digits. If a similar prediction is to be made over 40 drive cycles, then 25 significant digits are required. Thus, even though chaotic motion is predictable in principle, the state of a chaotic system can be accurately predicted in practice for only a short time into the future. According to Lorenz [1993], this effect explains why weather forecasts are of limited significance beyond a few days.

The pseudorandom nature of chaotic motion is illustrated in Figure 19.14.7 for the synchronous motor by a plot of the net rotation during each of 100 successive drive cycles. Although this sequence of rotations results from solving a deterministic equation, it is apparently random, jumping erratically between forward and reverse rotations of various magnitudes up to about 1.3 revolutions. The situation is similar to that of a digital random number generator, in which a deterministic algorithm is used to produce a sequence of pseudorandom numbers. In fact, the similarity is not coincidental since chaotic processes often underlie such algorithms [Li, 1978]. For the synchronous motor, statistical analysis reveals almost no correlation between rotations separated by more than a few drive cycles. This statistical independence is a result of the motor's positive Liapunov exponent. Because neighboring trajectories diverge exponentially, a small region of the attractor can quickly expand to cover the entire attractor, and a small range of rotations on one drive cycle can lead to almost any possible rotation a few cycles later. Thus, there is little correlation between rotations separated by a few drive cycles, and on this time scale the motor appears to select randomly between the possible rotations.

From an engineering point of view, the problem of chaotic behavior in the synchronous motor can be solved simply by selecting a drive amplitude in the range $0.40 < f < 1.87$. Within this range, the strength of the nonlinearity is large enough to produce synchronization but not so large as to produce chaos. As this example suggests, it is important to recognize that erratic, apparently random motion can be an intrinsic property of a dynamical system and is not necessarily a product of external noise. Searching a real motor for a source of noise to explain the behavior shown in Figure 19.14.7 would be wasted effort since the cause is hidden in a noise-free differential equation. Clearly, chaotic motion is a possibility that every engineer should understand.

Defining Terms

Attractor: A set of points in state space to which neighboring trajectories converge in the limit of large time.

Chaos: Pseudorandom behavior observed in the steady-state dynamics of a deterministic nonlinear system.

Fractal: A geometric object characterized by the presence of structure at arbitrarily small scales and by a dimension that is generally fractional.

Liapunov exponent: One of N constants λ_i that characterize the asymptotic exponential growth of infinitesimal deviations from a trajectory in an N-dimensional state space. Various components of a deviation grow or decay on average in proportion to $\exp(\lambda_i t)$.

Nonlinear system: A system of equations for which a linear combination of two solutions is not generally a solution.

Poincaré section: A cross section of a state-space trajectory formed by the intersection of the trajectory with a plane defined by a specified value of one state variable.

Pseudorandom: Random according to statistical tests but derived from a deterministic process.

State space: The space spanned by state vectors.

State vector: A vector $\mathbf{x}$ whose components are the variables, generally positions and velocities, that define the time evolution of a dynamical system through an equation of the form $d\mathbf{x}/dt = \mathbf{F}(\mathbf{x})$, where $\mathbf{F}$ is a vector function.

Further Information

A practical introduction to deterministic chaos for undergraduates is provided by *Chaotic and Fractal Dynamics: An Introduction for Applied Scientists and Engineers* by Francis C. Moon. This book emphasizes an experimental point of view, presenting numerous examples drawn from mechanical and electrical engineering.

While written at an undergraduate level, *Chaos: An Introduction to Dynamical Systems* by Kathleen T. Alligood, Tim D. Sauer, and James A. York probes deeply into the mathematical foundations of chaos.

Chaos in Dynamical Systems by Edward Ott gives a rigorous introduction to chaotic dynamics at the graduate level.

Practical methods for experimental analysis and control of chaotic systems are presented in *Coping with Chaos: Analysis of Chaotic Data and the Exploitation of Chaotic Systems*, a reprint volume edited by Edward Ott, Tim Sauer, and James A. York.

19.15 Fuzzy Sets and Fuzzy Logic

Dan M. Frangopol

Introduction

In the sixties, Zaheh (1965) introduced the concept of fuzzy sets. Since its inception more than 30 years ago, the theory and methods of fuzzy sets have developed considerably. The demands for treating situations in engineering, social sciences, and medicine, among other applications that are complex and not crisp have been strong driving forces behind these developments.

The concept of the fuzzy set is a generalization of the concept of the ordinary (or crisp) set. It introduces vagueness by eliminating the clear boundary, defined by the ordinary set theory, between full nonmembers (i.e., grade of membership equals zero) and full members (i.e., grade of membership equals one). According to Zaheh (1965) a fuzzy set A, defined as a collection of elements (also called objects) $x \in X$, where X denotes the universal set (also called universe of discourse) and the symbol $\in$ denotes that the element x is a member of X, is characterized by a membership (also called characteristic) function $\mu_A(x)$ which associates each point in X a real member in the unit interval [0,1]. The value of $\mu_A(x)$ at x represents the grade of membership of x in A. Larger values of $\mu_A(x)$ denote higher grades of membership of x in A. For example, a fuzzy set representing the concept of control might assign a degree of membership of 0.0 for no control, 0.1 for weak control, 0.5 for moderate control, 0.9 for strong control, and 1.0 for full control. From this example, it is clear that the two-valued crisp set [i.e., no control (grade of membership 0.0) and full control (grade of membership 1.0)] is a particular case of the general multivalued fuzzy set A in which $\mu_A(x)$ takes its values in the interval [0,1].

Problems in engineering could be very complex and involve various concepts of uncertainty. The use of fuzzy sets in engineering has been quite extensive during this decade. The area of fuzzy control is one of the most developed applications of fuzzy set theory in engineering (Klir and Folger, 1988). Fuzzy controllers have been created for the control of robots, aircraft autopilots, and industrial processes, among others. In Japan, for example, so-called "fuzzy electric appliances," have gained great success from both technological and commercial points of view (Furuta, 1995). Efforts are underway to develop and introduce fuzzy sets as a technical basis for solving various real-world engineering problems in which the underlying information is complex and imprecise. In order to achieve this, a mathematical background in the theory of fuzzy sets is necessary. A brief summary of the fundamental mathematical aspects of the theory of fuzzy sets is presented herein.

Fundamental Notions

A fuzzy set A is represented by all its elements x_i and associated grades of membership $\mu_A(x_i)$ (Klir and Folger, 1988).

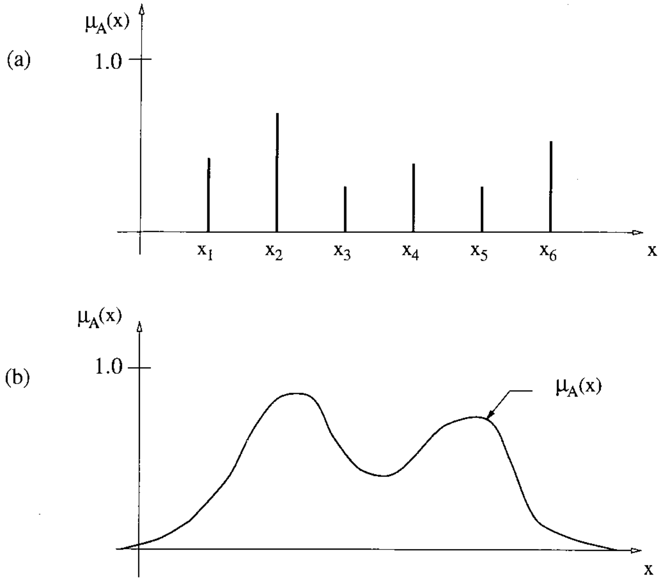

FIGURE 19.15.1 (a) Discrete and (b) continuous fuzzy set.

$$A = \{\mu_A(x_1)|x_1, \mu_A(x_2)|x_2, \ldots, \mu_A(x_n)|x_n\} \qquad (19.15.1)$$

where x_i is an element of the fuzzy set, $\mu_A(x_i)$ is its grade of membership in A, and the vertical bar is employed to link the element with their grades of membership in A. Equation (19.15.1) shows a discrete form of a fuzzy set. For a continuous fuzzy set, the membership function $\mu_A(x)$ is a continuous function of x.

Figure 19.15.1 illustrates a discrete and a continuous fuzzy set. The larger membership grade *max* $(\mu_A(x_i))$ represents the height of a fuzzy set.

If at least one element of the fuzzy set has a membership grade of 1.0, the fuzzy set is called normalized. Figure 19.15.2 illustrates both a nonnormalized and a normalized fuzzy set.

The following properties of fuzzy sets, which are obvious extensions of the corresponding definitions for ordinary (crisp) sets, are defined herein according to Zaheh (1965) and Klir and Folger (1988).

Two fuzzy sets A and B are equal, A = B, if and only if $\mu_A(x) = \mu_B(x)$ for every element x in X (see Figure 19.15.3).

The complement of a fuzzy set A is a fuzzy set $\overline{A}$ defined as

$$\mu_{\overline{A}}(x) = 1 - \mu_A(x) \qquad (19.15.2)$$

Figure 19.15.4 shows both discrete and continuous fuzzy sets and their complements.

If the membership grade of each element of the universal set X in fuzzy set B is less than or equal to its membership grade in fuzzy set A, then B is called a subset of A. This is denoted $B \subseteq A$. Figure 19.15.5 illustrates this situation.

The union of two fuzzy sets A and B with membership functions $\mu_A(x)$ and $\mu_B(x)$ is a fuzzy set $C = A \cup B$ such that

$$\mu_C(x) = \max[\mu_A(x), \mu_B(x)] \qquad (19.15.3)$$

for all x in X.

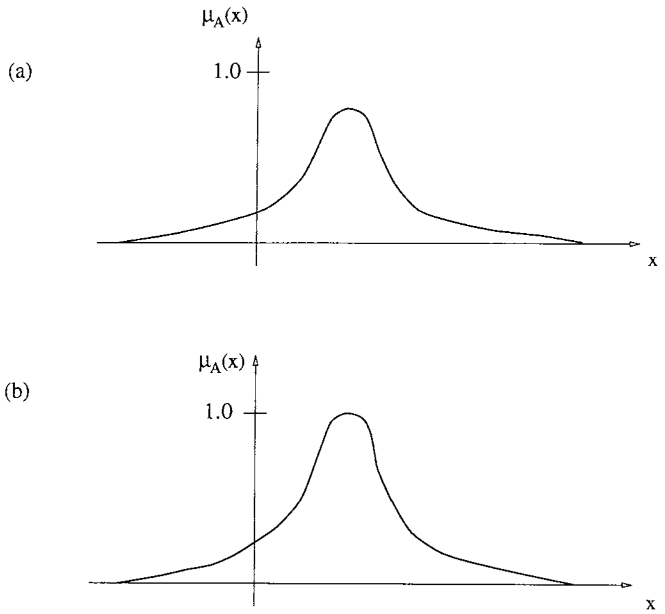

FIGURE 19.15.2 (a) Nonnormalized and (b) normalized fuzzy set.

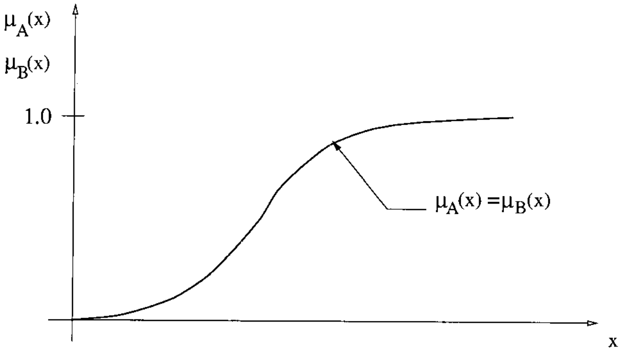

FIGURE 19.15.3 Two equal fuzzy sets, A = B.

Conversely, the intersection of two fuzzy sets A and B with membership functions $\mu_A(x)$ and $\mu_B(x)$, respectively, is a fuzzy set $C = A \cap B$ such that

$$\mu_C(x) = \min\left[\mu_A(x), \mu_B(x)\right] \tag{19.15.4}$$

for all x in X.

Figure 19.15.6 illustrates two fuzzy sets A and B, the union set $A \cup B$ and the intersection set $A \cap B$.

An empty fuzzy set A is a fuzzy set with a membership function $\mu_A(x) = 0$ for all elements x in X (see Figure 19.15.7).

Two fuzzy sets A and B with respective membership function $\mu_A(x)$ and $\mu_B(x)$ are disjoint if their intersection is empty (see Figure 19.15.8).

An α-cut of a fuzzy set A is an ordinary (crisp) set A_α containing all elements that have a membership grade in A greater or equal to α. Therefore,

$$A_\alpha = \left\{x \middle| \mu_A(x) \geq \alpha\right\} \tag{19.15.5}$$

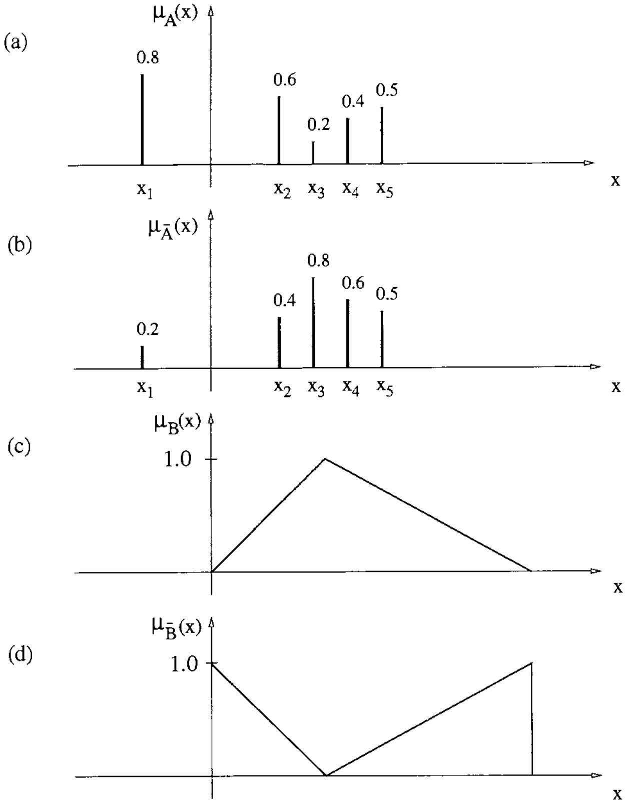

FIGURE 19.15.4 (a) Discrete fuzzy set A, (b) complement $\overline{A}$ of fuzzy set A, (c) continuous fuzzy set B, and (d) complement $\overline{B}$ of fuzzy set B.

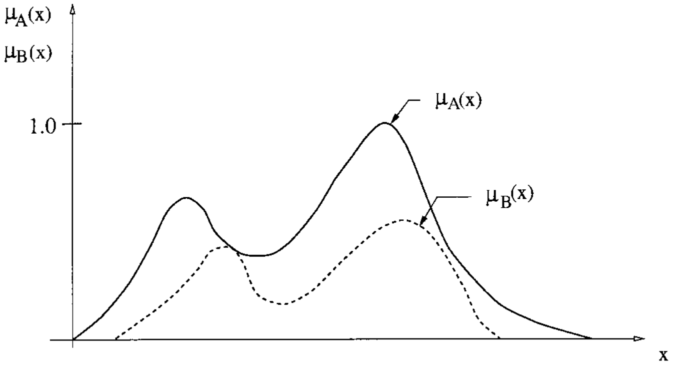

FIGURE 19.15.5 Fuzzy set A and its subset B.

From Figure 19.15.9, it is clear that $\alpha = 0.5$, the α-cut of the fuzzy set A is the crisp set $A_{0.5} = \{x_5, x_6, x_7, x_8\}$ and for $\alpha = 0.8$, the α-cut of the fuzzy set A is the crisp set $A_{0.8} = \{x_7, x_8\}$.

A fuzzy set is convex if and only if all of its α-cuts are convex for all α in the interval [0,1]. Figure 19.15.10 shows both a convex and a nonconvex fuzzy set.

A fuzzy number $\tilde{N}$ is a normalized and convex fuzzy set of the real line whose membership function is piecewise continuous and for which it exists exactly one element with $\mu_{\tilde{N}}(x_0) = 1$. As an example, the real numbers close to 50 are shown by four membership functions in Figure 19.15.11.

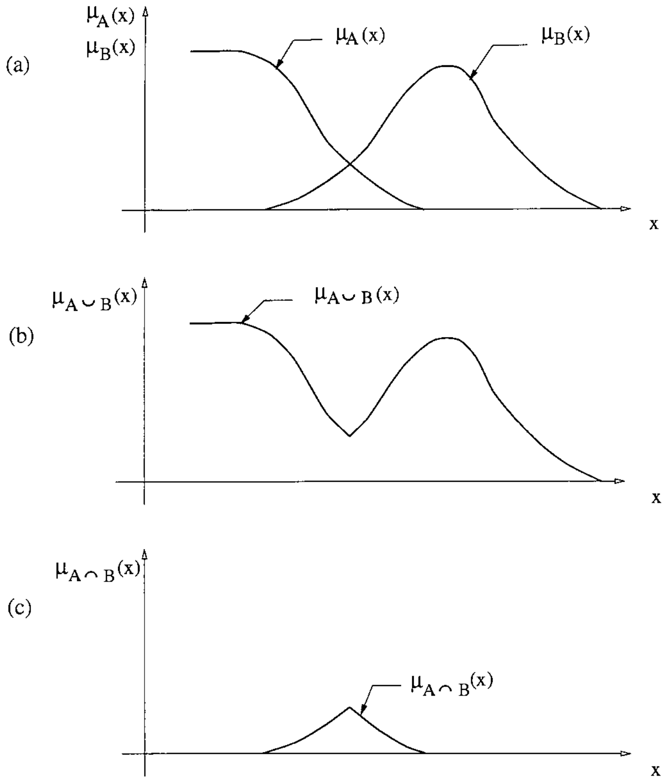

FIGURE 19.15.6 (a) Two fuzzy sets, (b) union of fuzzy sets A ∪ B, and (c) intersection of fuzzy sets A ∩ B.

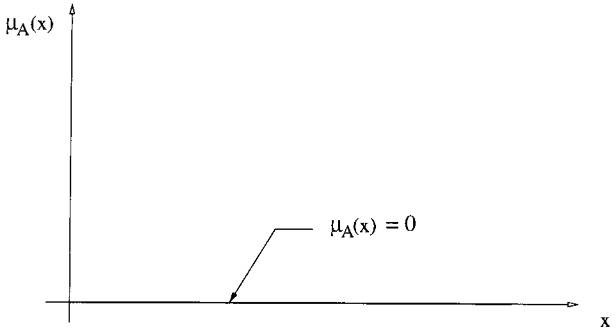

FIGURE 19.15.7 Empty fuzzy set.

The scalar cardinality of a fuzzy set A is the summation of membership grades of all elements of X in A. Therefore,

$$|A| = \sum_{x} \mu_A(x) \tag{19.15.6}$$

For example, the scalar cardinality of the fuzzy set A in Figure 19.15.4(a) is 2.5. Obviously, an empty fuzzy set has a scalar cardinality equal to zero. Also, the scalar cardinality of the fuzzy complement set is equal to scalar cardinality of the original set. Therefore,

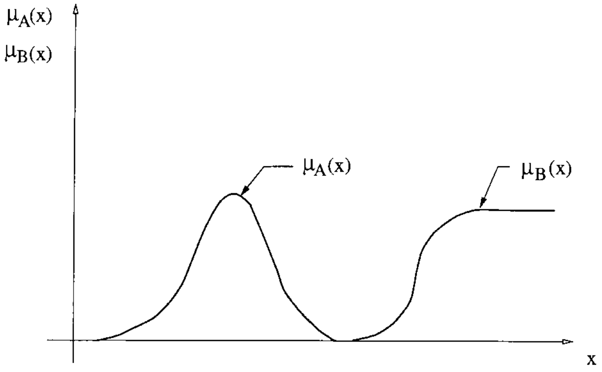

FIGURE 19.15.8 Disjoint fuzzy sets.

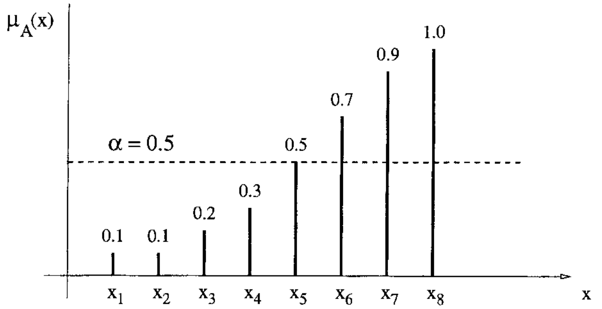

FIGURE 19.15.9 α-cut of a fuzzy set.

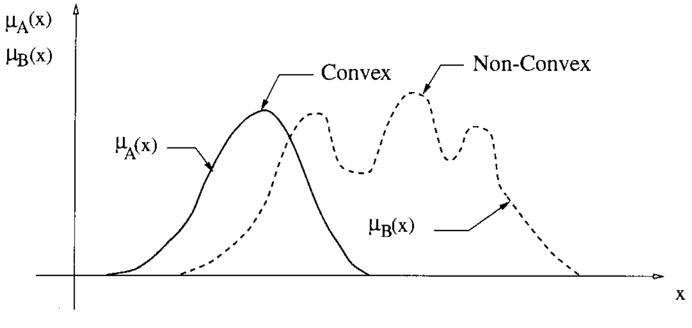

FIGURE 19.15.10 Convex and non-convex fuzzy set.

$$|A| = |\overline{A}| \tag{19.15.7}$$

One of the basic concepts of fuzzy set theory is the extension principle. According to this principle (Dubois and Prade, 1980), given (a) a function f mapping points in the ordinary set X to points in the ordinary set Y, and (b) any fuzzy set A defined on X,

$$A = \{\mu_A(x_1)|x_1, \mu_A(x_2)|x_2, \ldots, \mu_A(x_n)|x_n\}$$

then the fuzzy set B = f(A) is given as

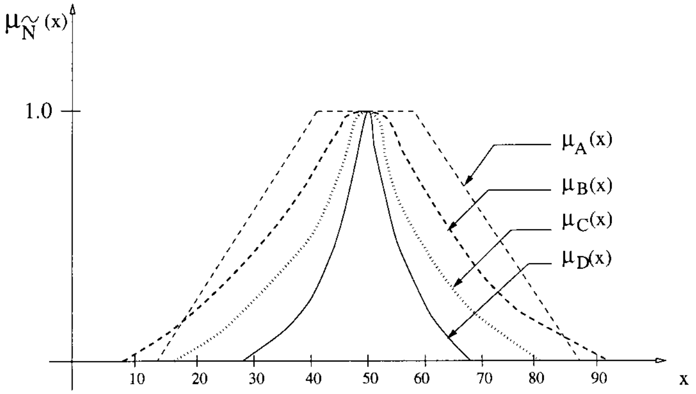

FIGURE 19.15.11 Membership functions of fuzzy sets of real numbers close to 50.

$$B = f(A) = \{\mu_A(x_1)|f(x_1), \mu_A(x_2)|f(x_2), \ldots, \mu_A(x_n)|f(x_n)\} \tag{19.15.8}$$

If more than one element of the ordinary set X is mapped by *f* to the same element y in Y, then the maximum of the membership grades in the fuzzy set A is considered as the membership grade of y in f(A).

As an example, consider the fuzzy set in Figure 19.15.4(a), where $x_1 = -2$, $x_2 = 2$, $x_3 = 3$, $x_4 = 4$, and $x_5 = 5$. Therefore, A = {0.8|–2, 0.6|2, 0.2|3, 0.4|4, 0.5|5} and $f(x) = x^4$. By using the extension principle, we obtain

$$\begin{aligned} f(A) &= \{\max(0.8, 0.6)|2^4, 0.2|3^4, 0.4|4^4, 0.5|5^4\} \\ &= \{0.8|16, 0.2|81, 0.4|256, 0.5|625\} \end{aligned}$$

As shown by Klir and Folger (1988), degrees of association can be represented by membership grades in a fuzzy relation. Such a relation can be considered a general case for a crisp relation.

Let P be a binary fuzzy relation between the two crisp sets X = {4, 8, 11} and Y = {4, 7} that represents the relational concept "very close." This relation can be expressed as:

$$P(X, Y) = \{1|(4,4), 0.7|(4,7), 0.6|(8,4), 0.9|(8,7), 0.3|(11,4), 0.6|(11,7)\}$$

or it can be represented by the two dimensional membership matrix

$$\begin{array}{cc} & \begin{array}{cc} y_1 & y_2 \end{array} \\ \begin{array}{c} x_1 \\ x_2 \\ x_3 \end{array} & \begin{bmatrix} 1.0 & 0.7 \\ 0.6 & 0.9 \\ 0.3 & 0.6 \end{bmatrix} \end{array}$$

Fuzzy relations, especially binary relations, are important for many engineering applications.

The concepts of domain, range, and the inverse of a binary fuzzy relation are clearly defined in Zadeh (1971), and Klir and Folger (1988).

The max-min composition operation for fuzzy relations is as follows (Zadeh, 1991; Klir and Folger, 1988):

$$\mu_{P \circ Q}(x, z) = \max_{y \in Y} \min[\mu_P(x, y), \mu_Q(y, z)] \tag{19.15.9}$$

for all x in X, y in Y, and z in Z, where the composition of the two binary relations P(X,Y) and Q(Y,Z) is defined as follows:

$$R(X,Z) = P(X,Y) \circ Q(Y,Z) \tag{19.15.10}$$

As an example, consider the two binary relations

$$P(X,Y) = \{1.0|(4,4),\ 0.7|(4,7),\ 0.6|(8,4),\ 0.9|(8,7),\ 0.3|(11,4),\ 0.6|(11,7)\}$$

$$Q(Y,Z) = \{0.8|(4,6),\ 0.5|(4,9),\ 0.2|(4,12),\ 0.0|(4,15),\ 0.9|(7,6),\ 0.8|(7,9),\ 0.5|(7,12),\ 0.2|(7,15)\}$$

The following matrix equations illustrate the max-min composition for these binary relations

$$\begin{bmatrix} 1.0 & 0.7 \\ 0.6 & 0.9 \\ 0.3 & 0.6 \end{bmatrix} \circ \begin{bmatrix} 0.8 & 0.5 & 0.2 & 0.0 \\ 0.9 & 0.8 & 0.5 & 0.2 \end{bmatrix} = \begin{bmatrix} 0.8 & 0.7 & 0.5 & 0.2 \\ 0.9 & 0.8 & 0.5 & 0.2 \\ 0.6 & 0.6 & 0.5 & 0.2 \end{bmatrix}$$

Zadeh (1971) and Klir and Folger (1988), define also an alternative form of operation on fuzzy relations, called max-product composition. It is denoted as P(X,Y) ⊗ Q(Y,Z) and is defined by

$$\mu_{P\otimes Q}(x,z) = \max_{y\in Y}\left[\mu_P(x,y),\ \mu_Q(y,z)\right] \tag{19.15.11}$$

for all x in X, y in Y, and z in Z. The matrix equation

$$\begin{bmatrix} 1.0 & 0.7 \\ 0.6 & 0.9 \\ 0.3 & 0.6 \end{bmatrix} \times \begin{bmatrix} 0.8 & 0.5 & 0.2 & 0.0 \\ 0.9 & 0.8 & 0.5 & 0.2 \end{bmatrix} = \begin{bmatrix} 0.8 & 0.7 & 0.5 & 0.2 \\ 0.9 & 0.8 & 0.5 & 0.2 \\ 0.6 & 0.6 & 0.5 & 0.2 \end{bmatrix}$$

illustrates the max product composition for the pair of binary relations P(X,Y) and Q(Y,Z) previously considered.

A crisp binary relation among the elements of a single set can be denoted by R(X,X). If this relation is reflexive, symmetric, and transistive, it is called an equivalence relation (Klir and Folger, 1988).

A fuzzy binary relation S that is reflexive

$$\mu_S(x,x) = 1 \tag{19.15.12}$$

symmetric

$$\mu_S(x,y) = \mu_S(y,x) \tag{19.15.13}$$

and transitive

$$\mu_S(x,z) = \max_{y} \min\left[\mu_S(x,y),\ \mu_S(y,z)\right] \tag{19.15.14}$$

is called a similarity relation (Zadeh, 1971). Equation (19.15.12), Equation (19.15.13), and Equation (19.15.14) are valid for all x,y,z in the domain of S. A similarity relation is a generalization of the notion of equivalence relation.

Fuzzy orderings play a very important role in decision-making in a fuzzy environment. Zadeh (1971) defines fuzzy ordering as a fuzzy relation which is transitive. Fuzzy partial ordering, fuzzy linear ordering, fuzzy preordering, and fuzzy weak ordering are also mathematically defined by Zaheh (1971) and Zimmermann (1991).

The notion of fuzzy relation equation, proposed by Sanchez (1976), is an important notion with various applications. In the context of the max-min composition of two binary relations P(X,Y) and Q(Y,Z), the fuzzy relation equation is as follows

$$\mathbf{P} \circ \mathbf{Q} = \mathbf{R} \tag{19.15.15}$$

where **P** and **Q** are matrices of membership functions $\mu_P(x,y)$ and $\mu_Q(y,z)$, respectively, and **R** is a matrix whose elements are determined from Equation (19.15.9). The solution in this case in unique. However, when **R** and one of the matrices **P**, **Q** are given, the solution is neither guaranteed to exit nor to be unique (Klir and Folger, 1988).

Another important notion is the notion of fuzzy measure. It was introduced by Sugeno (1977). A fuzzy measure is defined by a function which assigns to each crisp subset of X a number in the unit interval [0,1]. This member represents the ambiguity associated with our belief that the crisp subset of X belongs to the subset A. For instance, suppose we are trying to diagnose a mechanical system with a failed component. In other terms, we are trying to assess whether this system belongs to the set of systems with, say, safety problems with regard to failure, serviceability problems with respect to deflections, and serviceability problems with respect to vibrations. Therefore, we might assign a low value, say 0.2 to failure problems, 0.3 to deflection problems, and 0.8 to vibration problems. The collection of these values constitutes a fuzzy measure of the state of the system.

Other measures including plausibility, belief, probability, and possibility measures are also used for defining the ambiguity associated with several crisp defined alternatives. For an excellent treatment of these measures and of the relationship among classes of fuzzy measures see Klir and Folger (1988).

Measures of fuzziness are used to indicate the degree of fuzziness of a fuzzy set (Zimmermann, 1991). One of the most used measures of fuzziness is the entropy. This measure is defined (Zimmermann, 1991) as

$$d(A) = h \sum_{i=1}^{n} S\left(\mu_A\left(x_i\right)\right) \tag{19.15.16}$$

where h is a positive constant and $S(\alpha)$ is the Shannon function defined as $S(\alpha) = -\alpha \ln\alpha - (1 - \alpha) \ln(1 - \alpha)$ for rational α. For the fuzzy set in Figure 19.15.4(a), defined as

$$A = \{0.8|-2,\ 0.6|2,\ 0.2|3,\ 0.4|4,\ 0.5|5\}$$

the entropy is

$$\begin{aligned} d(A) &= h(0.5004 + 0.6730 + 0.5004 + 0.6730 + 0.6931) \\ &= 3.0399\ h \end{aligned}$$

Therefore, for h = 1, the entropy of the fuzzy set A is 3.0399.

The notion of linguistic variable, introduced by Zadeh (1973), is a fundamental notion in the development of fuzzy logic and approximate reasoning. According to Zadeh (1973), linguistic variables are "variables whose values are not members but words or sentences in a natural or artificial language. The motivation for the use of words or sentences rather than numbers is that linguistic characterizations are, in general, less specific than numerical ones." The main differences between fuzzy logic and classical two-valued (e.g., true or false) or multivalued (e.g., true, false, and indeterminate) logic are that (a) fuzzy logic can deal with fuzzy quantities (e.g., most, few, quite a few, many, almost all) which are in general represented by fuzzy numbers (see Figure 19.15.11), fuzzy predicates (e.g., expensive, rare), and fuzzy modifiers (e.g., extremely, unlikely), and (b) the notions of truth and false are both allowed to be fuzzy using fuzzy true/false values (e.g., very true, mostly false). As Klir and Folger (1988) stated, the ultimate goal of fuzzy logic is to provide foundations for approximate reasoning. For a general background on fuzzy logic and approximate reasoning and their applications to expert systems, the reader is referred to Zadeh (1973, 1987), Kaufmann (1975), Negoita (1985), and Zimmermann (1991), among others.

Decision making in a fuzzy environment is an area of continuous growth in engineering and other fields such as economics and medicine. Bellman and Zadeh (1970) define this process as a "decision process in which the goals and/or the constraints, but not necessarily the system under control, are fuzzy in nature."

According to Bellman and Zadeh (1970), a fuzzy goal G associated with a given set of alternatives X = {x} is identified with a given fuzzy set G in X. For example, the goal associated with the statement "x should be in the vicinity of 50" might be represented by a fuzzy set whose membership function is equal to one of the four membership functions shown in Figure 19.15.11. Similarly, a fuzzy constraint C in X is also a fuzzy set in X, such as "x should be substantially larger than 20."

Bellman and Zadeh (1970) define a fuzzy decision D as the confluence of goals and constraints, assuming, of course, that the goals and constraints conflict with one another. Situations in which the goals and constraints are fuzzy sets in different spaces, multistage decision processes, stochastic systems with implicitly defined termination time, and their associated optimal policies are also studied in Bellman and Zadeh (1970).

Further Information

The more than 5000 publications that exist in the field of fuzzy sets are widely scattered in many books, journals, and conference proceedings. For newcomers, good introductions to the theory and applications of fuzzy sets are presented in (a) *Introduction to the Theory of Fuzzy Sets,* Volume I, Academic Press, New York, 1975, by Arnold Kaufmann; (b) *Fuzzy Sets and Systems: Theory and Applications*, Academic Press, New York, 1980, by Didier Dubois and Henri Prade; (c) *Fuzzy Sets, Uncertainty and Information,* Prentice Hall, Englewood Cliffs, NJ, 1988, by George Klir and Tina Folger, and (d) *Fuzzy Set Theory and Its Applications,*, 2nd ed., Kluwer Academic Publishers, Boston, 1991, by H.-J. Zimmerman, among others.

The eighteen selected papers by Lotfi A. Zadeh grouped in *Fuzzy Sets and Applications,* John Wiley & Sons, New York, 1987, edited by R. Yager, S. Ovchinnikov, R.M. Tong, and H.T. Nguyen are particularly helpful for understanding the developments of issues in fuzzy set and possibility theory. Also, the interview with Professor Zadeh published in this book illustrates the basic philosophy of the founder of fuzzy set theory.

20.1 Patents and Other Intellectual Property

Thomas H. Young*

The purpose of this section is to provide some very general information about intellectual property protection (especially patents) to nonlawyers.** It is also intended to provide some suggestions for "self-help" to engineers that will enable them to improve the possibility of obtaining and securing appropriate protection for their ideas and developments even before they consult a lawyer. One of the questions an intellectual property attorney frequently hears is "I have a great idea. How do I protect it?" This section should provide at least a starting point for answering that question.

In the case of patents, this section is designed to assist engineers and/or inventors in understanding what is expected of them and how to assist their patent lawyers or agents in the process of protecting their inventions in the United States. Be forewarned, however; the process of obtaining patent, trade secret, and/or copyright protection on such a development is not necessarily a linear one and is often neither short nor easy.

Patents***

What is a patent? The authorization for a patent system stems from the U.S. Constitution, which provides:

> The Congress shall have power… to promote the progress of science and useful arts, by securing for limited times to authors and inventors the exclusive right to their respective writings and discoveries. (U.S. Const. Art. I, § 8)

Although the concept of a patent system did not originate in the U.S., the drafters of the Constitution thought patents and copyrights significant enough to provide for them in the fundamental predicates on which our government is founded. Indeed, Thomas Jefferson, as Secretary of State, was one of the first patent "examiners."

The premise of the constitutional provision is to encourage the disclosure of inventions in the interest of promoting future innovation. Specifically, if inventors were not provided with patent protection for their innovations, they would seek to exploit them in secret. Thus, no one else would be able to benefit from and expand on his or her inventions, so technology would not move as rapidly as it would with full disclosure. Following enactment of the Constitution, Congress promptly adopted and has continuously maintained and updated laws implementing a patent system.

* Mr. Young has practiced intellectual property law for more than 25 years, is a partner in the Denver office of the intellectual property law firm of Merchant & Gould headquartered in Minneapolis, Minnesota, and has been an adjunct professor of patent and trademark law at the University of Colorado and University of Denver law schools. The author acknowledges with appreciation the assistance of Mr. George C. Lewis, P.E., an associate at Merchant & Gould, in updating this article.

** This section is in no way intended to provide the reader with all of the information he or she may need to evaluate or obtain intellectual property protection in particular situations on their own. Additional information is available from the Patent and Trademark Office and the Copyright Office in Washington, D.C. and other published references on these subjects. For information on patents and trademarks, the reader may contact the U.S. Patent and Trademark Office, USPTO Contact Center, Crystal Plaza 3, Room 2C02, P.O. Box 1450, Alexandria, VA 22313-1450, call (703) 308-4357, or visit the Patent and Trademark Office website at www.uspto.gov. For information regarding copyrights, contact the U.S. Copyright Office, 101 Independence Ave. S.E., Washington, D.C. 20559-6000, call (202) 707-3000, or visit the Copyright Office website at www.copyright.gov. When applying the legal requirements to a specific issue, the reader is encouraged to consult with a knowledgeable lawyer.

*** The patent laws are codified in 35 United States Code (i.e., "U.S.C.") § 100 *et seq.* Regulations implementing these patent laws, particularly as they relate to the operation of the Patent Office, are found in volume 37 of the Code of Federal Regulations (i.e., "C.F.R."). The internal rules of the Patent Office relating to the examination of patents are contained in the Patent Office "Manual of Patent Examining Procedure" or "M.PE.P" For more information on patents, the following treatises may be helpful: *Chisum on Patents*, Donald S. Chisum, Matthew Bender & Co., New York, 2004; *Patent Law Fundamentals,* Peter D. Rosenberg, 2nd ed., Clark Boardman Callaghan, Rochester, NY, 1995.

Strictly speaking, patents are not contracts; however, because of the premise behind the constitutional provision, patents have sometimes been analogized to contracts between inventors and the U.S. government. The government agrees to allow the inventor exclusive rights to his or her invention for a period of time. In exchange, the inventor agrees to disclose his or her invention, thereby allowing other inventors the benefit of the patentee's work and enabling others to practice the invention after the patent has expired.

What rights does a patent confer? After a patent issues, the patentee has the right to exclude others from making, using, or selling the subject matter claimed in the patent. Currently, the term of a U.S. patent is 20 years from the date the patent application was filed. The patentee is not required to license others to use the invention.

Nevertheless, a patent does not confer the right to do anything. In fact, it is frequently the case that an inventor will receive a patent but will be unable to use the patented invention because it infringes on another's patent. For example, if A obtained the first patent on a laser and B later obtains a patent on the use of a laser in surgery, B cannot make or use the laser in surgery, because it would infringe on A's patent. By the same token, however, A cannot use his laser in surgery, because it would infringe on B's patent. In addition, patent rights are territorially limited, and the use of the same invention in different countries may have different ramifications. Finally, regardless of patent rights, the use of certain technologies (e.g., pharmaceuticals) may be limited by other government regulations and practical considerations.

A significant advantage of a patent over other forms of intellectual property protection, such as copyright or trade secret, is that a patent can be enforced against anyone who utilizes the claimed technology regardless of whether that person copied or misappropriated the technology. Independent development of an infringing device is not a defense.

Who can obtain a patent? Anyone who is the first to invent something that falls into a category of subject matter that is deemed to be patentable may obtain a U.S. patent. A single patent can have several inventors if the subject matter of one or more claims in the patent was jointly conceived or reduced to practice. In that case, each inventor, in essence, obtains his or her own rights to the patent and, in the absence of an agreement, may exploit those rights independently of the other inventor(s). The patent must be obtained by the true inventors or it may be invalid. Thus, persons who did not contribute to an invention should not be named as inventors regardless of the desirability of recognizing their moral or economic support to the process of inventing.

What subject matter is patentable? U.S. patent law provides that

> Whoever invents or discovers any new and useful *process, machine, manufacture, or composition of matter*, or any new and useful *improvement* thereof, may obtain a patent therefore, subject to the conditions and requirements of this title. (35 USC § 101 [emphasis added])

Although the categories of patentable items seem archaic, Congress acknowledged that it intended this language to "include anything under the sun that is made by man."

The development of significant new technologies, such as computers and biotechnology, has challenged the limits of proper patentable subject matter. Nevertheless, with some diversions along the way, courts have continued to expand those boundaries so that they now include computer software, engineered lifeforms and even "methods of doing business" when embodied in properly drafted patent claims. In general, however, laws of nature, scientific truths, and mathematical algorithms are not patentable subject matter in and of themselves. New and useful applications of those concepts, however, may be patented.

What are the standards for patentability? In order to merit a patent, an invention must be new, useful, and nonobvious. The "new" and "useful" standards are defined precisely as one might expect. One may not obtain a patent on an invention that has been invented before and, therefore, is not novel or on one that has no practical utility.

The "nonobvious" standard is a more difficult one. Even if an invention has not been created before, in order to be patentable, it must not have been obvious to one of ordinary skill in the technical field of the invention at the time the invention was made. In other words, a valid patent cannot be obtained on an invention that merely embodies a routine design or the application of principles within the ordinary skill of the art. Whether an invention meets the standard for nonobviousness involves a factual inquiry into the state of the art, the level of ordinary skill in the art, and the differences between what was known in the art and the invention at the time it was made. In addition, both the Patent Office and courts will look at objective evidence of nonobviousness, including the context in which the invention was made (e.g., whether or not there was a long-standing problem that had not been solved by others), recognition of the invention, and its success in the marketplace. Nevertheless, the determination of nonobviousness is not precise. Indeed, the "beauty" of many of the most significant inventions is embodied in their simplicity. As such, they are temptingly "obvious" after the fact, even though courts are theoretically constrained from utilizing hindsight in determining nonobviousness.

How is a U.S. patent obtained? The process of obtaining a patent starts with the invention. "Invention," under U.S. patent law, has two parts. First, there is the "conception" of the invention, which literally refers to the date when the inventor first thought of the novel aspect of his or her invention. Second, there is the "reduction to practice" of the invention, which can refer to a variety of activities. In the case of a mechanical invention, for example, reduction to practice occurs when a working version of the machine is built embodying the invention. However, there is also a legal concept called "constructive" reduction to practice, which occurs when the inventor files a patent application with the Patent Office.

The date of invention is very important in the U.S. Unlike every other country in the world, the U.S. awards patents to the first person to invent it, rather than the first person to file a patent application. Importantly, the date of conception serves as the date of invention in the U.S. so long as the inventor was "diligent" in reducing the invention to practice. If the inventor is not continuously "diligent" (and there is some question as to what that word means, exactly), then the date of invention is considered the date from which the inventor was continuously diligent until the invention was reduced to practice.

The date of invention can be critical to obtaining a patent in the U.S. In foreign countries, however, the only date that matters is the date on which the inventor first filed the patent application. Filing a patent application in the U.S. will normally preserve the inventor's rights abroad if the appropriate foreign patent applications are filed within one year of the U.S. filing date and the other requirements of the Patent Cooperation Treaty are met. Ideally, an inventor should file a patent application directly after the conception of the invention in order to achieve the earliest effective date in both the U.S. and abroad.

Before filing a patent application, an inventor should have a "prior art search" performed. *Prior art* is a term that refers, in part, to materials published before the inventor files the application that are relevant to the issues of novelty and nonobviousness. Having a search done for prior art is a good way to ensure that the invention for which the application is written is patentable and may also provide some insight into whether practice of the invention would infringe on the rights of others. The prior art search enables a preliminary determination of the patentability of the invention and, if it appears patentable, the identification of the patentable features to be focused upon in drafting the application. Nevertheless, there is always some prior art that will not be accessible using economically viable means at the time of application, so an inventor can never be completely sure about the novelty of his invention at the time of filing.

An inventor can apply for a patent from the Patent Office either *pro se* (i.e., on his own) or through a registered patent agent or attorney. The process of obtaining a patent is a complex one, and the inventor's chances of obtaining a valid patent of the broadest possible scope are greatly increased by the use of a qualified agent or attorney. Lists of registered patent attorneys and agents are available from the Patent Office. Patent attorneys may also be located through the *Martindale-Hubbell Law Directory,* state and local bar associations, and other publications, directories, and professional organizations.

This is not to say that inventors, themselves, have not successfully obtained patents from the Patent Office. Nevertheless, busy patent examiners are easily frustrated by *pro se* applicants' lack of familiarity with patent application requirements and Patent Office rules, and those frustrations are evidenced, consciously or unconsciously, in Patent Office "rejections." Familiarity with the stated requirements of the Patent Office and knowledge of its informal workings greatly increase the chances of successfully obtaining a valid patent with the broadest possible scope.

A patent application contains a number of parts, all of which generally fall into two main categories. The first group, known as the "specification," contains a detailed written description of the invention, including relevant drawings or graphs and any examples. The purpose of the specification is to "enable" one of ordinary skill in the art to make and use the invention. In addition, the applicant must disclose the "best mode" of practicing the invention. The "enablement" and "best mode" requirements are intended to fulfill the constitutional purpose of full disclosure of the invention. Thus, a patent that was otherwise properly granted by the Patent Office may nevertheless be invalidated if it is later determined that the inventor failed to teach others how to utilize the invention or tried to maintain the best mode of practicing the invention as a secret.

The second major part of the patent application is the "claims," which are the separately numbered paragraphs appearing at the end of a patent. The claims define the scope of protection that the patent will confer, and they must be clear, definite, and unambiguous. The goal of the applicant in prosecuting a patent is to obtain claims that cover the invention as broadly as possible without including subject matter that is obvious or not novel. For example, if A invented the two-wheeled bicycle, he might claim a vehicle utilizing two round rotating objects for conveyance. Such a claim might prove to be invalid, for example, if carts were previously known. In such a situation, it would be better to claim the bicycle more narrowly as a vehicle with two wheels in tandem.

Once the application is drafted and submitted to the Patent Office, the Patent Office classifies the invention and sends it to an appropriate "art unit." The Patent Office is divided into separate art units that employ examiners who are knowledgeable about, or at least familiar with, particular fields of technology. Eventually, an examiner will read the application, focusing mainly on the claims since they define the legal parameters of the invention. After performing his own patentability search and reviewing the application for other technical defects, the examiner may either "allow" the application to become a patent or reject the application on the grounds that it lacks substantive merit and/or fails to comply with the formalities of a proper patent application. If the examiner rejects some of the claims, he will explain why the claims are not patentable in light of the specific prior art references. This will start a series of communications (in writing, by telephone, or in person) between the examiner and the applicant (or the registered attorney of record). During that process, the claims of the patent will be amended as becomes necessary in an attempt to define patentable subject matter.

If the application is eventually allowed, then a patent will be printed and "issued" several months after payment of the "issuance fee." If the application is not allowed by the examiner and is finally rejected, the inventor can (1) abandon the application and the effort to obtain a patent, (2) file a "continuation" application and start the process over, or (3) appeal the rejection to the Board of Patent Appeals and Interferences and eventually to other courts. It is not uncommon for the process, from filing of the application until allowance, to take several years.

After the application is submitted, it is appropriate to advise the public that a patent is "pending." This remains true until the application has been abandoned or has been issued as a patent. Generally, neither the contents of the application nor even the fact that an application has been filed are publicly available from the Patent Office absent the consent of the applicant. However, the application will be published by the Patent Office approximately 18 months after filing, if the applicant pursues foreign patent protection. Although such publication will result in the loss of any trade secret protection for the technology disclosed in the application, publication does advance the date from which the applicant may obtain compensation for infringement if a patent is granted. After a patent issues, the patent number should be marked on products embodying the patent. This notice serves to start the period running for the collection of damages for patent infringement. Absent such notice, damages do not begin to run until the infringer receives actual notice of the patent.

Several aspects of this process bear particular note. First, once an application has been filed, the Patent Office does not permit the introduction of "new matter" into the application. Although typographical and other simple errors in the application may be corrected, an applicant may not insert additional written material or drawings (e.g., an additional embodiment or further improvement). The reason for this is simple — because the date of invention and the date of filing are both important for U.S. and foreign priority purposes, the Patent Office could not operate efficiently if the subject matter of the application were constantly amended. There would be numerous continuing disputes as to the effective date to be afforded the subject matter of an amended application. Instead, if it is necessary to amend the application substantively, a new "continuation-in-part" application must be filed. If it is filed while the original or "parent" application is still pending, the subject matter common to both applications will retain the original filing date, while the new material will only be afforded the filing date of the later continuation-in-part application. The prohibition on adding "new matter," therefore, places a premium on filing an original application that completely and accurately describes the invention.

Second, the patent application process frequently is not linear. Seldom does an invention constitute a static concept or a single finished embodiment. The concept may change as its full ramifications are slowly revealed through practical experience, and its embodiment in physical articles, compositions, or processes may change after the patent application is filed. Thus, as the invention evolves, it may be necessary to file further continuation-in-part applications to cover the developments that appear during this evolutionary process. To achieve the ultimate objective of obtaining patent protection on commercially viable aspects of the invention, it may be necessary for the inventor and legal counsel to reevaluate the merits of the original application and to take appropriate corrective action in the patent prosecution process.

How can the inventor help? There are a variety of ways in which the inventor can and, in fact, should aid in the process of obtaining a patent.

First, and perhaps foremost, an inventor should keep detailed notes on his research and development throughout the inventive process. All research and/or discoveries should be documented, dated, and witnessed by a noninventor because they may become important later for purposes of determining who was the first to invent. The date of invention may also be useful in convincing the Patent Office or a court that certain prior art dated before the filing of the patent application should, nevertheless, not be applied. In preparing this documentation, it is important to realize that the testimony of the inventor himself or documents authenticated only by the inventor are generally not sufficient to prove priority. There are many reasons for this. Suffice it to say that there is a premium on having the records witnessed contemporaneously by at least one noninventor. Getting a noninventor to witness pages of a lab notebook is one way to accomplish this. Alternatively, the Patent Office will, for a nominal fee, accept and retain for two years "disclosure" documents evidencing the date of conception. An inventor may also file a "provisional" patent application with the Patent Office documenting the date of invention and providing an early filing date for subject matter disclosed in that application and claimed in a full U.S. application filed during the following year. These Patent Office filings are probably the most unquestionable evidence of a date of conception.

An inventor can also assist by performing an informal prior art search of his own before contacting a patent attorney. Filing a patent application is expensive. An inventor should be as confident as possible that he has created something novel before spending the money to draft an application. Typically, a patent attorney will urge that a formal search be performed to ensure that the prior art that the Patent Office examiner is likely to access has been considered. Due to the proliferation of electronic databases for scientific and industry literature, however, there may be additional prior art that is more readily accessible to the inventor. A search of this material can be helpful to the patent attorney in isolating the patentable features of the invention and improving the chances of obtaining a valid patent.

All prior art located by or known to the inventor should be disclosed to the patent attorney so that it can be evaluated and disclosed to the Patent Office, if necessary. In that regard, both an applicant and his attorney are under an affirmative duty to disclose relevant prior art to the Patent Office, and failure to do so can lead to invalidation of the patent.

Once a prior art search has been performed, an inventor should file an application as early as practically possible. As noted previously, this will protect the inventor's rights in foreign countries as well as provide constructive reduction to practice of the invention if it has not already been embodied in a working prototype. Nevertheless, some delay in filing may be desirable in order to permit further testing and corroboration. This is permissible, and in many instances desirable, bearing in mind that under U.S. patent law an application *must* be filed within one year of the first public use, disclosure, sale, or offer of sale of the invention. This deadline cannot be extended and, if violated, will automatically result in the invalidation of the patent. Many other countries do not have a one-year "grace" period; a patent application is immediately barred once there has been a public disclosure in that country or elsewhere. Although there is an "experimental use" exception in the U.S., it is limited to technical experiments (as opposed to test marketing) that are appropriately documented. To be safe, the inventor should contact a patent attorney before publicly disclosing or using an invention or offering it for sale. If any of those events have already occurred, they should be immediately called to the patent attorney's attention.

The inventor is also instrumental in drafting the patent application. The inventor must make sure that the specification is accurate, enables one skilled in the art to practice the invention, and discloses the best way to make and use the invention. Although the art of claim drafting is somewhat of an acquired skill, the inventor should also be involved in that process to make sure that the claims cover the invention and are not easily designed around. Sometimes a patent attorney will draft claims that do not expressly state a physical element or process step, but utilize "means-plus-function" language. In that case, it is highly desirable to describe as many means as possible for fulfilling that element in the application itself, and the inventor is the best source of that type of information. In other words, the inventor should continuously be asking questions of his attorney about whether certain variations of his invention will be adequately protected by the claims as drafted. Finally, the inventor can and should be instrumental in helping the attorney identify the technical/practical differences between the invention and prior art. In short, the prosecution of a patent application should be a team effort between inventor and attorney at each step in the process.

Trade Secrets*

In some instances it may be desirable to protect new technology as a trade secret rather than by patent. For example, an invention may not be patentable; it may be one of numerous small items or know-how that improves one's business. Such items are typically protected as trade secrets. While there is no formal method of acquiring trade secret protection as there is for patents and copyrights, attention must still be paid to their identification and protection. Also, unlike patents and copyrights, trade secrets are protected under state, rather than federal, laws. Therefore, the nuances of trade secret protection may vary depending on which state's laws apply. There are, however, some general principles of trade secrets that are common to most jurisdictions.

What is a trade secret? A "trade secret" may include anything that gives a person an advantage over his competitors and is not generally known to them. It includes compilations of information such as customer lists, compositions, process techniques and parameters, and software. In determining whether something is a protectable trade secret, courts look at the following factors: (1) the extent to which the information is known outside of the trade secret owner's business, (2) the extent to which it is known by employees or others involved in the trade secret owner's business, (3) the extent of measures taken by the trade secret owner to guard the secrecy of the information, (4) the value of the information to the trade secret owner and to his competitors, (5) the amount of effort or money expended by the trade secret owner in developing the information, and (6) the ease or difficulty with which the information could be properly acquired or duplicated by others.

What protection does a trade secret provide? A trade secret protects the owner from improper appropriation of the secret through use or disclosure by a person having an obligation not to do so. The major

---

*See, generally, the Uniform Trade Secrets Act § 1(4), 14 U.L.A. 537 (1980) and *Milgrim on Trade Secrets*, Roger M. Milgrim, Matthew Bender & Co., New York, 2004.

advantage of a trade secret is that it may last indefinitely; the major defect is that if it is lost, it generally cannot be reclaimed. Unlike with patent infringement, a person accused of stealing a trade secret can successfully defend such an accusation by showing that he independently developed the subject matter of the secret. Trade secret protection, therefore, is only as good as the inability of competitors to "reverse-engineer" or to independently develop it.

How can one obtain a trade secret? Whether or not one has a trade secret is ultimately determined judicially in an action for enforcement. The court will look at all of the factors previously noted. At that time it is usually too late to take the actions necessary to establish trade secret protection. Thus, there is a premium for the periodic review and implementation of a program for trade secret protection. Steps that can be taken to protect trade secrets include (1) identifying the types of materials that are deemed to be trade secrets by an organization and notifying employees of the organization's policy to treat this information as trade secrets, (2) restricting access to the trade secrets to only those individuals who have a need to know and who are obligated by contract or otherwise not to use or disclose them, and (3) taking physical precautions to limit access to trade secrets, such as using locked file cabinets or vaults. These are the most fundamental steps that can be taken.

Although legal counsel is frequently consulted in establishing a plan for protecting trade secrets, including the drafting of appropriate confidentiality agreements, the physical steps required should be put in place by the trade secret owner prior to legal consultation.

Copyrights*

Copyright protection is usually associated with writings, songs, paintings, sculpture, and other artistic endeavors. However, it also extends to certain technology, particularly software, databases, and certain architectural plans.

What protection does a copyright provide? Copyright protection is a matter of federal law. Under the federal Copyright Act, protection is available for "original" works of appropriate subject matter, such as those mentioned in the previous paragraph. A copyright provides the exclusive right to reproduce, publicly distribute, publicly perform, publicly display, and make derivative works from an original work of authorship. However, it protects only against "copying" of the protected work and does not provide protection where a work has been independently developed by another. Copying can be presumed where the third party had access to the copyrighted work and there is "substantial similarity" between the third party's work and the original. Further, in certain limited instances, a small portion of a work may be reproduced without liability as a "fair use." The parameters of the "fair use" doctrine are complicated, however, and they are beyond the subject of this section.

Only a modicum of creativity is needed to satisfy the requirement of "originality." On the other hand, protection is limited. It has frequently been stated that a copyright only protects the manner in which something is expressed, rather than the idea or content, which can be an extremely difficult distinction to make. For example, there is significant debate as to the appropriate scope of copyright protection, for both software and databases. Nevertheless, an advantage of a copyright is that it may last for a relatively long period of time. At a minimum, copyright in works created at this time last for the life of the author plus 70 years (or 120 years if the author is a corporate entity).

How is a copyright obtained? Theoretically, in order to obtain a copyright an author need only show that a work is original to him (i.e., that he is in fact the author). Federal protection for copyright attaches as soon as a writing is fixed in a tangible medium (i.e., as soon as it is put on paper, or in memory on a

---

* The federal laws on copyright are codified in the Lanham Act, § 1 *et seq.* For further information on copyrights, the following treatise may be helpful: *Nimmer on Copyright,* Melville B. & David Nimmer, Matthew Bender, New York, 2004.

computer, or anywhere else that it can be "perceived"). Nevertheless, there are two important steps that should be taken to realize the full scope of that protection.

First, it is highly advisable to affix a copyright notice to the work. "Notice" is provided by affixing to the work: (1) the word "Copyright" or the © symbol, (2) the date of first publication, and (3) the name of the copyright owner. Notice should be affixed to the work in an obvious position (such as one of the first pages of a book, an entry screen of a computer program, etc.). A copyright notice should be placed on all drafts of material that may be subject to protection under copyright law. If an author fails to put the notice on his work, copyright protection is not lost; however, an infringer may then use the defense that he innocently thought that the work was within the public domain. Adequate notice precludes the "innocent" infringer defense, and, because it does not cost anything, notice is always a good idea.

In addition, registration of the copyright with the Register of Copyrights at the Library of Congress is also highly recommended. This procedure is relatively simple and inexpensive. It consists of filling out a government form and submitting it with the appropriate filing fee and a sample of the work sought to be copyrighted. If the application *is* acceptable, the Copyright Office returns a copy of the application stamped with the copyright registration number.

In the case of software and databases, there has been concern that an unscrupulous competitor might attempt to purloin valuable information from the sample submitted with the application. In recognition of this problem, the Copyright Office has promulgated rules allowing the submission of only a limited portion of the software or database adequate to identify the copyrighted work.

Although federal registration is not necessary to perfect a copyright, it does have some significant advantages. First, it is necessary to obtain a registration in order to bring suit against an infringer. While it is possible to register the work on an expedited basis immediately prior to commencing the lawsuit, it is not advisable. Early registration (i.e., within 3 months of the first publication of the work) allows an author to elect to sue for "statutory" damages, which can be considerably easier to prove and, possibly, more munificent than "actual" damages. In addition, an author may be able to recover attorneys' fees from a defendant in some cases, but only if the work in question was registered before or soon after publication. In sum, if an author believes that a work is important and might be copied, he should promptly register the work.

Trademarks*

Although trademark protection does not encompass technology per se, any summary of intellectual property protection would be incomplete without a few comments on the scope and availability of trademark rights.

What is a trademark? A trademark is anything that serves to identify the source of a product or service. Trademark protection can be obtained on a wide variety of items, such as words, symbols, logos, slogans, shapes (if they are not functional), tones (such as NBC's three-note tone), and even colors. A trademark owner may assert his rights against a third party that is engaged in conduct that is likely to cause consumers to believe that his goods or services emanate from, are associated or affiliated with, or are sponsored by the trademark owner.

The purpose of trademark protection is twofold: (1) to ensure the public that goods or services offered under a trademark have the quality associated with the trademark owner, and (2) to preserve the valuable goodwill that the trademark owner has established by promoting the mark. Trademark rights may last indefinitely.

How are trademark rights established? Trademarks are protected under both federal and state law. There are two ways to obtain rights in a trademark: use or federal registration. Rights in a mark can be acquired

---

* The federal trademark laws are codified at 17 U.S.C. § 1 *et seq.* For further information on trademarks, the following treatise may be helpful: *McCarthy on Trademarks and Unfair Competition*, J. Thomas McCarthy, Thomson/West, Eagan, MN, 4th ed., 2003.

simply by using the mark in connection with the goods and services. If the mark is a distinctive one (i.e., coined or "made-up" like "Polaroid"), rights are established immediately. On the other hand, if the mark is descriptive, the use must be so prominent and lengthy that the mark has acquired a "secondary meaning" (i.e., the public has come to recognize the term as identifying the source of the goods and services rather than as a reference to the product or service itself). In either case, to establish rights through use, it is desirable to use the designation ™ in connection with the mark, thereby indicating that the owner of the mark asserts that it is a trademark under common law.

In contrast, the process of obtaining a federal trademark registration involves the filing of an application with the U.S. Patent and Trademark Office. The application identifies the mark, the goods and services with which it is used, and, if it is already in use, the date of first use and the date of first use in interstate commerce. A filing fee is also required but is relatively minimal. A trademark examiner will check the application substantively, including the review of previously issued trademarks, to see if there is any conflict. If the examiner allows the application, the mark is published in the *Official Gazette,* which is a weekly publication of the Patent Office. If no one opposes the registration within 30 days after publication, then a registration will be issued. If there is an objection, then an opposition proceeding is initiated, and the applicant and the opposer essentially litigate to determine whether the applicant can obtain a trademark registration. Provided that certain documents are subsequently filed with the Patent Office to affirm and renew the registration, the registration may last indefinitely. The existence of a federally registered trademark is designated by the symbol ®, which is frequently seen on the shoulder of the mark.

A federal trademark registration is a powerful tool in protecting a trademark. By law it serves as "constructive" (i.e., assumed) notice of the registrant's claim of rights throughout the U.S. In essence, the registration acts like a recorded deed to real estate, and anyone who subsequently purchases that property without checking the recorded information does so subject to the interests of record. In contrast, the rights of one who attempts to acquire a trademark only through use are generally limited to the geographic area in which the mark is actually used. Others who subsequently use the mark in other areas of the country may also establish rights. Thus, the first step in selecting a trademark is to search the records of the Patent Office to determine whether a confusingly similar mark has previously been registered. Typically, a trademark search performed by a professional search organization will also reveal state registrations and other common law uses that might cause conflicts with the mark under consideration.

One other advantage to federal registration is that the registrant may begin to acquire protection on a mark prior to actual use. This is accomplished by filing an "intent-to-use" application on a mark that the applicant has made a *bona fide* decision to use. The application is examined as described previously. Although the mark must actually be placed in use before the registration is issued, the registration will provide rights from the date of its filing. Thus, the public is on notice of the applicant's potential rights as soon as the application is filed. The examination process will also give the applicant significant comfort that the mark is available for use before investing a great deal of money in its promotion.

Final Observations

Selecting an appropriate method of acquiring intellectual property protection for a new development may involve several forms of protection. Software, for example, may be protected by patent, trade secret, and copyright protection and may be sold using a registered trademark. In addition, other legal means may be used to protect the software, including appropriate contractual provisions limiting and restricting the rights of a user acquired by license. Those contractual commitments may survive, even if the intellectual property protection is lost.

It is hoped that this section has provided at least a general overview by which the nonlawyer can begin to understand how to protect intellectual property. There are almost never any easy answers to the question of how to protect products, ideas, and services, and it is always advisable to consult a qualified attorney with specific questions. A knowledgeable client, however, can make a significant difference in achieving the strongest protection available.

20.2 Product Liability and Safety

George A. Peters

Introduction

Almost all engineers, at some time in their career, can expect some direct contact or indirect involvement with the legal system. The contact may be in the form of having to answer written interrogatories on technical issues for a company defendant or plaintiff, being personally deposed and having to respond to oral questions under oath, appearing for a company during trial, assisting lawyers in a lawsuit, or personally being a defendant in a lawsuit. Most important is having the ability to translate legal requirements into engineering specifications to assure compliance with the law.

The old maxim "ignorance of the law is no excuse" should be supplemented by an understanding that ignorance of the law may result in unnecessary mistakes (illegal acts) and personal fear when first confronted by an unknown aspect of the legal process. It is essential that the engineer have sufficient understanding to avoid gross errors and omissions, to react appropriately to legal proceedings, and to want to build a basic foundation of knowledge that can be quickly enhanced when needed. This section is only a brief overview that might be illustrative and helpful in both understanding potential legal liability and how to avoid, prevent, or proactively minimize any such legal exposure. If product liability is legal fault for an unsafe design, the question then becomes how to achieve an appropriate level of safety.

Legal Concepts

Fundamental to determining who might be legally "at fault" is the concept of *negligence* which is utilized worldwide in the apportionment of damages (legal redress). Negligence is the failure to exercise ordinary or reasonable care, which persons of ordinary prudence would use to avoid injury to themselves or others. The exact definition is given to jurors, usually in the form of approved jury instructions (the actual operative law), who then apply the law given to them to the facts and circumstances of the case before them. The defenses to allegations of negligence (absence of due care) are, usually, *contributory negligence* (fault) on the part of the plaintiff or *assumption of the risk* on the part of the plaintiff (that risk that is specific and voluntarily assumed, not general or coerced). If there is a violation of a statute or regulation there may be a rebuttable presumption of negligence. Compliance with a technical standard may be some evidence of the exercise of due care. Concepts of *strict liability* involve the presence of a defect that legally caused personal injury or property damage. There are many definitions of a *defect*, such as a failure to perform as safely as an ordinary consumer would expect when used in an intended or reasonably foreseeable manner or "excessive preventable risks."

Foreseeability means that the personal injury, property damage, or environmental harm must have been predictable or knowable at the time of design, manufacture, or sale of the product. Generally, the law requires only *reasonable efforts* to prevent defects, deficiencies, or unsafe conditions. In other words, there should be efforts to predict possible harm and reasonably practical risk reduction efforts to minimize the harm.

The term *engineering malpractice* includes conduct that has personal legal consequences (professional liability) for the individual engineer, conduct that has adverse legal consequences for his or her employer (such as product liability or toxic torts), and conduct having moral or ethical consequences even though it may be legally protected (Peters, 1996a).

There are many other supplemental legal concepts and each state or jurisdiction has summaries of the law (Witkin, 1987–1990), approved jury instructions (Breckinridge, 1994), statutes enacted by the legislature, compendiums of case law decisions by the courts, and regulations issued by executive agencies (all of which are constantly being revised and expanded). Thus, the engineer should always consult with an attorney-at-law before making an interpretation or taking any action that might be within the province of a licensed professional.

There are thousands of technical standards issued by professional associations, trade groups, standards formulation organizations, and government agencies. Compliance with such standards is the first line of liability prevention, but such standards should be exceeded by a confortable margin to accommodate design, material, fabrication, and in-use process variance (Council, 1989). However, there are other important liability prevention measures that should be undertaken during the design process and described in a product liability prevention plan.

Risk Assessment

A central theme in liability prevention is “risk assessment”. The first step in such an assessment is to identify all probable *hazards* (those faults, failures, or conditions that could cause harm), then determine the quantitative *risk* for each (the frequency and severity of harm), and, finally, render a subjective judgment as to *danger* (the presence of excessive preventable danger). It is important to determine what kind of risk assessment is being made and to identify its objective as follows:

1. *Compliance*. The exact method of conducting a risk assessment may be specified by procurement specifications, industry standards, or government regulations. The design objective may be only compliance with the assessment requirement. However, in the process of performing a written risk assessment and classifying the risk into some severity level, it may result in a beneficial safety audit of the product. Where there is “residual risk,” the design of specific warnings and instructions may be required.
2. *Major Compliance Tasks*. Where safe performance is very important, a detailed engineering analysis may be required by contract or regulation. This might involve listing all probable hazards for each component, part, and subsystem, then attempting to quantify the risk estimate for each hazard at the 10^{-6} level of attempted precision. Since this requires a major effort, the primary design and management objective should be product improvements and informed product assurance.
3. *Comparative Analysis*. Some risk assessments involve only an overall risk estimate which is then compared with other similar products or a wide range of products. The objective or use may be for marketing purposes or liability defense. Since the results are gross or macroscopic, such risk assessments generally do not result in product improvement.
4. *Risk Ratings*. Some trade associations may provide generic risk ratings for materials or products. The objective may be for an “informed choice” of procedures and field equipment in order to satisfy a legal “duty of care” or to help determine the “best practical means” of job performance.
5. *System Effectiveness*. Some risk assessments are performed early in the design process, perhaps as part of a reliability analysis, for the purpose of predicting final system effectiveness. The objective may be to check design efforts, reallocate available funds, or refocus management audits to achieve a desired level of system effectiveness. The process may be used to assure that desired system-of-systems performance is achievable.

From the societal viewpoint, some level of risk can be tolerable, acceptable, required, and specified. What is desired at a given locality or time period can be made known by the local common law, government regulations, trade standards, practices, customs, and expectations. From the engineering viewpoint, *risk levels are controllable, adjustable, manageable, and a consequence of the application of appropriate engineering techniques, skills, and information resources.*

Engineering Analysis

Rather than rely only upon an engineer’s subjective and often biased judgment as to what constitutes a safe design, it is advisable to perform specific objective engineering analyses for design safety. This usually includes some systematic approach to identifying failure modes and field hazards, their risk consequences, and alternative design options that might improve the safety performance. This should be supplemented by formal design review sessions that consider information from or about customers and learned intermediaries in the fabrication, packaging, shipping, distribution, and marketing system. Written hazard analyses should include consideration of legal duties (Peters, 1991a,b), liability prevention techniques (Peters, 1996b), and cultural attributes and technical information resources in the worldwide marketplace (Murakami, 1987, 1992). There should be a systems perspective, a cradle-to-ultimate-disposal philosophy, a true understanding of customer needs and characteristics, and appropriate application of specific design safety techniques.

Testing is required to *verify* the engineering analyses, to *prove* the inherent safety of the product or process system, and to *discover* all potential problems before they become manifest postsale. As part of a *product liability mitigation plan*, procedures and costs should be determined for possible accident investigations, product recalls, retrofits, and injury reparations. A continuing (postsale) *product surveillance plan* should cover all foreseeable users, servicing, maintenance, repair, modification, transport, disposal, and recycling of the product and its components. This permits early discovery and resolution of safety problems. It should also include a means for updating a knowledge bank of scientific, engineering, legal, insurance, patent, and foreign standards information useful for future design efforts as well as postsale obligations.

Human Error

Human error is a major source of undesirable variance in human–machine interfaces. Unfortunately, many engineers neglect or virtually ignore the human factors aspects of product and system design. There should be some effort to control human performance and prevent human failure by designing for a wide range of human dimensions, characteristics, and predictable responses (Peters, 1996a). If possible, the physical attributes, kinetics, and creative perceptual abilities of human operators, maintenance and repair personnel, and bystanders should be utilized in design. Human factors should be part of any early engineering analysis, with appropriate testing and safeguarding for human error that cannot otherwise be eliminated. This includes mechanical guards, tamper-resistant features, safe-stop and limited movement switches, proximity sensors with directional control, built-in time for protective behavioral reactions, and the prevention of inadvertent activation and operation. One of the most important sources of helpful information on human error comes from incident and accident reconstruction, but the scope and bias of the inquiry may severely limit the design usefulness of the data obtained; for example,

1. The *fatalistic approach* where human error is considered as being inevitable in an imperfect world. If there is "no fault" other than by the person committing an error or omission, there is little incentive to investigate in detail to determine other factors for purposes of corrective action. This fosters the continuance of tolerable human error, persistent undesirable human error, and a lack of true recognition of causation and preventive actions.
2. The *behavioral approach* which has a focus on individual behavior in an attempt to develop "safer people," safer attitudes, and to develop motivation to "act responsibly." This may result in closer supervision and additional training, with some short-term benefits, but it does not permanently alter the error-inducing situation.
3. The *situational approach* to human error is to blame the situation, the work environment, group interactions, sociotechnical factors, and the overall circumstances of the situation. There is some benefit from a broader perspective to human error since it provides a better understanding of causation.
4. The *product design approach* has an emphasis on the interaction between the user and the engineered product to provide information useful to the design engineer.
5. The *multifactorial approach* is based on the assumption that there is multiple causation for each injury, damage, loss, harm, or error. If special attention is given to each substantial factor or cause, valuable design-oriented information can result. This multifaceted perspective of accident reconstruction has the greatest benefit and is compatible with concepts of pure comparative negligence and the allocation of damages in proportion to the degree of fault.

During any accident investigation or accident reconstruction, care should be exercised to prevent any "spoliation" or distruction of evidence. This requires trained specialists, since even slight changes to the product may obliterate information that becomes critical in later product evaluations.

Warnings and Instructions

As a last resort, for residual risk, appropriate use of warnings and instructions is essential for product liability prevention and the safe use of products (Peters, 1993). Such communications require a specific design engineering effort, plus relevant testing, if they are to be effective. They include warning devices, warnings on labels and packaging, material safety data sheets, instructions for training, insertions in owner's or operator's manuals, and postsale advertisements and letters to all owners. Some regulations require that they be in two languages and in nonlanguage pictorials. Such hazard communications and procedural directions should not be the result of a cursory afterthought, but an ongoing integral part of the design process. There may be neuropsychological considerations in the presentation of information by visual or auditory displays, machine condition and status indicators, and computer-generated information that requires specialized knowledge and testing. The basic premise is to design a referent about a specific hazard so the target individual is adequately informed as to risk and has a reasonable choice as to avoidance behavior. Warnings that fail to communicate their intended message are functionally useless. There is considerable scientific and engineering information regarding the design of warnings and instructions, and the failure to heed such information may result in legal allegations about a failure to warn, instruct, test, or appropriately market a product. The issue becomes what proof exists about whether or not warnings, instructions, or representations would have significantly influenced user behavior, purchaser choices (as, for example, in available options), and use of protective equipment. Warnings are an important liability prevention and design safety objective.

Liability Prevention

Some corporate enterprises elect to have no formal, organized product safety or liability prevention programs. They rely upon common sense, what is quickly deemed necessary, past practices and procedures, and efforts to motivate or convince all employees that everyone is responsible. This offers great future uncertainty in a growing dynamic and changing marketplace. Other companies may offer the illusion of a meaningful program by virtue of provisions in company policy statements, operating manuals, and designated individuals at high levels. The implementation often fails to provide sufficient early design safety assurance to management, timely opportunities to make design improvements that emerge from focused analytic and test efforts, and interactive contact with the user or customer base. Many companies have developed effective programs that are customized to their needs, customs, value systems, and product mix. In some instances, a liability mitigation effort may shift toward liability prevention, product or system safety marketing advantages, or expand to include health effects and environmental considerations.

An important information resource is trade standards that can be used for design guidance. Generally, these are minimum consensus requirements formulated by a select group of interested individuals. Since they are minimum, and are dated, they should be used as checklists in a standards-plus manner. Some are directly applicable standards, but there are also a myriad of peripheral standards that may be of utility in design review, subcontractor purchasing, and general liability avoidance. These are voluntary, but there are other standards that may be more mandatory. Government standards, recommendations, and laws may be local, state or provincial, or national. Awareness of progress in internationally harmonized standards is important because of the potential global reach of marketing and prediction of legal requirements over the life of a product. There are also design specifications, operative legal concepts, and other design requirements. The question is how to efficiently consolidate and make available such requirements.

The design process should be objectively auditable, with design alternatives presented in a system context for management review and decisions. The audit process could include responsible supervision sign-offs, periodic interdepartmental design reviews, independent system safety analysis, and progressive testing. Postproduction changes should be subject to appropriate administrative controls and to evaluations on a system and actual usage basis.

Special means should be provided for the control of variance on all safety critical functions and derivative parameters. Some of the factors that should be considered are costs associated with various actions, internal and outsourcing manufacturing capability and reliability, and likely perturbations during the operating life of the product, installation, its disposal, repair, rebuilding, servicing, disposal, and possible recycling. Also for potential modifications, buyback, and recalls. In other words, an overview as to how product consistency, durability, and product performance can be assured and what the acceptable limits may be in terms of customer expectation and satisfaction. Of particular importance are the actual effects of outsourcing, multiple factory production, and variance control in different geographical, cultural, and technological areas.

In assessing the costs and benefits of various design alternatives, subjectivity should be replaced where possible with objective estimates. Crude categories may be uninformative or misleading and should be avoided. The failure effects to be considered might include property damage, mission or business interruption, repair or replacement costs, company reputation damage, and personal injury. The injuries should be explored and described with some particularity since the details may be relevant both as to severity and possible remedies. This will also permit a realistic set-aside or monetary reserve for contingencies associated with product misadventure or failure. This permits a more intelligent approach to insurance deductibles, insurance limits, self-insurance and excess insurance or monetary reserve probabilities.

Communication is an important attribute of a product liability prevention program. It is not unusual for the responsible design engineers to be unaware or poorly informed of prior failures, malfunctions, problems, complaints, or adverse verdicts. Entry level engineers may repeat mistakes made earlier and subsequently corrected. There may be regular cycles of relearning from the duplication of design issues and their resolution by design studies. In essence, is there an effective method of experience retention and timely recovery? How is such information effectively communicated to *all* engineers involved in relevant design decisions? How is it translated, if necessary, for communication to suppliers, customers, or users? Are local languages, customs, and practices important determinants in communicating avoidance behavior, or constructive actions? Many engineers attempt to avoid or limit their activities relative to written, inferential, or symbolic communications, so special persons may need to be assigned to such tasks or to review the possible effect of the communications.

Determining the causation of problems, complaints, incidents, and accidents provides a valuable source of information for design corrective and preventive action. To yield useful information, a causation analysis must be performed to some detailed level in accordance with established procedures. Simple conclusions as to causation or subjective cursory opinions are usually nonproductive. It takes a depth of understanding to determine all the causal factors that could have design and management interest. Since each incident investigator or accident reconstructionist is biased to some degree and perceives the facts according to their own personal interests, it is wise to have a representative of design engineering present in at least a fair sample of incidents and accidents. If a design safety focused engineer perceives and integrates the facts of an accident, that specialist is more likely to derive helpful design safety implications and findings before there are repeat accidents. Typical cross-departments barriers or limitations to the flow of information may be relieved by utilizing independent or staff engineers for accident reconstruction and external problem resolution. Eithics should trump information management when the company and customer interest should prevail.

Therefore, liability prevention is premised on specifications and standards (design goals), design and development audits (management awareness and choice), variance control (consistency and predictability), communication (knowledge utilization), causation (problem correction), and life cycle costs (reasonable reduction). Each of these considerations can be further elaborated or implemented in a specific fashion depending on the size of the enterprise, its contractual commitments, and the sophistication of its design, production, and distribution procedures. It is well to remember that history has shown that some companies have suffered financial distress or gone bankrupt because of product safety problems while equivalent or similar companies have avoided such problems and have propsered.

Despite beliefs to the contrary, the legal liability system in each country is based on fault. The law provides an economic incentive to try to avoid complaints of fault. It motivates efforts to achieve a reasonable and practical level of safety. Appreciable risk may be assumed by the excessive permissible use of critieria such as tolerable risk and acceptable risk, because these concepts are ambiguous, can be improperly defined, and may vary in meaning in various jurisdictions and countries. Design safety is the true antidote to legal liability. Sufficient safety can be achieved by an effective liability prevention program.

20.3 Biomechanics

B. Johan Ivarsson, Jeff R. Crandall, Gregory W. Hall, and Walter D. Pilkey

The field of biomechanics applies the theories and methods of classical mechanics to biological systems. More precisely, it is concerned with the forces that act on and within a biological structure and with the

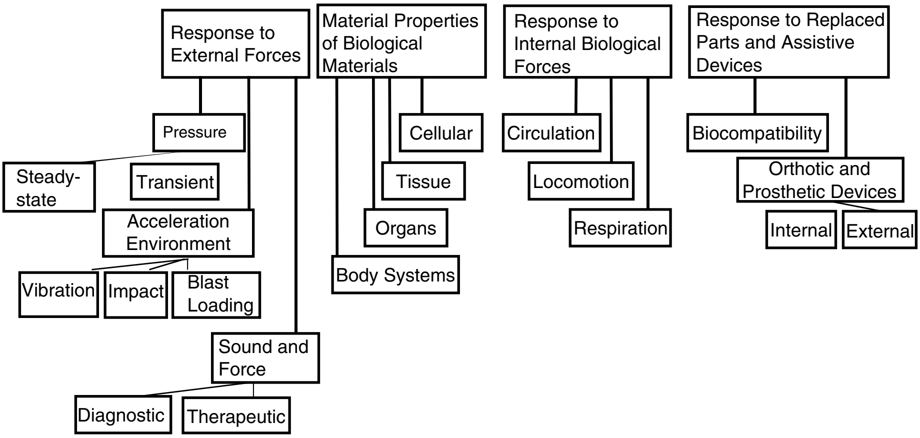

FIGURE 20.3.1 Topics of biomechanics.

effects that these forces produce. An overview of topics within the field of biomechanics is provided in Figure 20.3.1. Due to the vast breadth of the field, the authors of this section have not attempted to provide an exhaustive overview of the field of biomechanics. Instead, the section aims to provide a review of material properties of human tissues and factors affecting those properties, as well as brief introductions to the branches of biomechanics known as human body vibrations, impact biomechanics, and computational biomechanics.

Material Properties of Human Tissues

Bone Tissue Mechanics

The term *bone* refers to two types of hard tissue structure: cortical and cancellous bone. Cortical bone is the dense, structured compact bone that comprises the shaft of long bones such as the femur and tibia. Cancellous or trabecular bone is found within the ends of the long bones and the body of the irregularly shaped bones. The mechanical and structural properties of the two types of bone can vary substantially, depending on testing methods as well as such factors as age, gender, and anatomical location. In addition, bone is capable of **remodeling** in response to its environment. Table 20.3.1 summarizes general physical and material properties for the two bone types.

Like most biological materials, bone behaves as an anisotropic, nonhomogeneous, viscoelastic material. Therefore, the values in Table 20.3.1 exhibit a wide range of scatter and variability due to the simplified model of bone as a linearly elastic isotropic material. It is generally adequate, however, to model bone as a linearly elastic anisotropic material at the strain rates found in most experiments. To address the anisotropy, bone is generally considered to exhibit either transverse isotropic or orthotropic behavior. The constitutive equation for a linearly elastic material can be written using a single-index notation for stress and strain as

$$\sigma_i = c_{ij}\varepsilon_j \tag{20.3.1}$$

TABLE 20.3.2 Transverse Isotropic Material Constants for Cortical Bone from the Human Femur[a]

Model	E_1 (GPa)	E_2 (GPa)	E_3 (GPa)	G_{12} (GPa)	G_{13} (GPa)	G_{23} (GPa)	ν_{12}	ν_{13}	ν_{23}	ν_{21}	ν_{31}	ν_{32}
TI	11.5	11.5	17.0	3.6	3.3	3.3	0.58	0.31[b]	0.31[b]	0.58	0.46	0.46

[a] Direction 3 coincides with the long bone axis; the 1 and 2 directions are radial and circumferential, respectively.

[b] Not measured (determined from the relationship: $\nu_{13} = \nu_{23} = (E_1 \times \nu_{31})/E_3$).

Source: Reilly and Burstein (1975)

where the standard summation convention is used with the indices possessing a range of 6. The stress-strain relationship can be similarly expressed in terms of the compliance matrix S_{ij} such that

$$\varepsilon_i = S_{ij}\sigma_j \tag{20.3.2}$$

Equation 20.3.3 represents the compliance matrix of an orthotropic material in terms of the Young's moduli (E_i), the Poisson's ratio (ν_{ij}), and the shear moduli (G_{ij}).

$$\mathbf{S}_{ij} = \begin{bmatrix} 1/E_1 & -\nu_{21}/E_2 & -\nu_{31}/E_3 & 0 & 0 & 0 \\ -\nu_{12}/E_1 & 1/E_2 & -\nu_{32}/E_3 & 0 & 0 & 0 \\ -\nu_{13}/E_1 & -\nu_{23}/E_2 & 1/E_3 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1/G_{23} & 0 & 0 \\ 0 & 0 & 0 & 0 & 1/G_{31} & 0 \\ 0 & 0 & 0 & 0 & 0 & 1/G_{12} \end{bmatrix} \tag{20.3.3}$$

For an orthotropic material, the compliance matrix can be expressed in terms of 12 components, 9 of which are independent. The additional symmetry of the transverse isotropic model results in a further simplification with

$$E_1 = E_2,\ \nu_{12} = \nu_{21},\ \nu_{13} = \nu_{31},\ G_{23} = G_{31},\ E_1 = 2G_{12}\,(1 + \nu_{12}) \tag{20.3.4}$$

The anisotropy of bone requires that it is tested in several directions in order to determine all of the independent elastic coefficients. Table 20.3.2 provides experimentally obtained transverse isotropic material constants for cortical bone from the human femur (Reilly and Burstein 1975).

Soft Tissue Mechanics

The biomechanical properties of soft tissues depend on both the chemical composition and the structure of the tissue. Most soft tissue structures within the body demonstrate aspects of nonhomogeneous, anisotropic, nonlinear viscoelastic behavior. Given the complexity of the constitutive equations and testing *in-vivo*, the material properties are difficult to measure. To simplify the test procedures, homogeneity and linearity are frequently assumed.

The simplest representation of viscoelastic material behavior uses combinations of discrete models consisting of linear springs and dashpots: the Maxwell model and the Kelvin (or Voigt) model. While these models are generally linear approximations of the nonlinear behavior of biological materials, they can often describe material behavior with reasonable accuracy and can help to visualize tissue behavior.

For improved characterization of the soft tissue response, Fung (1993) developed an approximate theory that was based on the theory of linear viscoelasticity but incorporated nonlinear stress-strain characteristics. More complex nonlinear viscoelastic models can provide additional improvements in describing tissue response but require extensive experimental testing to determine the model coefficients.

TABLE 20.3.3 Physical and Biomechanical Properties of Human Articular Cartilage

Density (kg/m^3)	Ultimate Tensile Strength (MPa)	Ultimate Elongation (%)	Tensile Modulus (MPa)	Indentation Stiffness (MPa)	Poisson's Ratio	References
1300	2–40[a]	60–120[b]	3–224[a, c]	4.8–8.4[d]	0–0.4[e]	20,24,29,50,56

[a] Specimens from the superficial and mid-depth cartilage layers of the human femoral head and talus loaded in the direction of the predominant alignment of the collagen fibers in the superficial layer.

[b] Bovine articular cartilage specimens from the superficial, mid-depth, and deep zone layers loaded in the directions of 0, 45, and 90° from the axis of split-line patterns.

[c] Calculated as the slope of the stress-strain curve at Lagrangian stresses of 1 and 10 MPa.

[d] From in-vivo indentation testing on arthroscopy patients.

[e] Applies to the solid matrix of articular cartilage.

Cartilage

In most joints of the body, the ends of the articulating bones are covered with a dense connective tissue known as hyaline articular cartilage. The cartilage is composed of a composite organic solid matrix that is swollen by water (75% by volume). The cartilage serves to distribute load in the joints and to allow relative movement of the joint surfaces with minimal friction and wear. The coefficient of friction for articular cartilage in human synovial joints has been reported to be in the range 0.005 to 0.04 (Mow and Soslowsky 1991).

Some physical and biomechanical properties of articular cartilage are summarized in Table 20.3.3. The experiment of preference for the testing of articular cartilage has historically been the indentation test. Analysis of the test results has used elastic contact theory, the correspondence principle, and the assumption of material incompressibility ($\nu = 0.5$). This analysis ignores the nonhomogeneous and directional properties of articular cartilage and does not take into account considerable finite deformational effects or the flow of the interstitial fluid relative to its porous permeable solid matrix. More recent models of cartilage have used bi-phasic (an elastic solid and a fluid phase) or tri-phasic approach to describe more accurately the mechanical response of cartilage.

Muscle

Three types of muscle comprise the muscular system: cardiac muscle, smooth or involuntary muscle, and skeletal or voluntary muscle. The focus of this section will be on the skeletal muscle used to maintain the body's posture and to provide movement of the body's segments. The response of skeletal muscle is determined by a combination of active and passive components. The force exerted by a muscle is dependent on the length at which it is stimulated, on the velocity of contraction, on the duration of contraction, and on such factors as fatigue, temperature, and prestretching. A general estimate of the strength of the muscle assumes that its strength is proportional to the physiologic cross-sectional area, defined as the muscle volume divided by its true fiber length. The average unit force per cross-sectional area that is exerted by a muscle ranges from 20 to 80 N/cm^2. For more precise calculations, the relationship between the maximum force of muscle and instantaneous rate of change of its length must be considered. Hill's equation is an empirical relationship expressing the rate of muscle shortening as a function of the isotonic force

$$V = \frac{b\left(F_0 - F\right)}{F + a} \quad \text{or} \quad F = \frac{F_0 b - av}{b + v} \qquad (20.3.5)$$

where V is the velocity of shortening, F_0 is the force at zero velocity (isometric condition), and F is the instantaneous force. The constants a and b have units of force and velocity, respectively, and are determined empirically using relationship 20.3.6.

TABLE 20.3.4 Biomechanical Properties of Human Ligaments and Tendons[a]

Tissue	Ultimate Tensile Strength (MPa)	Ultimate Elongation (%)	Tensile Modulus (MPa)	References
Ligament	7.4–52.7	5–44	65.3–1060	5,15,25,27,30,36,37,39,42–45,52
Tendon, patellar	17–78	14–31	239–660	3–5,14,23,40

[a] All values obtained in tests in which the ligament and tendon specimens were loaded in the longitudinal direction (the direction of the predominant alignment of the collagen fibers)

$$K = \frac{a}{F_0} = \frac{b}{V_{\max}} \tag{20.3.6}$$

where $V_{\max} = bF_0/a$, the shortening velocity against no load. For most muscles, the range of the muscle constant is $0.15 < K < 0.25$ (McMahon 1987).

Tendons and Ligaments

Tendons and ligaments are connective tissues composed primarily of collagen fibers and are normally loaded in tension. Tendons transmit forces from muscles to bone in order to

- Execute joint motion
- Store energy

Ligaments attach articulating bones across a joint in order to

- Guide joint movement
- Limit the joint range of motion
- Maintain joint congruency
- Assist in providing joint stability

The biomechanical properties of ligaments and tendons are summarized in Table 20.3.4.

The general stress-strain behavior of connective soft tissue can be represented by four distinct loading regions (Figure 20.3.2). Region I is commonly referred to as the “toe region” and is associated with the straightening or alignment of the randomly ordered structural fibers. Most physiologic loading occurs in this region where there is a small increase in stress for a given increase in strain. Region II characterizes the linear region where the straightened fibers are more uniformly loaded. The tangent to the stress-strain response curve in this linear region is frequently referred to as the elastic stiffness or tensile modulus

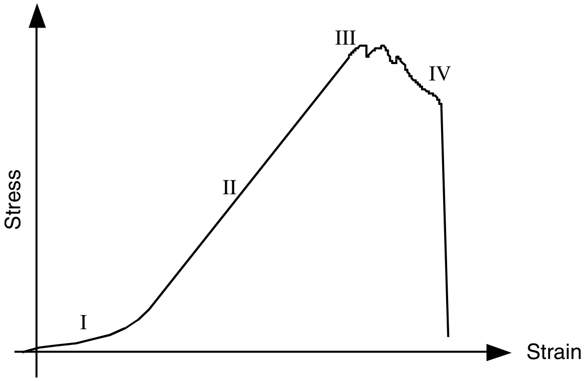

FIGURE 20.3.2 General stress–strain behavior of connective soft tissue.

rather than the elastic modulus in order to emphasize that the soft tissue is not truly behaving as a perfectly elastic material. At the initiation of Region III, small fluctuations in the stress can be observed resulting from microfailures in the soft tissue. The final loading profile, shown in Region IV, exhibits catastrophic failure of the soft tissue.

Factors Affecting Biomechanical Properties

Due to the nature of biological testing, a great deal of variability in the material properties of tissue is evident in the published literature. Unlike traditional engineering materials, there are no standard protocols or procedures for the testing of biological materials. Although some variability can be attributed to differences in the experimental approaches undertaken by the researchers, mechanical behavior of biological materials can also be affected by

- Geometric characteristics
- Loading mode (i.e., tension, compression, torsion)
- Rate and frequency of loading
- Specimen preparation (i.e., temperature, preservation method, hydration)
- Age or health of specimen donor
- Gender
- Temperature
- Anatomical location of load and specimen
- Species

Rate of Loading. All biological materials show, to some extent, viscoelastic material properties, which means that they demonstrate increased stiffness and strength with increased loading rate. Several experimental studies have reported that the stiffness and strength of human cortical and cancellous bone are approximately proportional to the strain rate raised to the power of 0.05 to 0.07 and 0 to 0.07, respectively (McElhaney 1966; Carter and Hayes 1976, 1977; Carter and Caler 1983; Linde et al. 1991; Ouyang et al. 1997). In addition to influencing the material properties, the rate of loading can also affect the patterns of failure of biological materials.

Loading Mode. The stress-strain behavior of biological materials is highly dependent on the orientation of the tissue structure with respect to the direction of loading (Table 20.3.5). Many tissues, such as cortical bone, tendon, and muscles, have organized structures that result in anisotropy of the physical properties. In some cases, the anisotropy exists but due to the complexity and increased variability of the data, it is not incorporated in the constitutive model or experiments.

Anatomic Location. Although homogeneity is often assumed, biological tissues typically exhibit significant differences in material properties depending on the anatomic location. Table 20.3.6 illustrates the variability of material properties with anatomic location using the human meniscus.

TABLE 20.3.5 Material Properties Variation in Human Femoral Cortical Bone Due to Specimen Orientation and Loading Mode

Orientation	Loading Mode	Elastic Modulus (GPa)	Ultimate Strength (MPa)	Ultimate Strain (%)
Longitudinal	Tension	17.4	133	3.1
	Compression	18.2	193	1.9
	Shear	3.3	68	0.33[a]
Transversal	Tension	12.7	51	0.7
	Compression	11.7	133	5.8

TABLE 20.3.7 Ratio of Age Changes for Ultimate Tensile Strength of Various Human Tissues

Tissue	10–19 years	20–29 years	30–39 years	40–49 years	50–59 years	60–69 years	70–79 years
Femoral cortical bone	0.93	1.00	0.98	0.91	0.76	0.70	0.70
Costal cartilage	1.02	1.00	0.93	0.80	0.56	0.33	0.29
Muscle tissue (Rectus Abdominis)	1.27	1.00	0.87	0.73	0.67	0.60	0.60
Calcaneal tendinous tissue	1.00	1.00	1.00	1.00	1.00	0.95	0.78
Skin	1.00	1.00	1.54	1.54	1.40	1.27	1.07

Source: Yamada (1970)

Age. The material properties of biological materials can vary depending on whether the specimens are obtained from immature, mature, or aging tissue. In general, the ultimate strength of tissues decreases with increasing age. Bone, cartilage, muscle, tendon, and ligaments all show decreases in the ultimate strength and elastic moduli after maturity with increasing age (Table 20.3.7). Several tissues, such as skin and teeth, are exceptions to this general rule and can exhibit increases in some material properties with age.

Storage/Preservation. The increasing complexity of biomechanical testing requires a considerable period of time for each individual test and necessitates tissue storage and preservation. It is essential to ensure that the storage and preservation of biological materials are controlled so that the material property measurements in the laboratory accurately reflect the properties of the tissue in the living state. Biological materials are preserved using one of three methods depending on the required storage interval:

- Refrigeration for short-term storage
- Freezing for long-term storage
- Embalming for long-term storage

Refrigeration and freezing have virtually no effect on the properties of bone tissue. The effects of refrigeration on soft tissue properties, however, are tissue dependent. Freezing of soft tissue can cause ice cavities that disrupt the tissue architecture and result in property changes. The effects of embalming on soft and bone tissue structures exhibit conflicting results depending on the embalming technique, concentrations, duration, and tissue type.

Because many biological materials are composed primarily of water, humidity strongly influences the stress-strain relationships (Table 20.3.8). Therefore, care must be taken to keep biological specimens moist prior to and during testing. The control of the moisture level of specimens is most important when

TABLE 20.3.8 Comparison of Material Properties Between Wet and Dry Tibial Cortical Bone from Humans 20–39 Years of Age

Test Condition	Ultimate Tensile Strength (MPa)	Ultimate Elongation (%)	Elastic Modulus (GPa)
Wet	140.3 ± 1.2	1.50	18.1
Dry	170.7 ± 1.2	1.29	20.6

analyzing the elastic properties of surface tissues such as skin and hair. Young's modulus of skin at 25% to 30% relative humidity may be 1000-fold greater than that at 100% humidity (Duck 1990).

Species. Animal tissues have been used extensively in biomechanical testing due to their availability. When extrapolating results to humans, care must be taken since significant differences can exist in the structure and material properties between humans and animals due to physiologic and anatomic differences. Table 20.3.9 shows a comparison of some physical and biomechanical properties of bone specimens obtained from human and different animals.

Human Body Vibrations

The human body treated as a viscoelastic mechanical system possesses natural frequencies and accompanying resonant responses. Standards (primarily ISO) are available for determining whole body vibrations and for measuring and predicting the health effects of these vibrations (Griffen 1998). Typically the vibration characteristics of the whole human body are obtained with a person on a shake table (Wei and Griffen 1998). Numerous models, mostly lumped mass models, have been developed to represent the dynamics of humans (Smith 2000). Normally, a shake table is used for studying whole body vibrations, whereas analytical models often are employed to study body part dynamics. The human resonant frequencies found in the literature vary widely, largely because of the variability of human subjects, the difficultly of identifying biofidelic models, and the inaccessibility of many body parts. Some natural frequency ranges for the human body are provided in Table 20.3.10. The values in this table should be treated as being approximate, since the dynamics of internal organs is complex and the results depend on many factors, including the orientation of the person subjected to the excitation (von Gierke and Brammer, 1998).

The interaction of the human and a structure is of major concern since activating a resonant vibration in the human can have adverse effects (Table 20.3.11). For example, both the performance of a machine and the health of its operator depend on the proper control of the dynamic characteristics of the system. A vibration isolator needs to account for the biomechanical properties of the human as well as the dynamic properties of the structure, perhaps over a wide frequency range (Frolov and Furman, 1990 and Balandin et al. 2001).

Impact Biomechanics

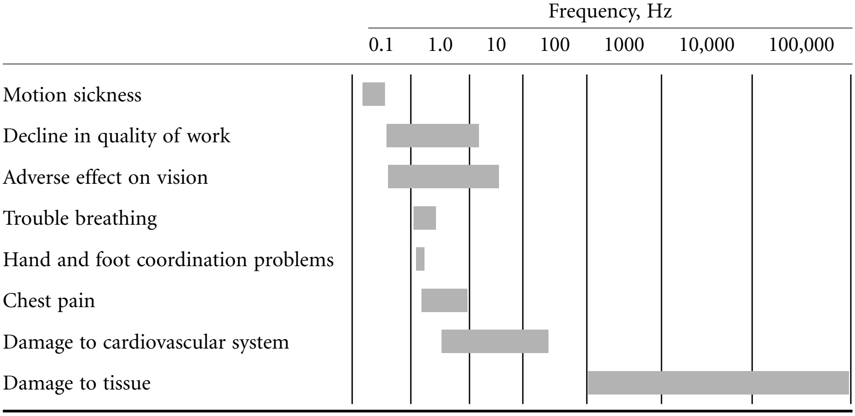
The prevention of injury through the development of countermeasures is most effectively achieved through biomechanical testing and analysis. The prevalence of injuries resulting from motor vehicle

TABLE 20.3.10 Resonant Frequencies of the Human Body

Organ	Resonant Frequencies
Whole Body	
Vertical	
Sitting	4–6 Hz
Standing	6–15 Hz
Horizontal on rigid slab	
Longitudinal	1–3.5 Hz
Head	8–40 Hz
Eyes	12–17 Hz
Face and Jaws	4–27 Hz
Throat	6–27 Hz
Chest	2–12 Hz
Lumbar portion of spinal column	4–14 Hz
Shoulders	4–8 Hz
Lungs	4–8 Hz
Abdomen	4–12 Hz
Hands, feet	2–8 Hz
Arms with hands	20–70 Hz

Sources: Frolov and Furman (1990), Sachse et al. (2003), Duarte et al. (2003), von Gierke and Brammer (1998)

TABLE 20.3.11 Vibration Frequency Effects on Humans



Sources: Frolov and Furman (1990), von Gierke and Brammer (1998)

crashes, sporting activities, and industrial accidents has led to the development of a branch of biomechanics referred to as *impact biomechanics*. In order to achieve the principal aims of prevention of injury through environmental modification, this branch of biomechanics must develop an improved understanding of the mechanisms of injury, descriptions of the mechanical response of the biological materials involved, and information on the human tolerance to impact. Injury criteria for the human body as interpreted by the 50th percentile adult male Hybrid III anthropometric crash test dummy are provided in Table 20.3.12. The injury criteria are provided in terms of engineering parameters of resultant acceleration $a(t)$, displacement $s(t)$, force $F(t)$, and moment $M(t)$.

Computational Biomechanics

Computational mechanics provides a versatile means of analyzing biomechanical systems. Modeling uses either rigid body models composed of rigid masses, springs, joints, and contact surfaces or flexible body models with finite or boundary elements (Table 20.3.13). Software is now available that incorporates the

TABLE 20.3.12 Injury Criteria for the Automotive Impact Environment as Specified for the 50th Percentile Adult Male Crash Test Dummy Hybrid III in Federal Motor Vehicle Safety Standard No. 208

Body Region	Injury Criterion	Formulation	Threshold
Head	Head Injury Criterion (HIC)[a]	$\mathrm{HIC} = (t_2 - t_1)\left[\frac{1}{(t_2 - t_1)}\int_{t_1}^{t_2} a(t)\,dt\right]^{2.5}$	1000/700
Chest	Resultant thoracic acceleration	$a(t)$	60 g[b]
	Compressive deflection of the sternum relative to the spine	$s(t)$	63 mm[c]
Neck	$\mathrm{N_{ij}}$	$N_{ij}(t) = (F_z(t)/F_{zc}(t)) + (M_y(t)/M_{yc}(t))$[d]	1.0
	Peak tension force	$F_z(t)$	4170 N
	Peak compression force	$F_z(t)$	4000 N

[a] t_1 and t_2 are any two points in time ($t_2 > t_1$) separated by no more than 36 ms (threshold = 1000) or 15 ms (threshold = 700). In the formulation for *HIC*, the acceleration $a(t)$ must be expressed in g.

[b] $a(t)$ may exceed 60 g for intervals whose cumulative duration is not more than 3 ms.

[c] The current version of FMVSS 208 includes the proposed value of 63 mm and the old value of 76 mm.

[d] $F_{zc} = 6806$ N when $F_z > 0$. $F_{zc} = -6160$ N when $F_z < 0$. $M_{yc} = 310$ Nm when $M_y > 0$ (when a flexion moment exists at the occipital condyle). $M_{yc} = -135$ Nm when $M_y < 0$ (when an extension moment exists at the occipital condyle).

TABLE 20.3.13 Comparison of Rigid Body and Finite Element Modeling Methods

Model Characteristics	Multibody Model	Finite Element Method
Complexity	Relatively simple	Relatively complex
Fidelity	Requires engineering intuition	Can achieve high fidelity
Efficiency	Efficient	Computationally expensive
Model elements	Springs, point masses, rigid bodies, ellipsoids, joints, and contact planes	Flexible elements: bricks, beams, plates, shells

two modeling techniques and uses multibody modeling to capture overall kinematics of a biomechanical system and flexible body modeling to provide an in-depth study of those regions of particular interest.

The complexity of biological systems and limited constitutive model data often requires simplifying assumptions be made during the development of models. Therefore, it is necessary to verify the model before conducting parametric and sensitivity studies.

20.4 Mechanical Engineering Codes and Standards

Michael Merker

What Are Codes and Standards?

A **standard** can be defined as a set of technical definitions, requirements, and guidelines for the uniform manufacture of items; safety; and/or interchangeability. A **code** is a standard that is, or is intended to be, adopted by governmental bodies as one means of satisfying legislation or regulation. Simply put, standards can range from a general set of minimum requirements to very specific "how-to" instructions for designers and manufacturers.

Voluntary standards, which can run from a few paragraphs to hundreds of pages, are written by experts who sit on the many committees administered by standards-developing organizations (SDOs), such as ASME International. They are not considered voluntary because they are created by volunteers; rather, they are voluntary because they serve as guidelines but do not of themselves have the force of law. ASME International publishes its standards, accredits users of standards to ensure that they have the capability of manufacturing products that meet those standards, and provides a stamp that accredited manufacturers may place on their products, indicating that they were manufactured according to the standard. ASME International cannot, however, force any manufacturer, inspector, or installer to follow ASME International standards. Their use is voluntary.

Why are voluntary standards effective? Perhaps the American Society for Testing and Materials (ASTM) said it best in its 1991 annual report: "Standards are a vehicle of communication for producers and users. They serve as a common language, defining quality and establishing safety criteria. Costs are lower if procedures are standardized; training is also simplified. And consumers accept products more readily when they can be judged on intrinsic merit."

A dramatic example of the value and impact codes and standards have had on our society is provided by ASME International's Boiler and Pressure Vessel Code. Toward the end of the nineteenth century, boilers of every description, on land and at sea, were exploding with terrifying regularity for want of reliably tested materials, secure fittings, and proper valves. They would continue to do so into the twentieth century. Engineers could take pride in the growing superiority of American technology, but they could not ignore the price of 50,000 dead and 2 million injured by accidents annually.

The mechanical engineers who tackled the problems in 1884 began by seeking reliable methods for testing steam boilers. The need for the establishment of universally accepted construction standards would take many more years and resulted in the first edition of the Boiler and Pressure Vessel Code being published by ASME International in 1915.

Codes and Standards—Related Accreditation, Certification, and Registration Programs

Accreditation

Shortly after the Boiler Code was first published, the need emerged for a recognizable symbol to be affixed to a product constructed in accordance with the standards. ASME International commissioned appropriate seals that are now the internationally acknowledged symbols of the society. The symbol is stamped onto the product.

But how does a manufacturer obtain permission to use one of the symbols? Through the ASME International **accreditation** process, the manufacturer's quality control process is reviewed by an ASME International team. If the quality control system meets the requirements of the applicable ASME International code or standard and the manufacturer successfully demonstrates implementation of the program, the manufacturer is accredited by ASME International. This means that the manufacturer may certify the product as meeting ASME International standards and may apply the stamp to the product.

The stamp consists of a modified cloverleaf (from the shape of the ASME International logo), with letter(s) in the center. The letter(s) indicate the code or section of the code met by the product upon which it is placed. Boiler and pressure vessel stamps issued are

A — Assembly of Power Boilers
E — Electric Boilers
H — Heating Boilers, Steel Plate, or Cast-Iron Sectional
HV — Heating Boiler Safety Valves
HLW — Lined Potable Water Heaters
M — Miniature Boilers
N — Nuclear Components
NPT — Nuclear Component Partial
NA — Nuclear Installation/Assembly
NV — Nuclear Safety and Pressure Relief Valves
PP — Pressure Piping
RP — Fiber-Reinforced Plastic Pressure Vessels
S — Power Boilers
U, U2, U3 — Pressure Vessels
UD — Rupture Disk Devices
UM — Miniature Pressure Vessels
UV, UV3 — Pressure Vessel Safety Valves
V — Boiler Safety Valves

ASME International also has accreditation programs for nuclear materials, authorized inspection agencies, organizations that certify elevator inspectors, and reinforced thermoset plastic corrosion-resistant vessels.

Certification

ASME International has also expanded its scope of activity to cover **certification** of individuals. The first program became available in 1992 and covered the qualification and certification of resource-recovery facilities operators. It has since added programs to cover operators of hazardous waste incinerators, medical waste incinerators, and fossil fuel–fired plants. A program to certify an individual's knowledge and ability in the area of geometric dimensioning and tolerancing has also been added.

Registration

Registration is similar to accreditation; however, it is the term used more frequently in the international arena, particularly when dealing with the International Organization for Standardization (ISO) 9000 program on quality assurance systems. ASME International's ISO 9000 Registration Program has been accredited by the American National Accreditation Program for Registrars of Quality Systems (ANSI-RAB) and the Dutch Council for Certification (RvC) in the following industrial sectors:

Primary metals industries
Fabricated metal products
Industrial and commercial machinery and equipment
Reinforced thermoset plastic tanks and vessels
Engineering services

How Do I Get Codes and Standards?

Role of ASME International in Mechanical Engineering Standards

ASME International is a nonprofit educational and technical organization with more than 125,000 members, most of whom are practicing engineers. About 20,000 are students. ASME International has a wide variety of programs: publishing, technical conferences and exhibits, engineering education, government relations, and public education, as well as the development of codes and standards, all aimed at serving the engineering profession, the public, industry, and government.

The ASME International Board of Governors has delegated the codes and standards activity to a 22-member Council on Codes and Standards, which directs all aspects of the program. Under the Council are ten boards, also made up of ASME International members and other interested persons; supervisory boards in turn oversee committees, each responsible for a specific area of standard development.

Committees in one form or another have dealt with standards since the first test code in 1884. Currently, there are more than 100 main committees dealing with over 600 standards that are under regular review and revision. Once a standard is accepted, it is printed and made available to manufacturers, regulatory agencies, designers — anyone with an interest in that particular subject. Close to 3800 individuals serve on these committees and their subcommittees, subgroups, and working groups.

After a standard has been considered and reconsidered at meetings and through many drafts, it is sent to the main committee, representing all interests, which votes on the standard. But this is not the final step. Before the draft becomes a standard and is published and ready for distribution, it is made available for public comment and must be approved by the appropriate ASME International supervisory board. This process is illustrated graphically in Figure 20.4.1. ASME International has been a consistent supporter of the policy of prior announcement of meetings, open meeting rooms, **balanced committees**, public announcements and reviews, appeal mechanisms, and overall procedural **due process**.

Role of ANSI in These and Other Related Standards

In 1911, ASME International was one of a number of organizations that recommended the establishment of an organization to help eliminate conflict and duplication in the development of voluntary standards in the U.S. Such an organization was formed in 1918 and is currently known as the American National Standards Institute (ANSI). ANSI is the U.S. member of the ISO and the administrator of the U.S. National Committee of the International Electrotechnical Committee (IEC). The intent of obtaining ANSI approval of a standard is to verify that in establishing the standard, the originating organization has followed principles of openness and due process and has achieved a consensus of those directly affected by the standard.

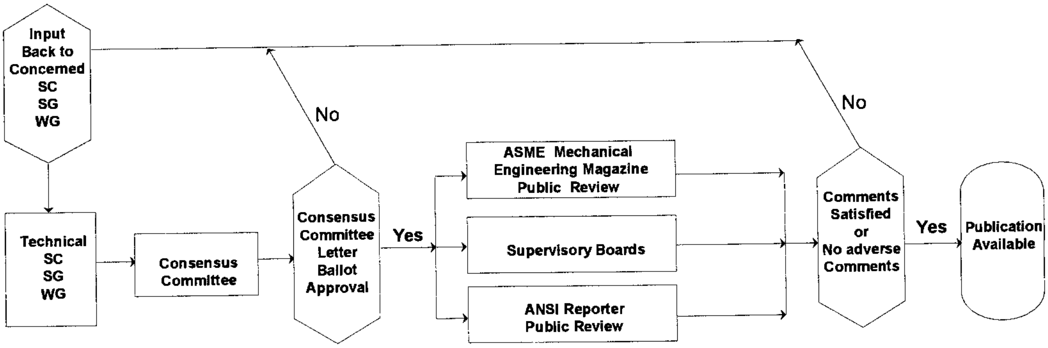

FIGURE 20.4.1 A typical path for standards approval.

What Standards Are Available?

List of Topics Covered by ASME International Standards

The following is a list of topics that are covered by ASME International Standards:

Abbreviations
Accreditation
Air-Cooled Heat Exchangers
Air Cylinders and Adapters
Air Heaters
Atmospheric Water Cooling Equipment
Automatically Fired Boilers
Automotive Lifting Devices
Backwater Valves
Boilers
Bolts
Building Services Piping
Cableways
Cargo Containers
Carriers
Castings and Forgings
Centrifugal Pumps
Chemical Plant and Petroleum Refinery Equipment
Chucks and Chuck Jaws
Cleanouts
Coal Pulverizers
Compressors
Consumable Tools
Conveyors
Coordinate Measuring Machines
Cranes
Deaerators
Density Determination
Derricks
Dial Indicators
Diaphragm Seals
Dies
Diesel and Burner Fuels
Digital Systems
Dimensional Metrology
Dimensioning and Tolerancing
Drafting
Drains
Dumbwaiters
Ejectors
Elevators
Escalators
Exhausters
Fans
Fasteners
Feedwater Heaters
Fittings
Flanges
Floor Drains
Flue Gas Desulfurization
Fluid Flow in Pipes
Fuel Gas Piping
Gage Blanks
Gage Blocks
Gas Flow Measurement
Gas Transmission and Distribution Piping Systems
Gas Turbine Power Plants
Gas Turbines
Gaseous Fuels
Gaskets
Gauges
Graphic Symbols
Hand Tools
High Lift Trucks
Hoists
Hooks

Hydroelectric Equipment
Incinerators
Indicated Power
Industrial Sound
Industrial Trucks and Vehicles
Internal Combustion Engine Generator Units
Ion Exchange Equipment
Jacks
Keys
Keyseats
Knurling
Letter Symbols
Lifts
Limits and Fits
Line Conventions and Lettering
Linear Measurements
Liquid Transportation Systems
Low-Lift Trucks
Machine Guarding
Machine Tools
Manlifts
Material Lifts
Measurement
Mechanical Power Transmission Apparatus
Mechanical Springs
Metric System
Milling Machines
Model Testing
Monorails
Moving Walks
Nuclear Facilities and Technology
Nuts
Oil Systems
Optical Parts
Pallets
Particulate Matter
Performance Test Codes
Pins
Pipe Dimensions
Pipe Threads
Piping
Pliers
Plumbing
Pressure Transducers
Pressure Vessels
Pumps
Quality Assurance
Reamers
Refrigeration Piping
Resource Recovery Facility Operators
Retaining Rings
Risk Assessment
Rivets
Safety and Relief Valves
Screw Threads
Screws
Slings
Slip Sheets
Solid Modeling
Spray Cooling Systems
Stainless Steel Pipe
Stands
Steam-Generating Units
Steel Stacks
Storage/Retrieval Machines
Storage Tanks
Surface Texture
Temperature Measurement
Thermometers
Tools
Transmission Apparatus
Transmission Chains
Turbines
Valves
Washers
Waste Facility Operators
Water Hammer Arresters
Weighing Scales
Welded Aluminum-Alloy Storage Tanks
Wheel Dollies
Wheelchair Lifts
Whirlpool Bathtub Appliances
Wind Turbines
Wrenches

Where Do I Go if the Subject I Want Is Not on This List?

With the constant creation and revision of standards, not to mention the large number of different SDOs, it is impractical to search for standards-related information in anything other than an electronic format. The latest information on ASME International's codes and standards can be found on the World Wide Web (WWW). ASME International's home page is located at http://www.asme.org. It contains a searchable catalog of the various codes and standards available for immediate download in a Portable Document Format (PDF) format and contains information on drafts out for public review and committee meeting schedules, as well as general information about the other areas ASME International is involved with. Another useful Web site is provided by the National Standards System Network (NSSN). This is a project that is still under development, and whose goal is to present a comprehensive listing of all bibliographic information on standards and standards-related material. The NSSN page is located at http://nssn.org. This site is also useful in that it provides links to many of the SDO's Web sites.

Defining Terms

Accreditation: The process by which the ability of an organization to produce a product according to a specific code or standard is evaluated. It is not an actual certification of a specific product, but does provide a third-party evaluation of the manufacturer's competence to certify that individual products are in compliance with the applicable standards.

Balanced committee: A committee in which the consensus body responsible for the development of a standard comprises representatives of all categories of interest that relate to the subject (e.g., manufacturer, user, regulatory, insurance/inspection, employee/union interest). A balanced committee ensures that no one interest group can dominate the actions of the consensus body.

Certification: The process by which an individual's training or abilities to perform a task according to a specific code or standard is evaluated.

Code: A standard that is, or is intended to be, adopted by governmental bodies as one means of satisfying legislation or regulation.

Consensus: This means that substantial agreement has been reached by directly and materially affected interest groups. It signifies the concurrence of more than a simple majority, but not necessarily unanimity. Consensus requires that all views and objections be considered and that an effort be made toward their resolution.

Due process: A procedure by which any individual or organization who believes that an action or inaction of a third party causes unreasonable hardship or potential harm is provided the opportunity to have a fair hearing of their concerns.

Registration: Similar to accreditation, it is the term used more frequently in the international arena, particularly when dealing with the ISO 9000 program on quality assurance systems.

Standard: A set of technical definitions, requirements, and guidelines for the uniform manufacture of items; safety; and/or interchangeability.

Further Information

The Engineering Standard, A Most Useful Tool, by Albert L. Batik, is a comprehensive work covering the impact of standards in marketing and international trade as well as their application to traditional areas such as design, manufacturing, and construction.

The Code: An Authorized History of the ASME Boiler and Pressure Vessel Code, by Wilbur Cross, provides an in-depth look at events that led to need for codes and the pioneers who created the Boiler and Pressure Vessel Code.

20.5 Optics

Roland Winston and Walter T. Welford (Deceased)

Geometrical Optics

Geometrical optics is arguably the most classical and traditional of the branches of physical science. By the time Newton wrote his *Principia*, geometrical optics was already a highly developed discipline. Optical design of instruments and devices has been worked out and improved over the centuries. From the telescopes of Galileo to the contemporary camera lens, progress while impressive has been largely evolutionary with modern design benefiting enormously from the availability of fast, relatively inexpensive digital computers. It is noteworthy that even in the last 20 years progress has been made by extending

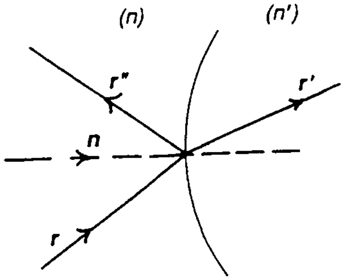

FIGURE 20.5.1

the classical model to problems where image formation is not required, or desired. We shall touch on these developments of "nonimaging optics" later in this section. But first we treat classical geometrical optics. In this model, a "point source" emits rays which are straight lines in a vacuum or in a homogeneous isotropic dielectric medium. Light travels at different speeds in different dielectrics. Its speed is given by c/n, where c is the speed in vacuum (299,792,458 m sec^{-1}) and n, the *refractive index*, depends on the medium and on the frequency of the light.

A ray is refracted at an interface between two media. If **r** and **r′** are unit vectors along the incident and refracted directions, n and n' are the respective refractive indexes, and **n** is the unit normal to the interface, then the ray directions are related by

$$n\mathbf{n} \times \mathbf{r} = n'\mathbf{n} \times \mathbf{r}' \tag{20.5.1}$$

which is the law of refraction, *Snell's law*, in vector form. More conventionally, Snell's law can be written

$$n \sin I = n' \sin I' \tag{20.5.2}$$

where I and I' are the two angles formed where the normal meets the interface, the angles of incidence and refraction. The two rays and the normal must be coplanar. Figure 20.5.1 illustrates these relationships and shows a reflected ray vector $\mathbf{r}''$. Equation (20.5.1) can include this by means of the convention that after a reflection we set n' equal to $-n$ so that, for reflection,

$$\mathbf{n} \times \mathbf{r} = -\mathbf{n} \times \mathbf{r}'' \tag{20.5.3}$$

With a bundle or pencil of rays originating in a point source and traversing several different media, e.g., a system of lenses, we can measure along each ray the distance light would have traveled in a given time t; these points delineate a surface called a *geometrical wavefront*, or simply a *wavefront*. Wavefronts are surfaces orthogonal to rays (the Malus–Dupin theorem). (It must be stressed that wavefronts are a concept of geometrical optics and that they are *not* surfaces of constant phase, phase fronts, of the light waves in the scaler or electromagnetic wave approximations. However, in many situations the geometrical Earth are a very good approximation of phase fronts.) Thus, if successive segments of a ray are of length d_1, d_2, …, a wave front is a locus of constant Σnd or, passing to the limit, $\int n\, dl$. This quantity is called an *optical path length*. (See Figure 20.5.2.)

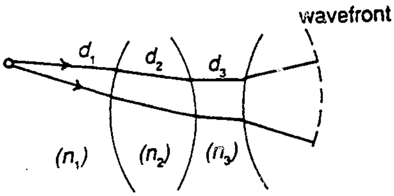

FIGURE 20.5.2

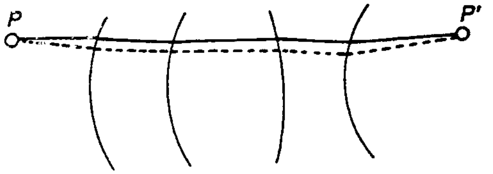

FIGURE 20.5.3

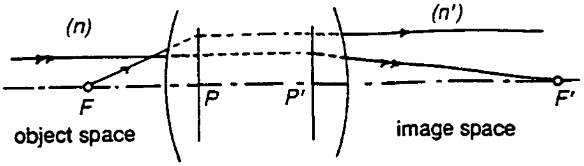

FIGURE 20.5.4

Optical path lengths enter into an alternative to Snell's law as a basis for geometrical optics. Consider any path through a succession of media from, say, P to P'. We can calculate the optical path length W from P to P', and it will depend on the shape of this path, as shown in Figure 20.5.3. Then *Fermat's principle* states that, if we have chosen a physically possible ray path, the optical path length along it will be stationary (in the sense of the calculus of variations) with respect to small changes of the path. (The principle as originally formulated by Fermat proposed a *minimum* time of travel of the light. Stationarity is strictly correct, and it means roughly that, for any small transverse displacement δx of a point on the path, the change in optical path length is of order δx^2.) For our purposes, Fermat's principle and Snell's law are almost equivalent, but in the case of media of continuously varying refractive index it is sometimes necessary to invoke Fermat's principle to establish the ray path. Apart from such cases, either one can be derived from the other.

Either Fermat or Snell can be used to develop the whole edifice of geometrical optics in designing optical systems to form images.

Symmetrical Optical Systems

The axially symmetric optical system, consisting of lenses and/or mirrors with revolution symmetry arranged on a common axis of symmetry, is used to form images. Its global properties are described in terms of *paraxial* or *Gaussian* optics. In this approximation only rays making small angles with the axis of symmetry and at small distances from the axis are considered. In Gaussian optics, we know from symmetry that rays from any point on the axis on one side of the system emerge on the other side and meet at another point on the axis, the *image point*. This leads to the well-known formalism of principal planes and focal planes shown in Figure 20.5.4. A ray entering parallel to the axis passes through F', the second, or image-side, principal focus on emerging from the system, and a ray entering through F, the first principal focus, emerges parallel to the axis. A ray incident on the first, or object-side, principal plane P at any height h emerges from the image-side principal plane P' at the same height h so that the principal planes are *conjugated* planes of unit magnification. Excluding for the moment the special case

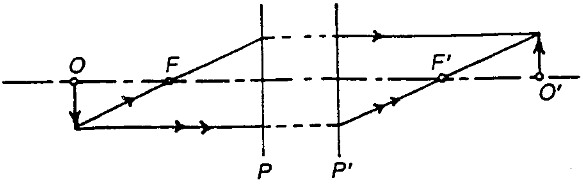

FIGURE 20.5.5

in which a ray entering parallel to the axis also emerges parallel to the axis, these four points yield a useful graphical construction for objects and images, as depicted in Figure 20.5.5.

The two focal lengths f and f' are defined as

$$f = PF, \qquad f' = P'F' \tag{20.5.4}$$

Their signs are taken according to the usual conventions of coordinate geometry, so that in Figure 20.5.4 f is negative and f' is positive. The two focal lengths are related by

$$n'/f' = -n/f \tag{20.5.5}$$

where n and n' are the refractive indexes of the object and image spaces, respectively.

Conjugated distances measured from the principal planes are denoted by l and l', and the conjugate distance equation relating object and image positions is

$$n'/l' - n/l = n'/f' = -n/f \tag{20.5.6}$$

The quantity on the right — that is, the quantity on either side of Equation (20.5.5) — is called the *power* of the system, and is denoted by K.

Another form of the conjugate distance equation relates distances from the respective principal foci, z and z'.

$$zz' = ff' \tag{20.5.7}$$

This equation yields expressions for the transverse magnification:

$$\eta'/\eta = -f/z = -z'/f' \tag{20.5.8}$$

This is useful to indicate paraxial rays from an axial object point O to the corresponding image point O' as in Figure 20.5.6 with convergence angles u and u' positive and negative, respectively, as drawn in the figure. (Paraxial angles are small but diagrams like Figure 20.5.6 can be drawn with an enlarged transverse scale. That is, convergence angles and intersection heights such as h can all be scaled up by the same factor without affecting the validity of paraxial calculations.) Then, if η and η' are corresponding object and image sizes at these conjugates, the following relation exists between them:

$$nu\eta = n'u'\eta' \tag{20.5.9}$$

In fact, for a given paraxial ray starting from O, this quantity is the same at any intermediate space in the optical system. That is, it is an invariant, called the Lagrange invariant. It has the important property that its square is a measure of the light flux collected by the system from an object of size η in a cone of convergence angle u.

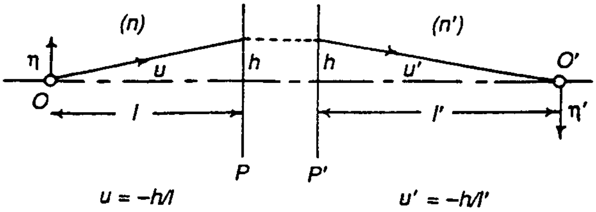

FIGURE 20.5.6

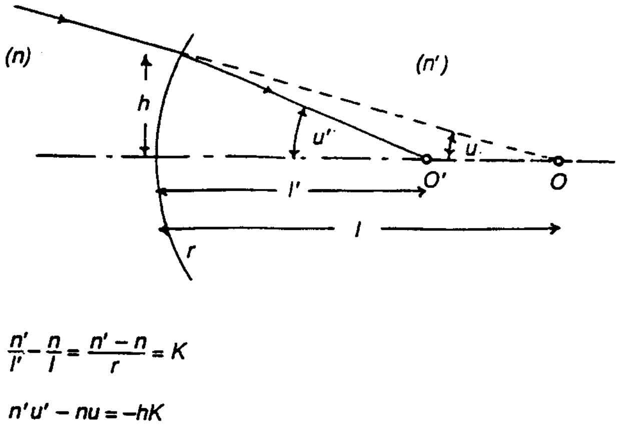
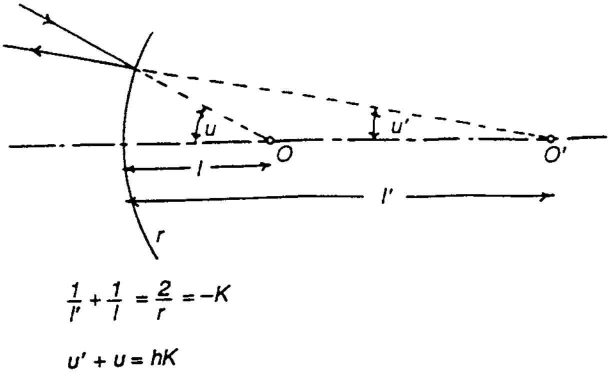


$$\frac{n'}{l'} - \frac{n}{l} = \frac{n' - n}{r} = K$$

$$n'u' - nu = -hK$$

FIGURE 20.5.7



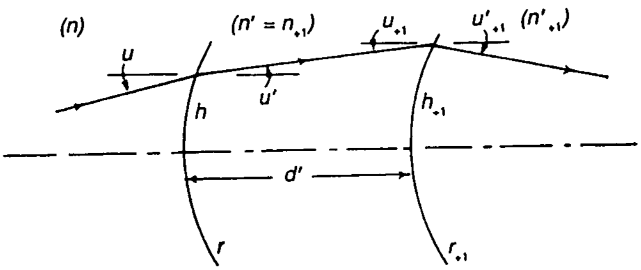
$$\frac{1}{l'} + \frac{1}{l} = \frac{2}{r} = -K$$

$$u' + u = hK$$

FIGURE 20.5.8

The above discussion covers all general Gaussian optic properties of symmetrical optical systems. We next look at particular systems in detail. To do this, we abandon the skeleton representation of the system by its principal planes and foci and consider it as made up of individual refracting or reflecting surfaces.

Figure 20.5.7 and Figure 20.5.8 show the basic properties of a single spherical refracting surface of radius of curvature *r* and of a spherical mirror. In each case *r* as drawn is positive. These diagrams suggest that the properties of more complex systems consisting of more than one surface can be found by tracing paraxial rays rather than by finding the principal planes and foci, and this is what is done in practice. Figure 20.5.9 shows this with an iterative scheme outlined in terms of the convergence angles. The results can then be used to calculate the positions of the principal planes and foci and as the basis of aberration calculations. For details see Welford (1986). The actual convergence angles which can be admitted, as distinguished from notional paraxial angles, are determined either by the rims of individual components or by stops deliberately inserted at places along the axis chosen on the basis of aberration theory. Figure 20.5.10 shows an *aperture stop* in an intermediate space of a system. The components of the system to the left of the stop from an image (generally virtual) which is "seen" from the object position (this image is usually virtual, i.e., it is not physically accessible to be caught on a ground-glass screen like the image in an ordinary looking glass); this image is called the entrance pupil, and it limits the angle of beams that can be taken in from the object. Similarly, on the image side there is an exit pupil, the image of the stop by the components to the right, again usually virtual. This pupil may also determine the angles of beams from off-axis object point *O* and *O*′; the central ray of the beam from *O* passes through the center of the entrance pupil (and therefore through the center of the aperture stop and the center of the exit



$$n'u' - nu = -hK$$
$$u_{+1} = u'$$
$$h_{+1} = h + d'u'$$
$$n'_{+1}u'_{+1} - n_{+1}u_{+1} = -h_{+1}K_{+1}$$

FIGURE 20.5.9

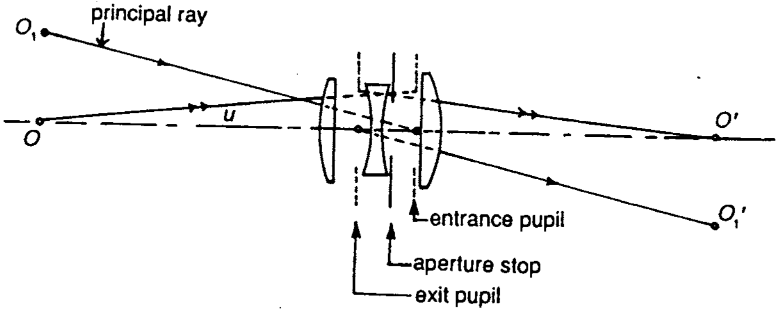


FIGURE 20.5.10

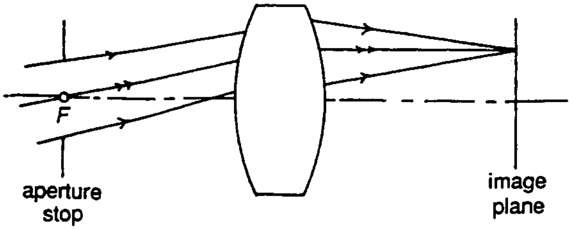

FIGURE 20.5.11

pupil) and it is usually called the *principal*, *chief*, or *reference ray* from this object point. The rest of the beam or pencil from O may be bounded by the rim of the entrance pupil, or it may happen that part of it is *vignetted* by the rim of one of the components.

Although the aperture stop is usually thought of as being inside an optical system, as in a photographic objective, it is sometimes placed outside, and one example is the *telecentric stop* shown in Figure 20.5.11. The stop is at the object-side principal focus, with the result that in the image space all the principal rays emerge parallel to the optical axis. A telecentric stop can be at either the object-side or the image-side principal focus, and the image conjugates can be anywhere along the axis. The effect is that the pupil on the opposite side of the telecentric stop is at infinity, a useful arrangement for many purposes. It may happen that the telecentric stop is between some of the components of the system.

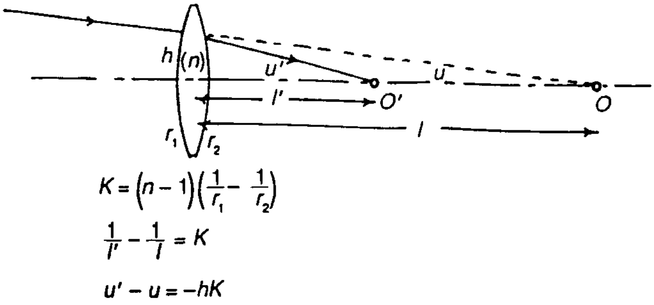

FIGURE 20.5.12

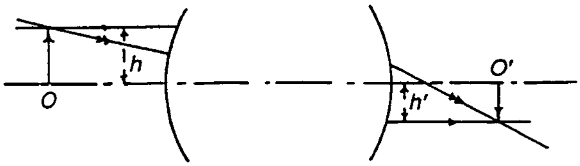

FIGURE 20.5.13

The above information is all that is needed to determine how a given symmetrical optical system behaves in Gaussian approximation for any chosen object plane. Suitable groups of rays can be used to set out the system for mechanical mounting, clearances, etc.; however, it is often easier and adequate in terms of performance to work with the *thin-lens model* of Gaussian optics. This model uses complete lenses of negligible thickness instead of individual surfaces. Figure 20.5.12 shows the properties of a thin lens. A system of thin lenses can be ray traced to find its properties, locate foci and ray clearances, etc., and very often the results will be good enough to use without further refinement. This is particularly true of systems involving unexpanded laser beams, where the beam diameters are quite small.

We omitted from our discussion of Figure 20.5.4 the special case in which a ray incident parallel to the optical axis emerges parallel to the axis, as in Figure 20.5.13. This is an *afocal* or *telescopic* system; it forms an image at infinity of an object at infinity, and the angular magnification is given by the ratio of the ray incidence heights. An afocal system also forms images of objects at finite distances, as indicated by the rays drawn in the figure. The transverse magnification is then constant for all pairs of conjugates.

Plane Mirrors and Prisms

A single-plane mirror used to deflect or rotate an optical axis needs no explanation, but some useful points can be made about combinations of mirrors. Two mirrors at an angle θ turn the beam through 2θ about the line of intersection of the mirror planes, whatever the angle of incidence on the first mirror, as in Figure 20.5.14. The diagram is drawn for a ray in the plane perpendicular to the line of intersection of the mirror planes, but it is equally valid if the ray is not in this plane, i.e., the diagram is a true projection. In particular, if the mirrors are at right angles, as in Figure 20.5.15, the direction of the ray is reversed in the plane of the diagram. Three plane mirrors at right angles to each other, forming a corner of a cube as in Figure 20.5.16, reverse the direction of a ray incident in *any* direction if the ray meets all three mirrors in any order.

These properties are more often used in prisms in the corresponding geometry. Total internal reflection, as in, for example, the right-angle prism (Figure 20.5.17), is a great advantage in using prisms for turning beams. The condition for total internal reflection is

$$\sin I > 1/n \qquad (20.5.10)$$

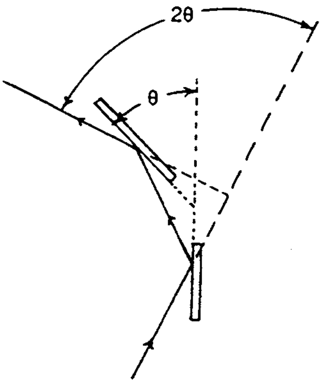

FIGURE 20.5.14

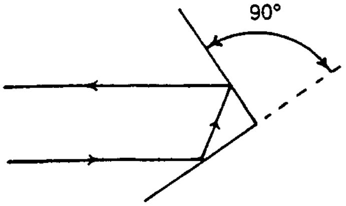

FIGURE 20.5.15

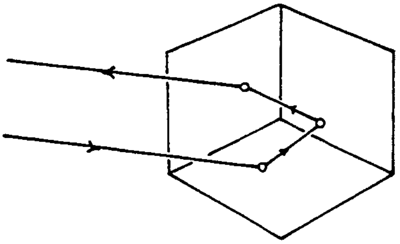

FIGURE 20.5.16

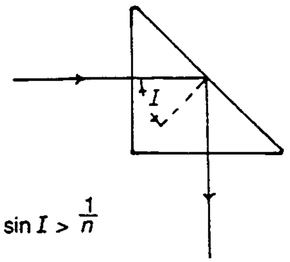

FIGURE 20.5.17

The *critical angle* given by sin$I$ = 1/n is less than 45° for all optical glasses, and probably for all transparent solids in the visible spectrum. Total internal reflection is 100% efficient provided the reflecting surface is clean and free from defects, whereas it is difficult to get a metallized mirror surface that is better than about 92% efficient. Thus, with good anti-reflection coating on the input and output surfaces a prism, such as that shown in Figure 20.5.17, transmits more light than a mirror.

Roof prisms and cube-corner prisms, the analogs of Figure 20.5.15 and 20.5.16, have many uses. The angle tolerances for the right angles can be very tight. For example, roof edges form part of the reversing prism system in some modern binoculars, and an error ε in the right angle causes an image doubling in

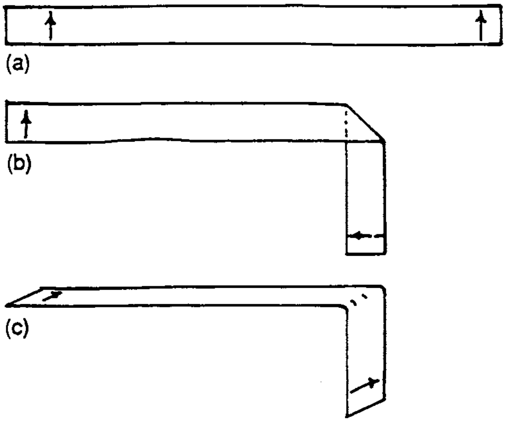

FIGURE 20.5.18

angle of $4n\varepsilon$. The two images are those formed by the portions of the beam incident at either of the two surfaces, which should have been at exactly 90°.

In addition to turning the axis of a system, mirror and prism assemblies sometimes rotate the image in unexpected ways. The effect can be anticipated by tracing, say, three rays from a notional object such as the letter F (i.e., an object with no symmetry). A more direct and graphic method is to use a strip of card and mark arrows on each end as in Figure 20.5.18a. The card is then folded without distorting it as in Figure 20.5.18b to represent, say, reflection at the hypotenuse of the right-angle prism, and the arrows show the image rotation. The process is repeated in the other section, as in Figure 20.5.18c. Provided the folding is done carefully, without distortion, this procedure gives all image rotations accurately for any number of successive reflections.

The Dove prism (Figure 20.5.19) is an example of an image-rotating prism. When the prism is turned through an angle ϕ about the direction of the incident light, the image turns in the same direction through 2ϕ. A more elaborate prism with the same function is shown in Figure 20.5.20. The air gap indicated between the hypotenuses of the two component parts needs to be only about 10 µm or so thick to ensure total internal reflection. Any prism or mirror assembly like this with an odd number of reflections will serve as an image rotator. Figure 20.5.20 illustrates an elegant advantage of prisms over mirrors; the system can be made compact by using the same optical surface both for reflection and for transmission.

Figure 20.5.21 shows a typical beam-splitting (or combining) prism, a component of many diverse optical systems. The beam-splitting surface may be approximately neutral, in which case it would be a thin metal layer, or it may be dichroic (reflecting part of the spectrum and transmitting the rest), or it

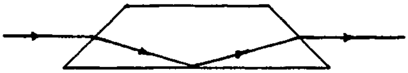

FIGURE 20.5.19

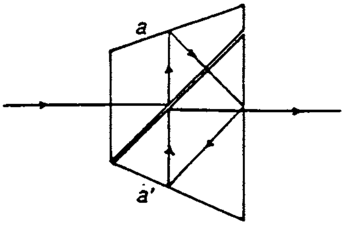

FIGURE 20.5.20

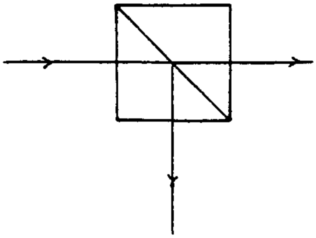

FIGURE 20.5.21

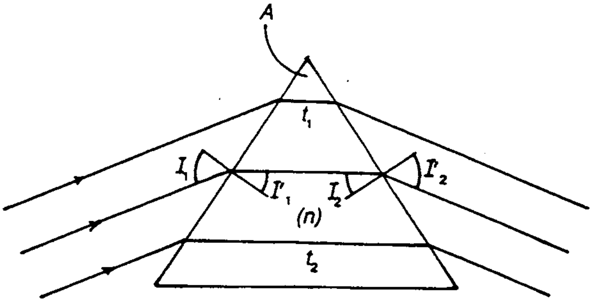

FIGURE 20.5.22

may be polarizing (transmitting the p-polarization and reflecting the s-polarization of a certain wavelength range). In the last two cases the reflecting-transmitting surface is a dielectric multilayer and its performance is fairly sensitive to the angle of incidence.

Prisms as devices for producing a spectrum have been largely replaced by diffraction grating (See Figure 20.5.22). The latter have several advantages for direct spectroscopy, but here are a few specialized areas where prisms are better. Losses in grating through diffraction to unwanted orders are a nuisance in certain astronomical applications where every photon counts. Another example of an area where prisms are preferable is wavelength selection in multiwavelength lasers: a prism inside the laser resonator with adequate angular dispersion ensures that only one wavelength will be produced, and one scans through the available wavelengths by rotating the prisms at and away from the position of minimum deviation. The significance of the minimum deviation position is that the effects of vibrations and placement errors are least. Also, if the shape of the prism is isosceles, the resolving power will be a maximum at minimum deviation. The main formulas relating to dispersing prisms are as follows.

Spectroscopic resolving power:

$$\lambda/\Delta\lambda = (t_1 - t_2)\, dn/d\lambda \tag{20.5.11}$$

where $t_1 - t_2$ is the difference between the path lengths in glass from one side of the beam to the other.

Angular dispersion:

$$dI'_2/d\lambda = \sin A(dn/d\lambda)/(\cos I'_1 \cos I'_2) \tag{20.5.12}$$

$$= 2\sin(A/2)(dn/d\lambda)/\cos I_2 \tag{20.5.13}$$

at minimum deviation.

Spectrum line curvature:

$$1/\text{radius} = \left[(n^2 - 1)/nf\right]\sin A/(\cos I'_1 \cos I'_2) \tag{20.5.14}$$

$$= \left[\left(n^2 - 1\right)/n^2 f\right] 2 \tan I_1 \tag{20.5.15}$$

at minimum deviation, where f is the focal length of the lens which brings the spectrum to a focus.

The spectrum line curvature refers to the observation that the image of the entrance slit of the spectroscope produced by placing a lens after the prism is actually parabolic. The parabola is convex toward the longer wavelengths. The reason the image is curved is that rays out of the principal plane of the prism are deviated more than rays in the plane, a straightforward consequence of the application of Snell's law. For rays with angle out of the plane the extra deviation can be parametrized by an additional contribution to the index of refraction given by

$$dn \approx \varepsilon^2 \left(n^2 - 1\right)(2n) \tag{20.5.16}$$

If the length of the slit image is L, then $\varepsilon \approx L/(2f)$, where f is the focal length of the lens. Moreover, from Equation (20.5.12) we have

$$dI_2'/dn = \sin A / \left(\cos I_1' \cos I_2'\right) \tag{20.5.17}$$

$$= (2/n) \tan I_1 \tag{20.5.18}$$

at minimum deviation. The curvature of the slit image readily follows from these relations.

The typical dispersing prism of constant deviation shown in Figure 20.5.23 has the property that, if it is placed in a collimated beam, the wavelength which emerges at right angles to the incident beam is always at minimum deviation so that the spectrum is scanned by rotating the prism about a suitable axis such as the one indicated.

A prism used a long way from minimum deviation will expand or contract a collimated beam in one dimension. Figure 20.5.24 shows a pair of prisms used in this way to turn a laser beam of elliptical profile (from a diode laser) into a beam of circular profile by expanding it in the plane of the diagram only.

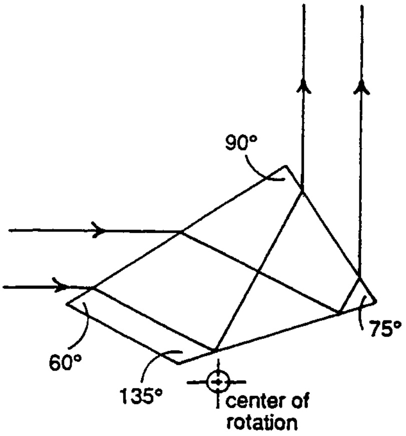

FIGURE 20.5.23

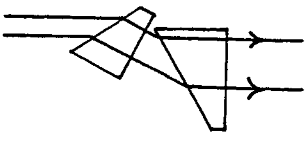

FIGURE 20.5.24

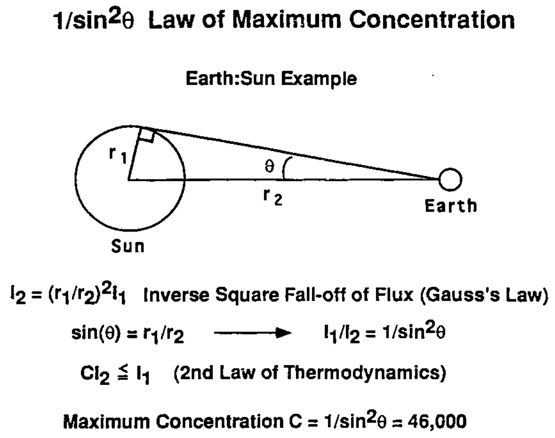

FIGURE 20.5.25

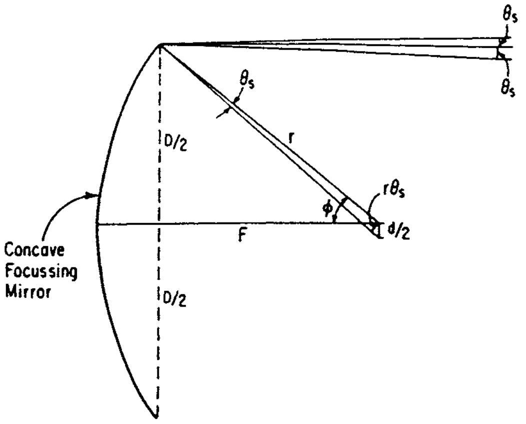

FIGURE 20.5.26

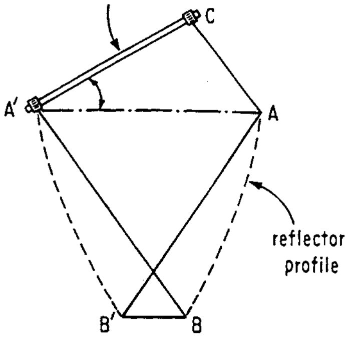
Nonimaging Optics

In one important respect conventional *image-forming* optical design is quite inefficient, that is, in merely concentrating and collecting light. This is well illustrated by an example taken from solar energy concentration (Figure 20.5.25). The flux at the surface of the sun (≈63 W/mm^2) falls off inversely with the square of the distance to a value ≈1.37 mW/mm^2 above the Earth's atmosphere or typically 0.8 to 1 mW/mm^2 on the ground. The second law of thermodynamics permits an optical device (*in principle*) to concentrate the dilute solar flux at Earth so as to attain temperatures up to but not exceeding that of the sun's surface. This places an upper limit on the solar flux density achievable on Earth and correspondingly on the concentration ratio of any optical device. From simple geometry, this limiting concentration ratio is related to the sun's angular size (2θ) by $C_{max} = 1/\sin^2\theta \approx 1/\theta^2$ (small angle approximation). We will call this thermodynamic limit the *sine law of concentration*. Therefore, since $\theta = 0.27°$ or 4.67 mrad, $C_{max} \approx 46{,}000$. When the target is immersed in a medium of refractive index n, this limit is increased by a factor n^2, $C_{max} = n^2/\sin^2\theta$. This means that a concentration of about 100,000 will be the upper limit for ordinary ($n \approx 1.5$) refractive materials. In experiments at the University of Chicago we actually achieved a solar concentration of 84,000 by using a nonimaging design with a refractive medium (sapphire). We would not even have come close using conventional designs, not for any fundamental reason but because imaging optical design is quite inefficient for delivering maximum concentration. For example, consider the paraboloidal mirror of a telescope used to concentrate sunlight at its focus (Figure 20.5.26). We can relate the concentration ratio to the angle 2ϕ subtended by the paraboloid at its focus and the sun's angular size ($2\theta_s$), $C = (\sin\phi\cos\phi/\theta_s)^2 = (^1/_4)\,\sin^2 2\phi/\theta_s^2$, where we have used the small angle approximation for θ_s. Notice that C is maximized at $\phi = \pi/4$, or $C = 1/(4\theta_s^2) = (^1/_4)\,C_{\max}$. In fact, this result does not depend on the detailed shape of the paraboloid and would hold for any focusing mirror. One fares no better (and probably worse) with a lens (a refracting telescope), since the optimum paraboloid in the above example is equivalent in concentrating performance to a lens with focal ratio $f = 1$ which has been corrected for spherical aberration and coma. Such high-aperture lenses are typically complex structures with many components. The thermodynamic limit would require a lens with focal ratio $f = 0.5$ which, as every optical designer knows, is unattainable. The reason for this large shortfall is not hard to find. The paraboloid images perfectly on-axis, but has severe off-axis aberration (coma) which produces substantial image blurring and broadening. Nonimaging optics began in the mid 1960s with the discovery that optical systems could be designed and built that approached the theoretical limit of light collection (the sine law of concentration). The essential point is that requiring an image is unnecessarily restrictive when only concentration is desired. Recognition of this restriction and relaxation of the associated constraints led to the development of nonimaging optics. A nonimaging concentrator is essentially a "funnel" for light. Nonimaging optics departs from the methods of traditional optical design to develop instead techniques for maximizing the collecting power of concentrating elements and systems. Nonimaging designs exceed the concentration attainable with focusing techniques by factors of four or more and approach the theoretical limit (ideal concentrators). The key is simply to dispense with image-forming requirements in applications where no image is required.

Since its inception, the field has undergone three periods of rapid conceptual development. In the 1970s the "string" (see Figure 20.5.27 and Figure 20.5.28) or "edge-ray" method (see Welford and Winston, 1989) was formulated and elaborated for a large variety of geometries. This development was driven by the desire to design wide-angle solar concentrators. It may be succinctly characterized as $\int n\,dl$ = constant along a string. (Notice that replacing "string" by "ray," Fermat's principle, gives all of imaging optics.) In the early 1980s, a second class of algorithms was found, driven by the desire to obtain ideally perfect solutions in three dimensions (3D) (The "string" solutions are ideal only in 2D, and as figures of revolution in 3D are only approximately ideal, though still very useful.) This places reflectors along the lines of flow of a radiation field set up by a radiating lambertian source. In cases of high symmetry such as a sphere or disk, one obtains ideal solutions in *both* 2D and 3D. The third period of rapid development has taken



$$\int_W^{B'} n\,dl = \text{Constant.}\ AC + AB' = A'B + BB'$$
$$AC = AA'\sin\theta$$
$$AB' = A'B$$
$$\Rightarrow AA'\sin\theta = BB'$$

FIGURE 20.5.27

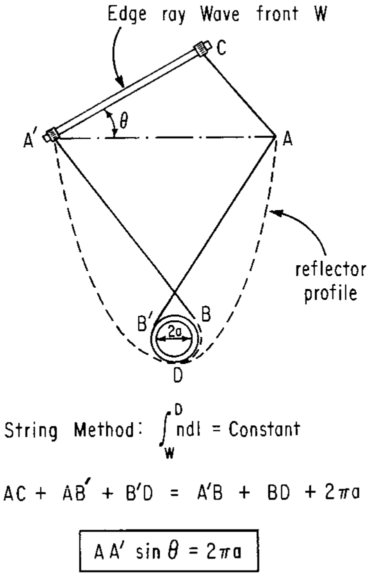


FIGURE 20.5.28

place only in the past several years; its implications and consequences are still in the process of being worked out. This was driven by the desire to address a wider class of problems in illumination that could not be solved by the old methods, for example, uniformly illuminating a plane (e.g., a table or a wall) by a lambertian light source (e.g., a fluorescent light). It is well known that the far-field illuminance from a lambertian source falls off with a power of the cosine of the radiating angle θ. For example, cylindrical radiators (such as a fluorescent lamp) produce a $\cos^2\theta$ illuminance on a distant plane, strip radiators produce a $\cos^3\theta$ illuminance, while circular disk radiators produce a $\cos^4\theta$ illuminance. But suppose one desires a predetermined far-field illuminance pattern, e.g., uniform illuminance? The old designs will not suffice; they simply transform a lambertian source radiating over 2π into a lambertian source radiating over a restricted set of angles. The limitation of the old designs is that they are too static and depend on a few parameters, such as the area of the beam A_1 and the divergence angle θ. One needs to introduce additional degrees of freedom into the nonimaging designs to solve a wider class of problems.

Edge-Ray Optics

One way to design nonimaging concentrators is to reflect the extreme input rays into the extreme output rays. We call this the "edge-ray method." An intuitive realization of this method is to wrap a string about both the light source and the light receiver, then allow the string to unwrap from the source and wrap around the receiver. In introducing the string picture, we follow an insight of Hoyt Hottel (Massachusetts Institute of Technology), who discovered many years ago that the use of strings tremendously simplified the calculation of radiative energy transfer between surfaces in a furnace. Our string is actually a "smart" string; it measures the optical path length (ordinary length times the index of refraction) and refracts in accordance with Snell's law at the interface between different refracting materials. $\int n\,dl$ = constant. The locus traced out turns out to be the correct reflecting surface! Let's see how this works in the simplest kind of problem nonimaging optics addresses: collecting light over an entrance aperture AA' with angular divergence ±θ and concentrating the light onto an exit aperture BB' (Figure 20.5.27). We attach one end of the string to the edge of the exit aperture *B* and the loop at the other end over a line WW' inclined at angle θ to the entrance aperture (this is the same as attaching to a "point at infinity"). We now unwrap the string and trace out the locus of the reflector taking care that string is taut and perpendicular to WW'. Then we trace the locus of the other side of the reflector. We can see with a little algebra that when we are done the condition for maximum concentration has been met. When we start unwrapping the

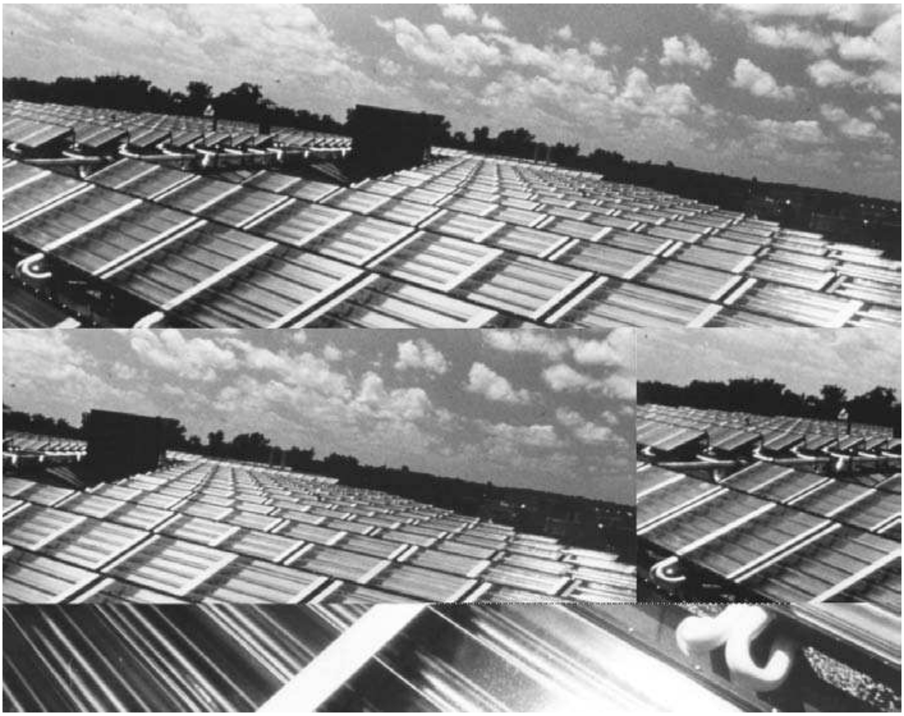

FIGURE 20.5.29

string, the length is $AB' + BB'$; when we finish, the same length is $WA' + A'B$. But $WA' = AA'\sin\theta$, while $AB' = A'B$. So we have achieved $AA'/BB' = 1/\sin\theta$ which is maximum concentration! To see why this works, we notice that the reflector directs all rays at ±θ to the edges BB' so that rays at angles $> \pm\theta$ are reflected out of the system and rejected. Now there is a conservation theorem for light rays called conservation of phase space or "etendue" which implies that if the rays at angles $> \pm\theta$ are rejected, then the rays that have angles $<\theta$ are all collected. Next we can try a more-challenging problem, where the "exit aperture" is a cylinder of radius a (Figure 20.5.28). Now we attach the string to a point on the cylinder and wrap it around the cylinder. When the string is unwrapped, we find that $AA'/2\pi a = 1/\sin\theta$ which is maximum concentration on the surface of the cylinder! Such designs are useful for solar-thermal concentrators since the typical receiver is a tube for carrying fluid. A solar plant for powering air conditioners that uses this design is shown in Figure 20.5.29. As already mentioned, there is an alternative method for designing "ideal" optical systems which bears little resemblance to the "string method" already described. We picture the aggregate of light rays traversing an optical system as a fluid flow in an abstract space called phase space.This is the "space" of ray positions and ray directions multiplied by the index of refraction, so it has twice the number of dimensions of ordinary space. By placing reflectors along the lines of flow of this vector field, nonimaging designs are generated. Flow-line designs are perfect in three dimensions, while the string designs rotated about an axis are not. On the other hand, the number of flow-line designs are much more restricted. For details see Welford and Winston (1989).

Lasers

Lasers are by now a ubiquitous light source with certain properties in addition to coherence and monochromaticity which have to be taken account of in some applications. Aside from many research applications of lasers, the HeNe laser at 632.8 nm wavelength has been available for several decades for alignment, surveying, and the like. But the explosive uses of lasers have come only recently with the advent of the solid-state diode laser. To appreciate the convenience of diode lasers one can draw upon the analogy between transistors and vacuum tubes. Inexpensive diode lasers are in widespread use in compact disk players, optical disk readers, and fiber-optics communications. The list of consumer applications is growing rapidly (e.g., laser pointers). In addition, diode lasers are used in arrays to optically drive (pump) more powerful lasers. The radiation that lasers emit can be highly coherent, and, except for the wavelength, of the same general character as the radiation from a radio frequency oscillator. We can identify four elements common to nearly all lasers (we follow the discussion in Mandel and Wolf, 1995, which should be consulted for details):

1. An optical resonator, generally formed by two or more mirrors;
2. A gain medium in which an inverted atomic population between the laser energy levels is established;
3. An optical pump or energy source to excite the gain medium;
4. A loss mechanism by which energy is dissipated or dispersed.

Figure 20.5.30 shows a typical form of laser, in which the resonator is a Fabry–Perot interferometer, and the amplifier is a gas plasma tube wherein a discharge is maintained. To reduce reflection losses from the plasma tube, its end windows are generally arranged at the Brewster angle for linearly polarized light at the laser frequency. The end mirrors are usually provided with multilayer dielectric coatings to make them highly reflecting. Of course, the output mirror needs to have its reflectivity, R, less than 100%, so that $(1 - R)$ is commonly the main source of the energy loss that has to be compensated by the gain medium. The cavity mirrors play the important role of feeding photons belonging to the laser modes back into the laser cavity. Most of the spontaneously emitted photons traveling in various other directions are lost. However, photons associated with a cavity resonance mode interact repeatedly with the atoms of the gain medium, and their number grows through stimulated emission, as illustrated in Figure 20.5.31. Once one mode is sufficiently populated, the probability for stimulated emission into that mode exceeds the spontaneous emission probability. In general, when the rate at which photons are fed into the optical cavity mode exceeds the rate at which they are lost from the cavity by the loss mechanism, the amplitude of the laser field starts to grow until a steady state is reached. At that point the rate of radiation by the laser equals the net rate at which energy is supplied. It is easy to see that this is achievable by an inverted population between the two atomic laser levels, with more atoms in the upper laser state than in the lower. If N_2, N_1 are the upper state and lower state populations, the rate of absorption of laser photons by the atomic system is proportional to N_1, and the rate of stimulated emission of laser photons by the system is proportional to N_2, with the same constant of proportionality for both. If N_2 exceeds N_1 sufficiently, all the radiation losses can be made good by the atomic system. It can be shown that the condition for laser action (in a single mode) is

$$N_2 - N_1 > 2A(1 - R)/\lambda^2 \tag{20.5.19}$$

where A is the cross-sectional area of the laser and λ is the wavelength.

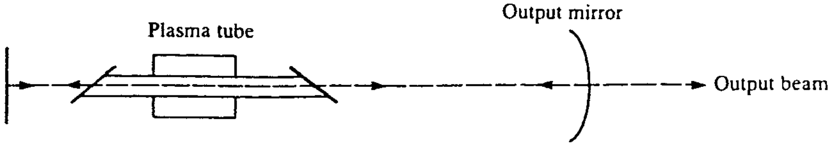

FIGURE 20.5.30 A simple form of laser.

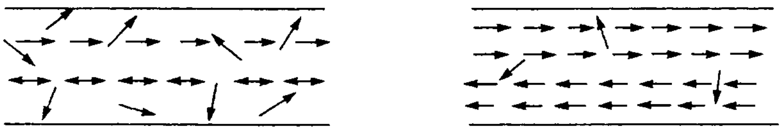

FIGURE 20.5.31 Illustration of the growth of the stimulated emission probability with the intensity of the mode.

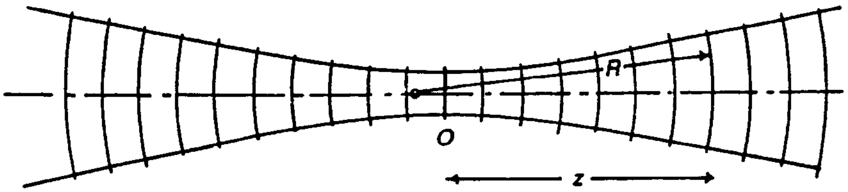

FIGURE 20.5.32

We next summarize how the special properties of laser beams are to be taken into account in optical design. The well-known Gaussian intensity profile of laser beams persists if it is taken through a sequence of lenses along the axis, and at certain points that can be more-or-less predicted by paraxial optics a "focus" is formed. But when, as often happens, the convergence angle in the space in which this occurs is small, say, 1 mrad or less, some departures from the predictions of the paraxial optics occur. We shall examine these effects, since they are of importance in many of the systems already mentioned.

Gaussian Beams

In paraxial approximation the simplest form of a single-mode beam is the TEM_{00} Gaussian beam shown in Figure 20.5.32. Starting from the narrowest part, known as the waist, the beam diverges with spherical phase fronts. The complex amplitude at the waist has the form

$$A = A_0 \exp\left(-r^2/\omega_0^2\right) \tag{20.5.20}$$

where ω_0 is called the beam width and r is a radial coordinate.

At a distance z along the beam in either direction, the complex amplitude is, apart from a phase factor,

$$A = \left(\omega_0/\omega\right) A_0 \exp\left(-r^2/\omega_0^2\right) \tag{20.5.21}$$

where ω is given by

$$\omega(z) = \omega_0\left[1 + \left(\lambda z/\pi\omega_0^2\right)\right]^{1/2} \tag{20.5.22}$$

At a distance z from the waist, the phase fronts have a radius of curvature R given by

$$R(z) = z\left[1 + \left(\pi\omega_0^2/\lambda z\right)^2\right] \tag{20.5.23}$$

The beam contour of constant intensity A_0^2/e^2 is a hyperboloidal surface of (small) asymptotic angle given by

$$\theta = \lambda/\pi\omega_0 \tag{20.5.24}$$

It can be seen that the centers of curvature of the phase fronts are not at the beam waist; in fact the phase front is plane at that point. The geometrical wavefronts are not exactly the same as true phase fronts, and if in this case we postulate that geometrical wavefronts should have their centers of curvature at the beam waist, we have an example of this. However, the difference is small unless the convergence angle is very small or, more precisely, when the Fresnel number of the beam is not much larger than unity:

$$\text{Fresnel number } = \omega^2/\lambda R \tag{20.5.25}$$

There is nothing special about Gaussian beams to cause this discrepancy between phase fronts and geometrical wavefronts; a similar phenomenon occurs with beams which are sharply truncated by the pupil ("hard-edged" beams). But it happens that it is less usual to be concerned with the region near the focus of a hard-edged beam of small Fresnel number, whereas Gaussian beams are frequently used in this way. Thus, Born and Wolf, *Principles of Optics* (1999) show that the phase front at the focus of a hard-edged beam is also plane, but with rapid changes of intensity and phase jumps across the zeros of intensity.

Tracing Gaussian Beams

If the beam is in a space of large convergence angle, say, greater than 10 mrad, it can be traced by ordinary paraxial optics, i.e., using the assumption that for all practical purposes the phase fronts are the same as geometrical wavefronts. In a space of small convergence angle it is necessary to propagate the beam between refracting surfaces by means of the proper Gaussian beam formulas and then use paraxial optics to refract (or reflect) the phase front through each surface in turn. To do this, we need two more formulas to give the position, z, and size of the beam waist starting from the beam size and phase front curvature at an arbitrary position on the axis, i.e., given ω and R. These are

$$z = R\left[1 + \left(\lambda z/\pi\omega^2\right)\right]^{-1} \tag{20.5.26}$$

and

$$\omega_0 = \omega\left[1 + \left(\pi\omega^2/\lambda R\right)^2\right]^{-1/2} \tag{20.5.27}$$

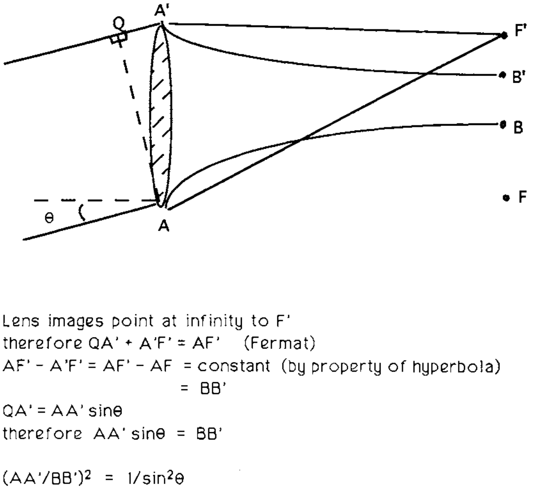
Equation (20.5.22) to Equation (20.5.27) enable a Gaussian beam to be traced through a sequence of refracting surfaces as an iterative process. Thus, starting from a beam waist of given size ω_0 (and angle given by Equation (20.5.24)), we move a distance z to the first refracting surface. At this surface the beam size ω is given by Equation (20.5.22) and the radius of curvature R of the phase front is given by Equation (20.5.23). The radius of curvature R' of the refracted phase front is obtained by paraxial optics using the equation of Figure 20.5.7 and taking R and R' as the conjugate distances l and l'. Then the position and size of the new beam waist are found from Equation (20.5.26) and Equation (20.5.27). These procedures can be carried through all the refracting surfaces of the optical system.

It can be seen from Equation (20.5.26) that z and R are substantially equal when $\lambda R/\pi\omega^2$ is very small. When this is so, there is no need to use these special equations for transferring between surfaces; the iterative equations in Figure 20.5.9 can be used, with the understanding that the paraxial convergence angle u is the equivalent of the asymptotic angle θ in Equation (20.5.24).

There are no simple equations for hard-edged beams corresponding to Equation (20.5.23) to Equation (20.5.27) for use with very small convergence angles. Numerical calculations of the beam patterns near focus have been published for some special cases, and these show, as might be expected, very complex structures near the "focal" region; however, that is defined.

Truncation of Gaussian Beams

The theoretical origin of the Gaussian beam is as a paraxial solution of the Helmholtz equation, i.e., a solution concentrated near one straight line, the axis, but although most of the power is within the region near the axis the solution is nonzero, although very small, at an infinite distance from the axis. Thus, the Gaussian profile is truncated when it passes through any aperture of finite diameter — e.g., a lens mount, an aperture stop, or even the finite-diameter end mirror of a laser resonator — after which it is no longer Gaussian and the above equations are no longer valid! In practice, this need not be a problem, for if the radius of the aperture is 2ω, the complex amplitude is down to 1.8% of its value at the center



Lens images point at infinity to F'
therefore QA' + A'F' = AF' (Fermat)
AF' − A'F' = AF' − AF = constant (by property of hyperbola)
= BB'
QA' = AA' sinθ
therefore AA' sinθ = BB'

$(AA'/BB')^2 = 1/\sin^2\theta$

FIGURE 20.5.33

and the intensity is 0.03% of its value at the center. Thus, it is often assumed that an aperture of radius 2ω has no significant effect on the Gaussian beam, and this assumption is adequate for many purposes, although not all.

Sometimes it is useful to truncate a Gaussian beam deliberately, i.e., turn it into a hard-edged beam, by using an aperture of radius less than, say, ω. In this way an approximation to the Airy pattern is produced at the focus instead of a Gaussian profile waist, and this pattern may be better for certain purposes, e.g., for printers where the spot must be as small as possible for an optical system of given numerical aperture.

Gaussian Beams and Aberrations

In principle, a Gaussian beam is a paraxial beam, from the nature of the approximations made in solving the Helmholtz equation. However, Gaussian beams can be expanded to large diameters simply by letting them propagate a large distance, and they can acquire aberrations by passing through an aberrating lens or mirror system. The beam is then no longer Gaussian, of course, in the strict sense, but we stress that the conventional optical design idea involving balancing and reduction of aberrations can be applied to systems in which Gaussian beams are to propagate. For example, a *beam expander*, of which one form in shown in Figure 20.5.33, is an afocal system intended to do what its name implies: if it has aberrations as an afocal system, the output beam from a Gaussian input beam will not have truly plane or spherical phase fronts.

Non-Gaussian Beams from Lasers

Not all lasers produce Gaussian beams, even ignoring the inevitable truncation effects of resonator mirrors. Some gas lasers (e.g., helium-neon at any of its lasing wavelengths) produce Gaussian beams when they are in appropriate adjustment, but they can produce off-axis modes with more structure than a Gaussian beam. Other gas lasers (e.g., copper vapor lasers) produce beams with a great many transverse modes covering an angular range of a few milliradians in an output beam perhaps 20 mm across. Some solid-state lasers, e.g., ruby, may produce a very non-Gaussian beam because of optical inhomogeneities in the ruby. Laser diodes, which as already mentioned are becoming increasingly useful as very compact coherent sources, whether cw or pulsed, produce a single strongly divergent transverse mode which is wider across one direction than the other. This mode can be converted into a circular section of approximately Gaussian profile by means of a prism system, as in Figure 20.5.24.

20.6 Water Desalination

Noam Lior

Introduction and Overview

Water desalination is a process that separates water from a saline water solution. The natural water cycle is the best and most prevalent example of water desalination. Ocean waters evaporate due to solar heating and atmospheric influences; the vapor consisting mostly of fresh water (because of the negligible volatility of the salts at these temperatures) rises buoyantly and condenses into clouds in the cooler atmospheric regions, is transported across the sky by cloud motion, and is eventually deposited back on the earth surface as fresh water rain, snow, and hail. The global freshwater supply from this natural cycle is ample, but many regions on Earth do not receive an adequate share. Population growth, rapidly increasing demand for fresh water, and increasing contamination of the available natural fresh water resources render water desalination increasingly attractive. Water desalinaiton has grown over the last four decades to an output of about 20 million m^3 of fresh water per day, by about 10,000 sizeable land-based water desalination plants.

The salt concentration in the waters being desalted ranges from below 100 ppm wt. (essentially fresh water, when ultrapure water is needed), through several thousand parts per million (brackish waters unsuitable for drinking or agricultural use) and seawater with concentrations between 35,000 and 50,000 ppm. Official salt concentration limits for drinkable water are about 1000 ppm, and characteristic water supplies are restricted to well below 500 ppm, with city water in the United States being typically below 100 ppm. Salinity limits for agricultural irrigation waters depend on the type of plant, cultivation, and soil, but are typically below 2000 ppm.

Many ways are availiable for separating water from a saline water solution. The oldest and still prevalent desalination process is distillation. The evaporation of the solution is effected by the addition of heat or by lowering of its vapor pressure, and condensation of these vapors on a cold surface produces fresh water. The three dominant distillation processes are multistage flash (MSF), multieffect (ME), and vapor compression (VC). Until the early 1980s the MSF process was prevalent for desalination. Now membrane processes, especially reverse osmosis (RO), are economical enough to have taken about one third of the market. In all membrane processes separation occurs due to the selective nature of the permeability of a membrane, which permits, under the influence of an external driving force, the passage of either water or salt ions but not of both. The driving force may be pressure (as in RO), electric potential (as in electrodialysis, ED), or heat (as in membrane distillation, MD). A process used for low-salinity solutions is the well-known ion exchange (IE), in which salt ions are preferentially adsorbed onto a material that has the required selective adsorption property and thus reduce the salinity of the water in the solution.

The cost of desalted water is comprised of the capital cost of the plant, the cost of the energy needed for the process, and the cost of operation and maintenance staff and supplies. In large seawater desalination plants the cost of water is about \$1.4 to \$2/m^3, dropping to less than \$1/m^3 for desalting brackish water. A methodology for assessing the economic viability of desalination in comparison with other water supply methods is described by Kasper and Lior (1979). Desalination plants are relatively simple to operate, and progress toward advanced controls and automation is gradually reducing operation expenses.

The relative effect of the cost of the energy on the cost of the fresh water produced depends on local conditions, and is up to one half of the total.

The boiling point of a salt solution is elevated as the concentration is increased, and the **boiling point elevation** is a measure of the energy needed for separation. Thermodynamically reversible separation defines the minimal energy requirement for that process. The minimal energy of separation $W_{\min}$ in such a process is the change in the Gibbs free energy between the beginning and end of the process, ΔG. The minimal work when the number of moles of the solution changes from n_1 to n_2 is thus

$$W_{\min} = \int_{n_1}^{n_2} (\Delta G)\, dn_W \tag{20.6.1}$$

The minimal energy of separation of water from seawater containing 3.45 wt.% salt, at 25°C, is 2.55 kJ/(kg fresh water) for the case of zero fresh water recovery (infinitesimal concentration change) and 2.91 kJ/(kg fresh water) for the case of 25% freshwater recovery. $W_{\min}$ is, however, severalfold smaller than the energy necessary for water desalination in practice. Improved energy economy can be obtained when desalination plants are integrated with power generation plants (Aschner, 1980). Such dual-purpose plants save energy but also increase the capital cost and complexity of operation.

Two aspects of the basically simple desalination process require special attention. One is the highcorrosivity of seawater, especially pronounced in the higher-temperature destillation processes, which requires the use of corrosion-resistant expensive materials. Typical materials in use are copper–nickel alloys, stainless steel, titanium, and, at lower temperatures, fiber-reinforced polymers (George et al., 1975). Another aspect is scale formation (Glater et al., 1980; Heitman, 1990). Salts in saline water, particularly calcium sulfate, magnesium hydroxide, and calcium carbonate, tend to precipitate when a certain temperature and concentration are exceeded. The precipitate, often mixed with dirt entering with the seawater and with corrosion products, will gradually plug up pipes, and when depositing on heat transfer surfaces reduces heat transfer rates and thus impairs plant performance. While the ambient-temperature operation of membrane processes reduces scaling, membranes are much more susceptible not only to minute amounts of scaling or even dirt, but also to the presence of certain salts and other compounds that reduce their ability to separate salt from water. To reduce corrosion, scaling, and other problems, the water to be desalted is pretreated. The pretreatment consists of filtration, and may inlude removal of air (deaeration), removal of CO_2 (decarbonation), and selective removal of scale-forming salts (softening). It also includes the addition of chemicals that allow operation at higher temperatures without scale deposition, or which retard scale deposition and/or cause the precipitation of scale which does not adhere to solid surfaces, and that prevent foam formation during the desalination process.

Saline waters, including seawater, contain, besides a variety of inorganic salts, also organic materials and various particles. They differ in composition from site to site, and also change with time due to both natural and person-made causes. Design and operation of desalination plants requires good knowledge of the saline water composition and properties (Fabuss, 1980; Heitman, 1991).

The major water desalination processes that are currently in use or in advanced research stages are concisely described below. Information on detailed modeling can be found in the references.

Distillation Processes

Multistage Flash Evaporation (MSF)

Almost all of the large desalination plants use the MSF process shown schematically in Figure 20.6.1. A photo of an operating plant is shown in Figure 20.6.2. The seawater feed is preheated by internal heat recovery from condensing water vapor during passage through a series of stages, and then heated to its top temperature by steam generated by an external heat source. The hot seawater then flows as a horizontal free-surface stream through a series of "stages," created by vertical walls which separate the vapor space of each stage from the others. These walls allow the vapor space of each stage to be maintained at a different pressure, which is gradually decreased along the flow path due to the gradually decreasing

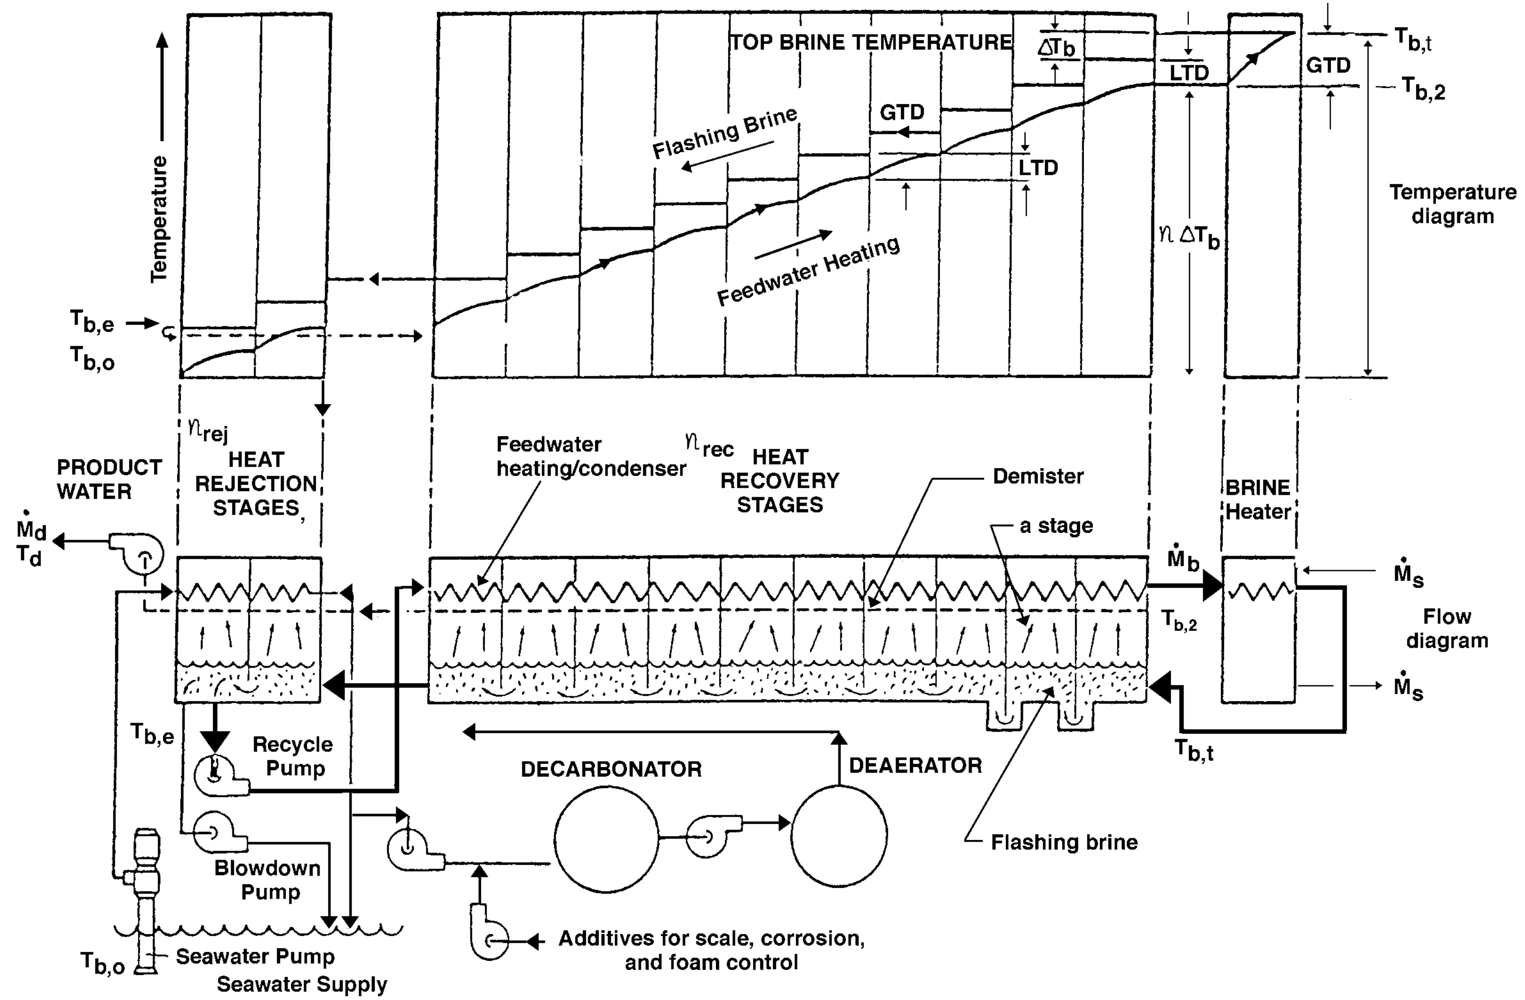

FIGURE 20.6.1 Schematic flow and temperature diagram of the MSF process, for a recirculation type plant.

FIGURE 20.6.2 One of the six units of the 346,000 m^3/day MSF desalination plant Al Taweelah B in Abu Dhabi, United Arab Emirates. (Courtesy of Italimpianti S. p. A.) It is a dual-purpose plant, composed of six identical power and desalination units. Five of the six boilers are seen in the background. The desalination units were in 1996 the largest in the world. They have 17 recovery and 3 reject stages and a performance ratio (PR) of 8.1. The plant also produces 732 MWe of power.

temperature in the condenser/seawater-preheater installed above the free stream. The seawater is superheated by a few degrees celsius relative to the vapor pressure in each stage it enters, and consequently evaporates in each stage along its flow path. The latent heat of the evaporation is supplied by equivalent reduction of the sensible heat of the evaporating water, thus resulting in a gradual lowering of the stream temperature. The evaporation is vigorous, resulting in intensive bubble generation and growth with accompanying stream turbulence, a process known as **flash evaporation** (Lior and Greif, 1980; Miyatake et al., 1992; 1993). One of the primary advantages of the MSF process is the fact that evaporation occurs from the saline water stream and not on heated surfaces (as in other distillation processes such as submerged tube and ME evaporation) where evaporation typically causes scale depostition and thus gradual impairment of heat transfer rates. Also, the fact that the sensible heat of water is much smaller than its latent heat of evaporation, where the specific heat $c_p = 4.182$ kJ/kg/°C change of water temperature and the latent heat is $h_{fg} = 2378$ kJ/kg, and the fact that the top temperature is limited by considerations of scaling and corrosion, dictate the requirement for a very large flow rate of the evaporating stream. For example (in the following, the subscripts *b*, *d*, and *s* refer to brine distillate, and steam, respectively), operating between a typical top temperature $T_{b,t}$ of 90°C at the inlet to the evaporator and an exit temperature $T_{b,e}$ of 40°C corresponding to the ambient conditions, the overall temperature drop of the evaporating stream if 50°C. By using these values, the heat balance between the sensible heat of the water stream, flowing at a mass flow rate $\dot{m}_b$, and the latent heat needed for generating water vapor (distillate) at a mass flow rate $\dot{m}_d$ is

$$\left(\dot{m}_b - \dot{m}_d\right) c_p \left(T_{b,t} - T_{b,e}\right) \approx \dot{m}_d h_{fg} \tag{20.6.2}$$

which yields the brine-to-product mass flow ratio as

$$\frac{\dot{m}_b}{\dot{m}_d} = \frac{h_{fg}}{c_p\left(T_{b,t} - T_{b,e}\right)} + 1 = \frac{2378}{(4.182)(50)} + 1 = 12.37 \tag{20.6.3}$$

Therefore, 12.37 kg of saline water are needed to produce 1 kg of distillate. This high flow rate incurs corresponding pumping equipment and energy expenses, sluggish system dynamics, and, since the stream level depth is limited to about 0.3 to 0.5 m for best evaporation rates, also requires large evaporator vessels with their associated expense.

The generated water vapor rises through a screen ("demister") placed to remove entrained saline water droplets. Rising further, it then condenses on the condenser tube bank, and internal heat recovery is achieved by transferring its heat of condensation to the seawater feed that is thus being preheated. This internal heat recovery is another of the primary advantages of the MSF process. The energy performance of distillation plants is often evaluated by the *performance ratio*, PR, typically defined as

$$\mathrm{PR} \equiv \frac{\dot{m}_d}{\dot{m}_s} \tag{20.6.4}$$

where $\dot{m}_s$ is the mass flow rate of heating steam. Since the latent heat of evaporation is almost the same for the distillate and the heating steam, PR is also the ratio of the heat energy needed for producing one unit mass of product (distillate) to the external heat actually used for that purpose. Most of the heating of the brine stream to the top temperature $T_{b,t}$ is by internal heat recovery, and as seen in Figure 20.6.1, the external heat input is only the amount of heat needed to elevate the temperature of the preheated brine from its exit from the hottest stage at $T_{b,2}$ to $T_{b,t}$. Following the notation in Figure 20.6.1, and using heat balances similar to that in Equation (20.6.3) for the brine heater and flash evaporator, the PR can thus also be defined as

$$\mathrm{PR} = \frac{\dot{m}_b\left(\overline{c_{p,b}}\right)_{e\to t}\left(T_{b,t} - T_{b,e}\right)\Big/h_{fg,b}}{\dot{m}_b\left(\overline{c_{p,b}}\right)_{2\to t}\left(T_{b,t} - T_{b,2}\right)\Big/h_{fg,s}} \approx \frac{T_{b,t} - T_{b,e}}{T_{b,t} - T_{b,2}} \tag{20.6.5}$$

where $(\overline{c_{p,b}})_{e\to t}$ and $(\overline{c_{p,b}})_{2\to t}$ are the specific heats of brine, the first averaged over the temperature range $T_{b,e} \to T_{b,t}$ and the second over $T_{b,2} \to T_{b,t}$. The rightmost expression in Equation (20.6.5) is nearly correct because the specific heat of the brine does not change much with temperature, and the latent heat of evaporation of the brine is nearly equal to the latent heat of condensation of the heating steam. It is obvious from Equation (20.6.5) that PR increases as the top heat recovery temperature $T_{b,2}$ (at the exit from the condenser/brine-preheater) increases. It is also obvious (even from just examining Figure 20.6.1) that increasing the number of stages (matched with a commensurate increase in condenser heat transfer area and assuming no significant change in the overall heat transfer coefficient) for a given $T_{b,t}$, will raise the flash evaporator inlet temperature $T_{b,3}$, which will lead to a rise in $T_{b,2}$ and thus also in the PR.

Assuming that the temperature drop of the flashing brine, ΔT_b, is the same in each stage, the relationship between the number of stages (n) and the performance ratio is

$$\mathrm{PR} = \frac{1}{\dfrac{\mathrm{LTD}}{T_{b,t} - T_{b,e}} + \dfrac{1}{n}} \tag{20.6.6}$$

where LTD is the lowest temperature difference between the flashed vapor and the heated feedwater, in each stage (Figure 20.6.1). Equation (20.6.6) shows that increasing the number of stages increases the PR. This implies that more heat is then recovered internally, which would thus require a larger condenser/brine-preheater heat transfer area. The required heat transfer area, A, *per unit mass of distillate produced* for the entire heat recovery section (composed of n_{rec} stages), and taking average values of the overall vapor-to-feedwater heat transfer coefficient U and LMTD, is thus

$$A = n_{\mathrm{rec}} A_n = n_{\mathrm{rec}} \frac{h_{b,fg}}{U(\mathrm{LMTD})} \tag{20.6.7}$$

LMTD, the log-mean temperature difference between the vapor condensing on the tubes and the heated brine flowing inside the tubes, for an average stage is

$$\text{LMTD} = \frac{\text{GTD} - \text{LTD}}{\ln \dfrac{\text{GTD}}{\text{LTD}}} = \frac{\left(T_{b,t} - T_{b,2}\right) - \text{LTD}}{\ln\left(\dfrac{T_{b,t} - T_{b,2}}{\text{LTD}}\right)} \tag{20.6.8}$$

where GTD is the greatest temperature difference between the flashing brine and the brine heated in the condenser. The size of the heat transfer area per unit mass of distillate is

$$A = \frac{h_{fg,b}}{U} \frac{n_{\text{rec}}}{\left(T_{b,t} - T_{b,e}\right)} \ln\left(\frac{n_{\text{rec}}}{n_{\text{rec}} - PR}\right) \tag{20.6.9}$$

Examination of this equation will show that the required heat transfer area for the heat recovery section per unit mass of distillate produced, A, increases significantly when PR is increased, and decreases slightly as the number of heat recovery stages, n_{rec}, is increased.

The MSF plant shown in Figure 20.6.1 is of the *recirculation* type, where not all of the brine stream emerging from the last evaporation stage is discharged from the plant (as it would have been in a *once-through* type of plant). A fraction of the emerging brine is mixed with pretreated seawater and recirculated into the condenser of the heat recovery section of the plant. Since only a fraction of the entire stream in this configuration is new seawater, which needs to be pretreated (removal of air and CO_2, i.e., deaeration and decarbonation, and the addition of chemicals that reduce scale deposition, corrosion, and foaming), the overall process cost is reduced. The recirculation plant is also easier to control than the once-through type.

While most of the energy exchange in the plant is internal, steady-state operation requires that energy in an amount equal to all external energy input be also discharged from the plant. Consequently, the heat supplied in the brine heater (plus any pumping energy) is discharged in the heat rejection stages section of the plant (Figure 20.6.1). Assuming an equal temperature drop in each stage, and that the pumping energy can be neglected relative to the heat input in the brine heater, indicates that the ratio of the number of the heat-recovery to heat-rejection stages is approximately equal to the performance ratio PR.

Further detail about MSF desalination can be found in Steinbruchel and Rhinesmith, (1980) and Khan (1986). A detailed design of an MSF plant producing 2.5 million gals. of freshwater per day was published by the U.S. government (Burns and Roe, 1969).

Multi-Effect Distillation (ME)

The principle of the ME distillation process is that the latent heat of condensation of the vapor generated in one effect is used to generate vapor in the next effect, thus obtaining internal heat recovery and good energy efficiency. Several ME plant configurations, most prominently the horizontal tube ME (HTME, shown in Figure 20.6.3) and the vertical tube evaporator (VTE, shown schematically in Figure 20.6.4) are in use. In the HTME, vapor is circulated through a horizontal tube bundle, which is subjected to an external spray of somewhat colder saline water. The vapor flowing in these spray-cooled tubes condenses, and the latent heat of condensation is transferred through the tube wall to the saline water spray striking the exterior of the tube, causing it to evaporate. The vapor generated thereby flows into the tubes in the next effect, and the process is repeated from effect to effect.

In the VTE the saline water typically flows downward inside vertical tubes and evaporates as a result of condensation of vapor coming from a higher temperature effect on the tube exterior. While internal heat recovery is a feature common to both MSF and ME processes, there are at least three important differences between them. One is that evaporation in the ME process occurs on the heat transfer surfaces (tubes), while in the MSF process it takes place in the free stream. This makes the ME process much

FIGURE 20.6.3 Two HTME desalination units, each producing 5000 m^3/day, in St. Croix, U.S. Virgin Islands. (Courtesy of I.D.E. Technologies Ltd.)

more susceptible to scale formation. At the same time, the heat transfer coefficient between the vapor and the preheated brine is lower in the MSF process because the heated brine does not boil. In the ME process it does boil, and it is well known that boiling heat transfer coefficients are significantly higher than those where the heating does not result in boiling. In using direct transfer of latent heat of condensation to latent heat of evaporation, instead of sensible heat reduction to latent heat of evaporation as in MSF, the ME process requires a much smaller brine flow than the MSF. Limiting brine concentration in the last effect to about three times that of the entering seawater, for example, requires a brine flow of only about 1.5 times that of the distillate produced. At the same time, a pump (although much smaller than the two pumps needed in MSF) is needed for each effect.

The PR of ME plants is just sightly lower than the number of effects, which is determined as an optimized compromise between energy efficiency and capital cost. Six effects are typical, although plants with as many as 18 effects have been built.

Further detail about ME desalination can be found in Steinbruchel and Rhinesmith (1980) and Standiford, (1986a).

Vapor Compression Distillation (VC)

As stated earlier, the vapor pressure of saline water is lower than that of pure water at the same temperature, with the pressure difference proportional to the boiling point elevation of the saline water. Desalination is attained here by evaporating the saline water and condensing the vapor on the pure water. Therefore, the pressure of the saline water vapor must be raised by the magnitude of that pressure difference, plus some additional amount to compensate for various losses. This is the principle of the vapor compression desalination method. Furthermore, as shown in Figure 20.6.5, the heat of condensation of the compressed vapor is recovered internally by using it to evaporate the saline water. Additional heat recovery is obtained by transferring heat from the concentrated brine effluent and the produced freshwater (which need to be cooled down to as close to ambient conditions as possible anyway) to the feed saline water which is thus preheated. The schematic flow diagram in Figure 20.5.5 shows a design in which the preheated seawater is sprayed onto a bank of horizontal tubes carrying condensing compressed vapor at a temperature higher than that of the seawater. The spray thus evaporates on contact with the exterior of the tube and provides the cooling needed for the internal condensation. Considering

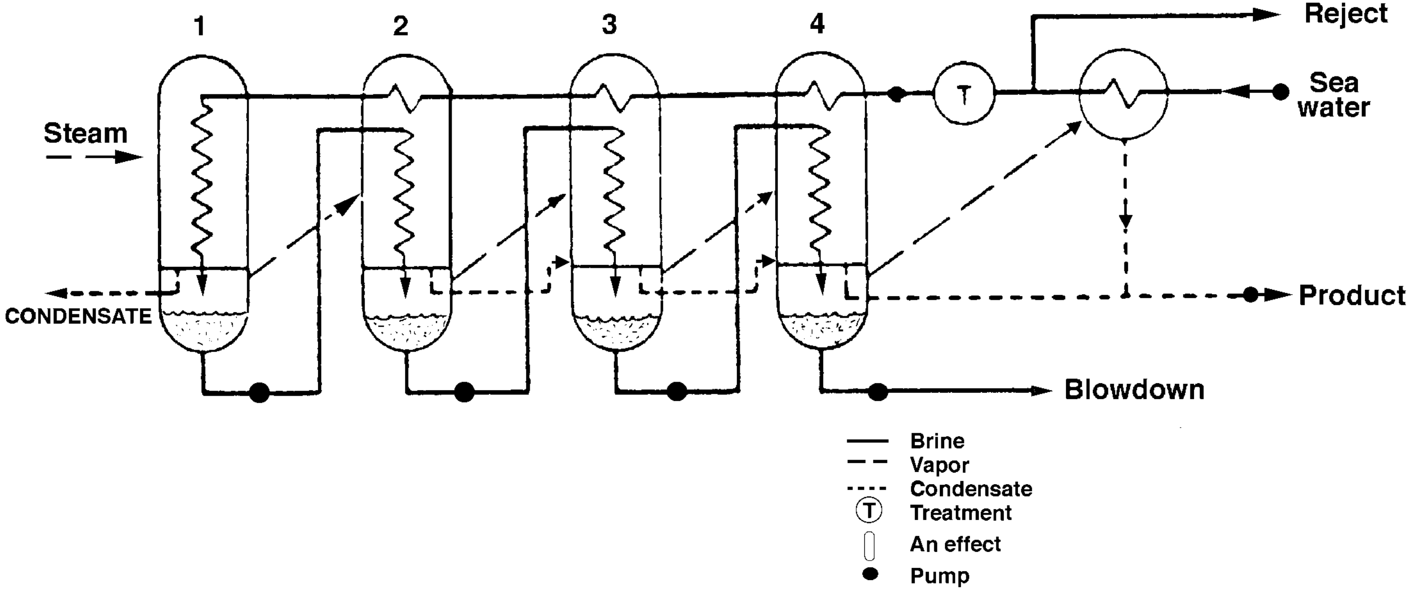

FIGURE 20.6.4 Simplified schematic flow diagram of a typical four-effect VTE desalination plant.

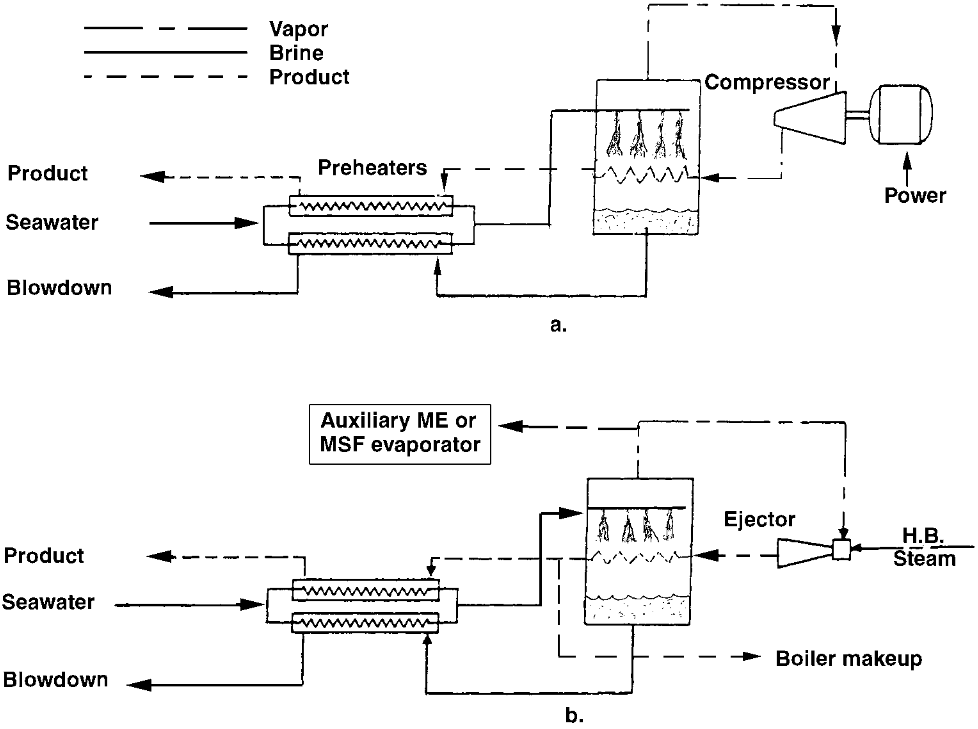

FIGURE 20.6.5 Schematic flow diagram of a basic horizontal-tube VC desalination plant (a) with mechanical, motor-driven compressor; (b) with a thermo-compressor, using an ejector.

the fact that the energy required for vapor compression over a typical overall temperature difference of 4°C and a vapor compressor efficiency of 0.8 is 34 kJ/kg (easily calculated from an enthalpy balance), and that the latent heat of condensation is about 2400 kJ/kg, one can see that a small amount of compression energy enables a large amount of heat to be used internally for desalination. One can thus envisage the VC plant as a large flywheel, wheeling a large amount of energy around at the expense of a small amount needed for sustaining its motion.

The compressor can be driven by electric motors, gas or steam turbines, or internal combustion (usually diesel) engines. The compressor can also be a steam-driven ejector (Figure 20.6.5b), which improves plant reliability because of its simplicity and absence of moving parts, but also reduces its efficiency because an ejector is less efficient than a mechanical compressor. In all of the mentioned thermally driven devices, turbines, engines, and the ejector, the exhaust heat can be used for process efficiency improvement, or for desalination by an additional distillation plant.

Figure 20.6.6 shows a multi-effect VC plant. Using more than a single effect reduces the vapor volume that needs to be compressed. Furthermore, the overall required heat transfer area is also decreased because much of the single-phase heat transfer process in the preheater of the single-effect plant is replaced by the high-heat-transfer condensation–evaporation processes in the effects. Although the ME feature also increases the required compression ratio, the cost of produced water is reduced overall.

Further detail about VC desalination can be found in Steinbruchel and Rhinesmith (1980), Khan (1986), and Standiford, (1986b).

Solar Distillation

The benefits of using the nonpolluting and practically inexhaustible energy of the sun for water desalination are obvious. Furthermore, many water-poor regions also have a relatively high solar flux over a

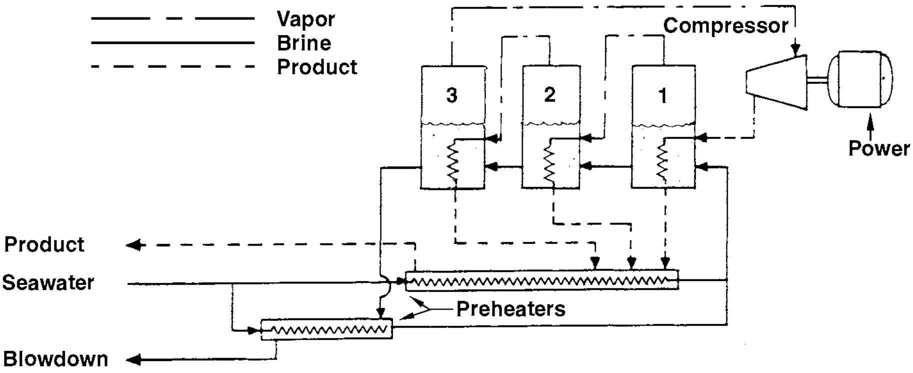

FIGURE 20.6.6 Schematic flow diagram of a ME vapor compression submerged-tube desalinaton plant with three effects.

large fraction of the time. The major impediment in the use of solar energy is economical: the diffuse nature of solar energy dictates the need for constructing a large solar energy collection area. For example, assuming a single-effect solar still efficiency of 50% (which is the upper practical limit for conventional designs), the still would produce at most about 3.5 to 4.8 kg fresh water per m^2 per day, or a 208 to 286 m^2 solar still would be required to produce 1 m^3 of fresh water per day. More realistic still efficiencies increase the area requirement about twofold.

Shown in Figure 20.6.7, a typical solar still consists of a saline water container in which the water is exposed to the sun and heated by it. The temperature rise to above ambient causes net evaporation of the saline water, thus separating pure water vapor from the solution. The vapor condenses on the colder cover, and this destilled water flows to collection troughs.

Solar stills of the type depicted in Figure 20.6.7, in many sizes and constructional variants, have been built and used successfully in many countries in the world. They are simple, easy to construct, reliable, and require very little maintenance although in some regions the covers must be cleaned frequently from accumulated dust or sand.

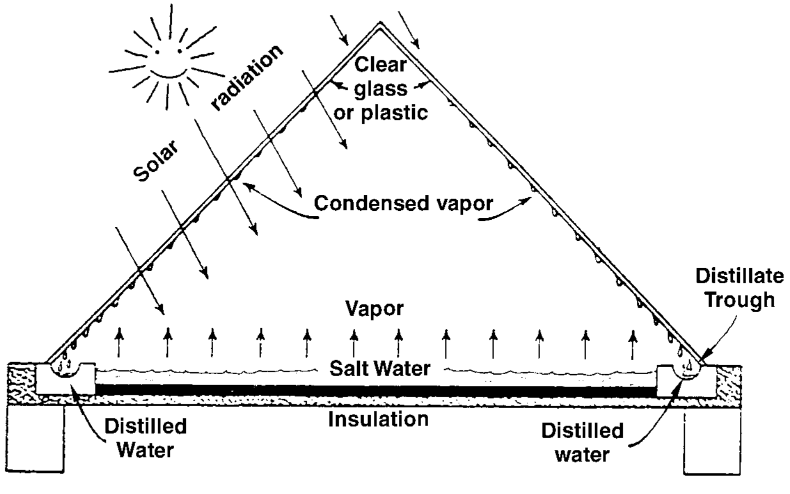

FIGURE 20.6.7 A typical basin-type solar still.

Since the heat of condensation in single-effect stills of the type shown in Figure 20.6.7 is lost to the ambient, more-energy-efficient operation can obviously be achieved in a multi-effect design, where the heat of condensation is used to evaporate additional saline water. A number of such stills were built and tested successfully, but are not commercially competitive yet.

Solar stills integrate the desalination and solar energy collection processes. Another approach to solar desalination is to use separately a conventional desalination process and a suitable solar energy supply system for it. Any compatible desalination and solar energy collection processes could be used. Distillation, such as MSF or ME, can be used with heat input from solar collectors, concentrators, or solar ponds (Hoffman, 1992; Glueckstern, 1995). Net average solar energy conversion efficiencies of solar collectors (Rabl, 1985; Lior, 1991) are about 25% and of solar ponds (Lior, 1993) about 18%, similar to the efficiencies of solar stills, but the MSF or ME plants can operate at preformance ratios of 10 or more, thus basically increasing the freshwater production rate by at least tenfold, or reducing the required solar collection area by at least tenfold for the same production rate.

Solar or wind energy can also be used for desalination processes that are driven by mechanical or electrical power, such as VC, RO, and ED. The solar energy can be used to generate the required power by a variety of means, or photovoltaic cells can be used to convert solar energy to electricity directly.

Freeze Desalination

It is rather well known that freezing of saline water solutions is an effetive separation process in that it generates ice crystals that are essentially salt-free water, surrounded by saline water of higher concentration. This process requires much less energy than distillation, and the problems of corrosion and scaling are markedly reduced due to the much lower operating temperatures. Several pilot plants were constructed and have proven concept viability. Nevertheless, the process has not yet reached commercial introduction for several reasons, such as the difficulty in developing efficient and economical compressors for vapor with the extremely high specific volume at the low process pressure, and difficulties in maintaining the vacuum system leak free and in effecting reliable washing of the ice crystals. A review of freeze desalination processes is given by Tleimat (1980).

Membrane Separation Processes

Reverse Osmosis (RO)

Separation of particulate matter from a liquid by applying pressure to the liquid and passing it through a porous membrane, whereby particles larger than the pore size remain on the upstream side of the membrane and the liquid flows to its downstream side, is well known as *filtration*. Semipermeable very dense membranes that actually separate salt molecules (ions) from the water, by similarly keeping the salt on the upstream side and allowing the pressurized pure water to flow through the membrane, were developed in the 1950s. The reverse of this process, **osmosis**, is well known: for example, if a membrane is placed to separate water from an aqueous salt solution, and the membrane is semipermeable (here meaning that it permits transfer of water only, not the salt components in the aqueous solution), the water will tend naturally to migrate through this membrane into the salt solution. Osmosis is, for example, the major mass transport phenomenon across living cells. The driving force for this water flux is proportional to the concentration difference between the two sides of the membrane, and is exhibited as the so-called **osmotic pressure**, which is higher by 2.51 MPa on the water side of the membrane for typical seawater at 25°C. If a pressure higher than the osmotic pressure is applied on the saline solution side of the membrane, the water flux can be reversed to move pure water across the membrane from the saline solution side to the pure water one. This process is called *reverse osmosis* (and sometimes *hyperfiltration*), and is the basic principle of RO desalination

Unlike filtration of particulates, the selective "filtration" of the water in RO is not due to the relationship of the membrane pore size to the relative sizes of the salt and water molecules. Rather, one way to explain

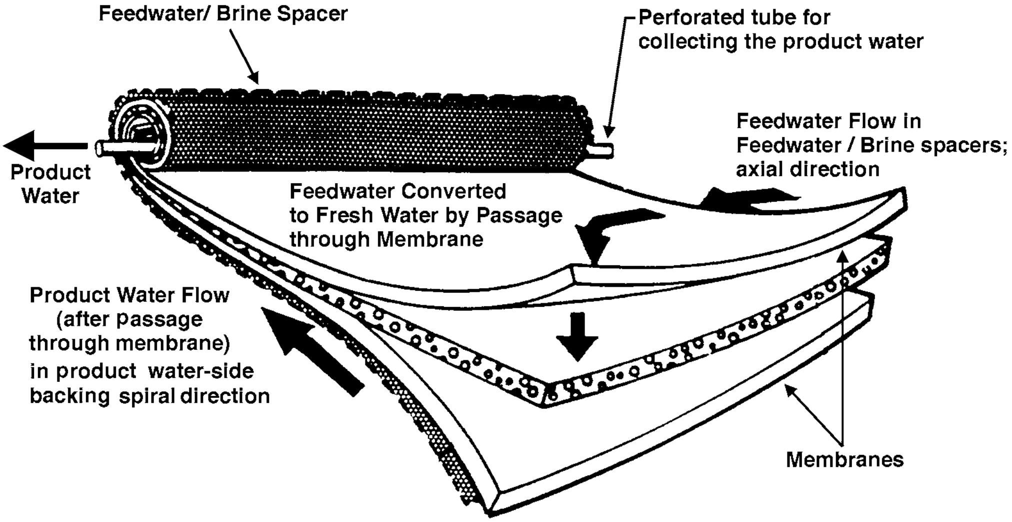

FIGURE 20.6.8 A spiral-wound RO membrane element.

the process is that the very thin active surface layer of the membrane forms hydrogen bonds with water molecules and thus makes them unavailable for dissolving salt. Salt thus cannnot penetrate through that layer. Water molecules approaching that layer are, however, transported through it by forming such hydrogen bonds with it and in that process displacing water molecules that were previously hydrogen bonded at these sites. The displaced water molecules then move by capillary action through the pores of the remainder of the membrane, emerging at its other side.

The most prevalent membrane configurations used in RO plants are of the spiral-wound or hollow-fiber types. The basic spiral-wound-type module (Figure 20.6.8) is made of two sheets placed upon each other and rolled together in an increasing diameter spiral around a cylindrical perforated tube. One of the sheets is in the form of a sandwich typically composed of five layers bonded together along three edges. The two outer layers are the semipermeable membranes. Each of them is backed by a porous material layer for mechanical strength, and the very central layer is a thicker porous material layer that takes up the produced fresh water. The second sheet is a porous mesh through which the high-pressure saline water feed is passed in an axial direction. Product water separates from the saline solution and permeates through the two adjacent semipermeable membranes into the central product water–carrying layer, which conducts it spirally to the unbonded edge of the "sandwich" and to the inner perforated tube. The semipermeable membranes are typically made from cellulose acetate, and more recently from composites of several polymers.

Hollow fiber modules have a configuration similar to a shell-and-tube heat exchanger, with the fibers taking the place of the tubes. A very large number of typicallly 25 to 250 μm outside-diameter semipermeable hollow fibers (wall thickness typically 5 to 50 μm) are bundled together and placed in a saline water pressure vessel. The hollow core of each fiber is sealed on one end. The pressurized saline water is brought into the module (through a central porous feed tube, Figure 20.6.9) to circulate on the exterior surface of the fibers, and water permeates through the fiber wall into its hollow core, through which it flows to a permeate collection manifold at the open end of the fiber bundle. The increasingly concentrated saline water flows radially and is discharged at the exterior shell of the bundle. The hollow fibers are typically made of polyamide or cellulose triacetate, and offer about 20 fold more surface (separation) area per unit volume than the spiral-wound configuration.

The basic approximate equation for the separation process gives the water flux $\dot{m}''_w$ (kg/m^{2}sec) across an RO membrane, in the absence of fouling, as

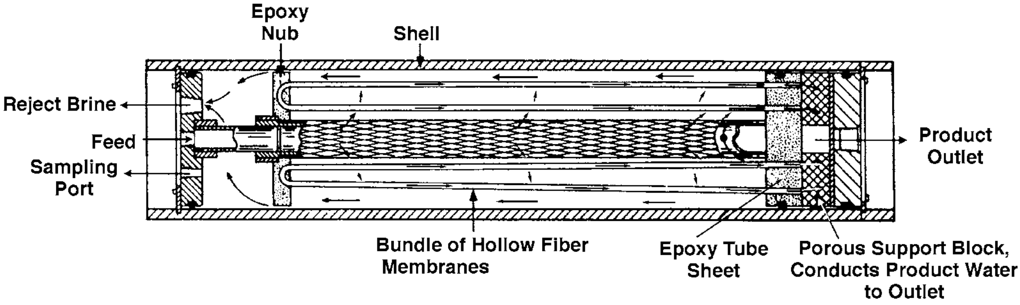

FIGURE 20.6.9 A hollow-fiber RO membrane module. (Du Pont Permasep™.)

$$\dot{m}_w'' = K_{pe} K_{cf}\left[\left(P_f - P_p\right) - \left(\pi_f - \pi_p\right)\right] \tag{20.6.10}$$

where

K_{pe} *water permeability constant* of the membrane (in kg/m²sec Pa), typically increasing strongly as the temperature rises: a plant designed to operate at 20°C may produce up to 24% more water if the water temperature is 28°C,

K_{cf} *compaction correction factor* (dimensionless) which corrects for the fact that the flux is reduced due to densification of the barrier layer (a phenomenon similar to creep) of the membrane, and which increases with the operating pressure and temperature. It is often calculated by the relationship

$$K_{cf} = BC(T)C(P)C(t) \tag{20.6.11}$$

where B is a constant,

$C(T)$ represents the temperature dependence of the Compaction Correction Factor for the particular membrane of interest,

$C(P)$ represents its pressure dependence: while a higher pressure difference across the membrane is shown in Equation (20.6.10) to increase the water flux, higher feed pressure (P_f) also tends to compact the membrane and thus reduce its water flux, typically according to

$$C(P) = P_f^n \tag{20.6.12}$$

where n is a negative number,

and where the time dependence $C(t)$ is represented by

$$C(t) = t^m \tag{20.6.13}$$

where t is the operating time (say, in days) and m is a negative number depending on the membrane.

P water or saline solution pressure (Pa),

π osmotic pressure (Pa),

and the subscripts f and p pertain to the saline feed water and to the desalted product water, respectively.

The required membrane area A can be estimated by

$$A = \frac{\dot{m}_p}{\dot{m}_p'' f} \tag{20.6.14}$$

where $\dot{m}_p$ is the freshwater mass production rate of the plant (kg/sec), and f ($0 < f \leq 1.0$) is the *area utilization factor* that corrects for the fact that the membrane surface is incompletely in contact with the saline water feed stream due to the porous mesh and other devices, such as turbulence promoters, placed in the feed stream path; in a good design $f > 0.9$.

Examination of Equation (20.6.10) shows that water separation rate increases with the water permeability constant K_{pe}. Unfortunately, so does the salt flux across the membrane, resulting in a saltier product. An approximation for this salt flow is

$$\dot{m}_s = KK_s\left(C_{fm} - C_p\right) \tag{20.6.15}$$

where

$\dot{m}_s$ = salt mass transfer rate across the membrane, kg/sec,
K = a proportionality constant, dimensionless,
K_s = *salt permeation constant,* kg/sec, which increases with pressure and temperature.

The salinity of the product water (C_p) can be estimated by the formula

$$C_p = K_{cp}(1 - \eta)\overline{C} \tag{20.6.16}$$

where

K_{cp} = *concentration polarization coefficient,* $\equiv C_{fm} / \overline{C}$ is a measure of the increase of the feedwater salinity at the membrane wall beyond that of the bulk solution,
C_{fm} = salt concentration at the membrane wall,
$\overline{C}$ = bulk salinity of the saline water feed, $\approx (C_f + C_r)/2$,
C_r = salt concentration of the reject brine,
η = *salt rejection factor,* $\equiv$(amount of salts rejected by the membrane)/(amount of salts in the brine feed).

The pressure to be used for RO depends on the salinity of the feed water, the type of membrane, and the desired product purity. It ranges form about 1.5 MPa for low feed concentrations or high-flux membranes, through 2.5 to 4 MPa for brackish waters, and to 6 to 8.4 MPa for seawater desalination. In desalination of brackish water, typical product water fluxes through spiral-wound membranes are about 600 to 800 kg/(m^2day) at a recovery ratio (RR) of 15% and an average salt rejection of 99.5%, where

$$\mathrm{RR} = \frac{\dot{m}_p}{\dot{m}_f} \cong 1 - \frac{C_f}{C_r} \tag{20.6.17}$$

The fluxes in hollow-fiber membranes used in seawater desalination are 20- to 30-fold smaller, but the overall RO system size does not increase, because the hollow-fiber membranes have a much larger surface area per unit volume. The RR and salt rejection ratio are similar to those of spiral-wound membranes.

Since the concentrated reject brine is still at high pressure, it is possible to recover energy by passing this brine through hydraulic turbines, and thus reduce the overall energy consumption by up to 20%. The energy requirements of seawater RO desalination plants with energy recovery are about 5 to 9 kWh, or 18 to 33 MJ, of mechanical or electric power per m^3 fresh water produced. In comparison, the MSF desalination process requires about 120 to 280 MJ of heat and about 15 MJ of mechanical/electric power (for pumping and auxiliaries) per m^3. The energy requirement of the RO process is thus smaller than that of the MSF process even if the RO energy requirement is multiplied by the thermal-to-mechanical (or electrical) power conversion factor of 3 to 4. The specific *exergy* consumption of the MSF process using 120°C steam is about 2- to 3-fold higher than that of the RO process, but becomes comparable in magnitude if the steam temperature is lowered to 80°C.

The life of membranes is affected by gradual chemical decomposition or change. For example, cellulose acetate membranes **hydrolyze** with time. The rate of hydrolysis has a steep minimum at a solution pH of 4.5 to 5.0, and increases drastically with temperature.

Membranes are susceptible to plugging by dirt and to deterioration in their selectivity caused by various species present in the saline water. Careful pretreatment of the feed water is therefore necessary. It typically consists of clarification, filtration, chlorination for destroying organic matter and microorganisms, removal of excess chlorine to prevent membrane oxidation, and dosing with additives to prevent calcium sulfate scaling and foam formation. Periodical chemical or mechanical cleaning is also necessary. Pretreatment and cleaning are significant and increasing fractions of the RO plant capital and operating costs.

Further detail about RO desalination can be found in Sourirajan and Matsuura (1985) and Amjad (1993).

Electrodialysis (ED)

In ED, the saline solution is placed between two membranes, one permeable to cations only and the other to anions only. A direct electrical current is passed across this system by means of two electrodes, cathode and anode, exposed to the solution (Figure 20.6.10). It causes the cations in the saline solution to move toward the cathode, and the anions to the anode. As shown in Figure 20.6.10, the anions can leave the compartment in their travel to the anode because the membrane separating them from the anode is permeable to them. Cations would similarly leave the compartment toward the cathode. The exit of these ions from the compartment reduces the salt concentration in it, and increases the salt concentration in the adjacent compartments. Tens to hundreds of such compartments are stacked together in practical ED

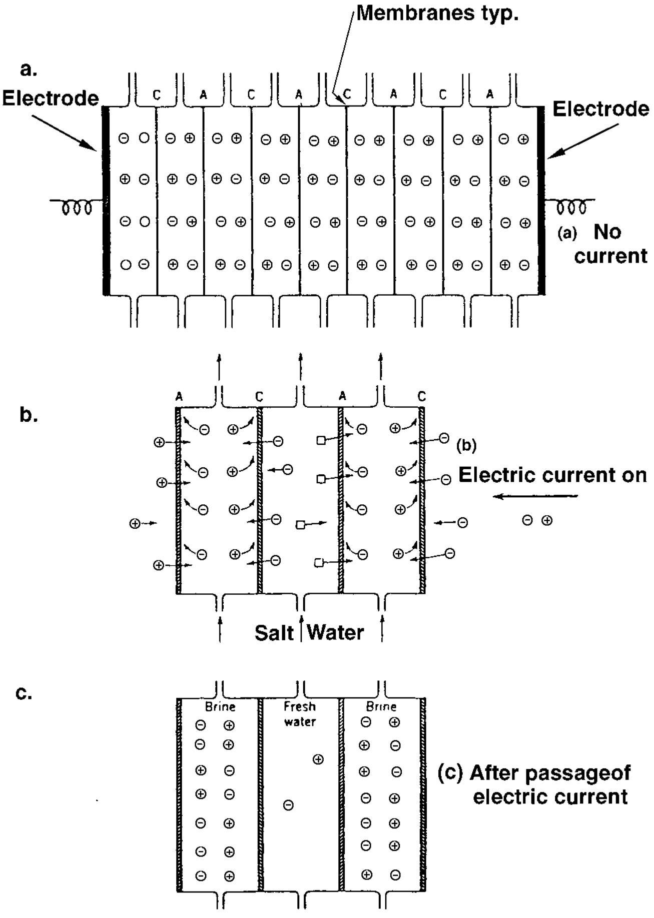

FIGURE 20.6.10 The ED process. *C* and *A* are cation- and anion-permeable membranes, respectively. Application of electric current causes ion transport in a way that salt is depleted in alternate compartments, and enriched in the remaining ones.

plants, leading to the creation of alternating compartments of fresh and salt-concentrated water. ED is a continuous-flow process, where saline feed is continuously fed into all compartments and the product water and concentrated brine flow out of alternate compartments. The flow along the membranes also improves the mass transport there, and the separators between the membranes are constructed to provide good flow distribution and mixing on the membrane surfaces. Membrane sizes are roughly 0.5 × 1 m, spaced about 1 mm apart. Many typed of polymers are used to manufacture these ion-exchange selective membranes, which are often reinforced by strong fabrics made from other polymers or glass fibers.

Careful and thorough feed water pretreatment similar to that described in the section on RO is required. Pretreatment needs and operational problems of scaling are diminished in the electrodialysis reversal (EDR) process, in which the electric current flow direction is periodically reversed (say, three to four times per hour), with simultaneous switching of the water flow connections. This also reverses the salt concentration buildup at the membrane and electrode surfaces, and prevents concentrations that cause the precipitation of salts and scale deposition.

The voltage used for ED is about 1 V per membrane pair, and the current flux is of the order of 100 A/m^2 of membrane surface. The total power requirement increases with the feed water salt concentration, amounting to about 10 MW/m^3 product water per 1000 ppm reduction in salinity. About half this power is required for separation and half for pumping. Many plant flow arrangements exist, and their description can be found, along with other details about the process, in Shaffer and Mintz (1980) and Heitman (1991).

Defining Terms

Boiling point elevation: The number of degrees by which the boiling point temperature of a solution is higher than that of the pure solute at the same pressure.

Flash evaporation: An evaporation process that occurs when a liquid with a free surface is exposed to its vapor, where the vapor is below the saturation pressure corresponding to the temperature of the liquid. The process is typically vigorous, accompanied by rapid growth of bubbles and associated turbulence in the liquid.

Hydrolysis: Decompostion in which a compound is split into other compounds by taking up the elements of water.

Osmosis: The diffusion process of a component of a solution (or mixture) across a semipermeable membrane, driven by the concentration difference (or gradient) of that component across the membrane.

Osmotic pressure: The minimal pressure that has to be applied to the solution (mixture) on the lower concentration side of a membrane permeable to one solution component, for stopping the osmosis of that component through the membrane.

Further Information

The major texts on water desalination written since the 1980s are Spiegler and Laird (1980), Khan, (1986) (contains many practical design aspects), Lior (1986) (on the measurements and control aspects), Heitman (1990) (on pretreatment and chemistry aspects), and Spiegler and El-Sayed (1994) (an overiew primer). Extensive data sources are provided in George et al. (1975) and M. W. Kellog (1975).

The two major professional journals in this field are *Desalination, The International Journal on the Science and Technology of Desalting and Water Purification* and *Membrane Science*, which often addresses membrane-based desalination processes, both published by Elsevier, Amsterdam.

The major professional society in the field is the International Desalination Association (IDA) headquartered at P.O. Box 387, Topsfield, MA 01983. IDA regularly organizes international conferences, promotes water desalinaton and reuse technology, and is now publishing a trade magazine T*he International Desalination & Water Reuse Quarterly.*

The *Desalination Directory* by M. Balaban Desalination Publications, Mario Negri Sud Research Institute, 66030 Santa Maria Imbaro (Ch), Italy, lists more than 5000 individuals and 2000 companies and institutions in the world of desalinaiton and water reuse.

Two useful (though by now somewhat dated) books on desalination are by Howe, E. D. 1974. *Fundamentals of Water Desalination*, Marcel Dekker, New York, and by Porteous, A. 1975. *Saline Water Distillation Processes*, Longman, London.

Much information on oceans and seawater properties is avaiable in the book by Riley, J. P. and Skinner, Eds. 1975. *Chemical Oceanography*, Academic Press, New York.

20.7 Noise Control

Malcolm J. Crocker

Introduction

Noise is usually defined as unwanted sound. Noise in industry experienced over an extended period can cause hearing loss. Noise in other environments — in buildings, vehicles, and communities from a variety of sources causes speech interference, sleep disturbance, annoyance, and other effects (Crocker, 1997b,d). Noise propagates as sound waves in the atmosphere and as vibration in buildings, machinery, vehicles, and other structures. Noise can be controlled at the *source*, in the *path*, or at the *receiver*. The ear is more sensitive to noise in the mid- to high-frequency range, but fortunately high-frequency is easier to control than low-frequency noise. Several passive methods of noise and vibration control are described. An example of successful noise control is the considerable reduction in passenger jet aircraft noise in the last several years which has made them considerably quieter.

Sound Propagation

Sound waves propagate rather like ripples on a lake when a stone is thrown in (Crocker, 1997c). The ripples spread out from the source of the disturbance as circular waves until they reach a solid body or boundary (such as the lake edge) where reflections occur. The water does not flow from the source, but the disturbance propagates in the form of momentum and energy which is eventually dissipated. Sound waves in air cannot be seen but behave in a similar manner. Sound waves propagating in three dimensions from a source of sound are spherical rather than circular like the two-dimensional water wave propagation. Sound waves propagate at the wave speed (or *sound speed* c) which is dependent only on the absolute temperature T. It is 343 m/sec (1120 ft/sec) at a normal atmospheric temperature of 20°C. The *wavelength* λ of sound is inversely proportional to the *frequency* f in cycles/sec (known as hertz or Hz) and is given by $\lambda = c/f$ Hz. The sound waves result in fluctuations in the air pressure as they propagate. The air pressure difference from the mean atmospheric pressure is defined as the *sound pressure*. A logarithmic measure, the sound pressure level SPL or L_p, is usually used with sound and noise and the units are *decibels* (dB). The sound pressure level is $L_p = 10 \log_{10} (p^2 / p_{\text{ref}}^2)$, where p is the rms sound pressure and p_{ref} is the reference sound pressure 20 μPa (or 20×10^{-6} N/m^2). See Figure 20.7.1 (Crocker, 1997c).

Human Hearing

The human ear has a wide frequency response from about 15 or 20 Hz to about 16,000 Hz (Crocker, 1975; Greenberg, 1997). The ear also has a large dynamic range; the ratio of the loudest sound pressure we can tolerate to the quietest sound that we can hear is about ten million (10^7). This is equivalent to 140 dB. The ear can be divided into three main parts: the outer, middle, and inner ear. The outer ear, consisting of the fleshy pinna and ear canal, conducts the sound waves onto the ear drum. The middle ear converts the sound pressure at the ear drum into the mechanical motion of three small bones (named auditory ossicles: malleus, incus, and stapes) which in turn convert the mechanical motion into waves in the inner ear. Hair cells in the inner ear respond to the excitation and send neural impulses along the auditory nerves to the brain (Figure 20.7.2).

The higher the sound pressure level of a sound, the louder it normally sounds, although the frequency content of the sound is important too. The ear is most sensitive to sound in the mid-frequency range and

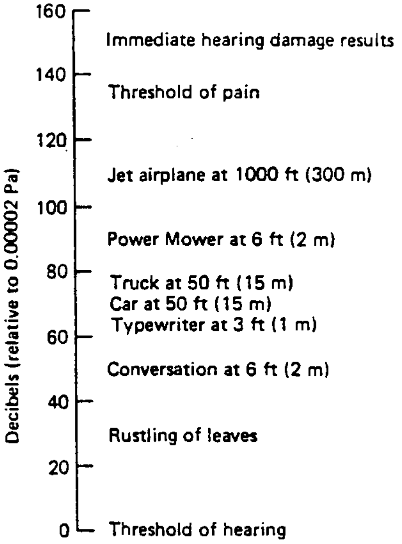

FIGURE 20.7.1 Some typical sound pressure levels.

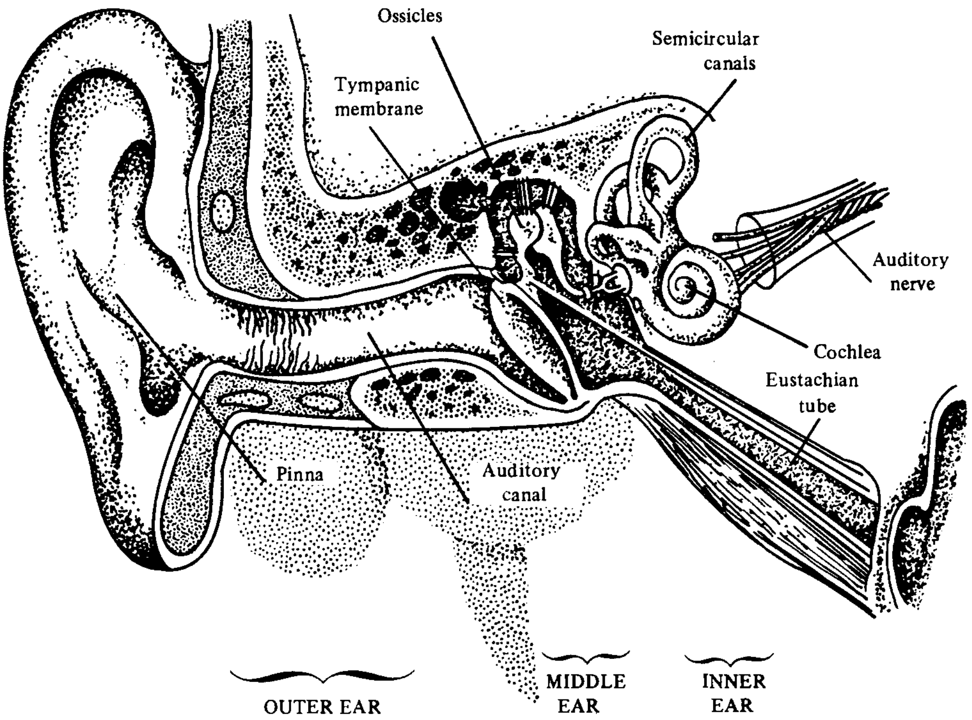

FIGURE 20.7.2 Cross section of the human ear showing the three main parts: outer, middle, and inner ear.

hears sound only poorly at lower frequencies (below 200 or 300 Hz). Most people have a maximum sensitivity to sound at about 4000 Hz (corresponding to a quarter wave resonance in the ear canal, with a pressure maximum at the eardrum). Electrical filters have been produced corresponding approximately to the frequency response of the ear. The A-weighting filter is the one most used and it filters off a considerable amount of the sound energy at low frequencies. The sound pressure level measured with an A-weighting filter is normally known as the A-weighted sound level (or the sound level for short). The anatomy and functioning of the ear are described more completely in several books (Crocker, 1997; Greenberg, 1997).

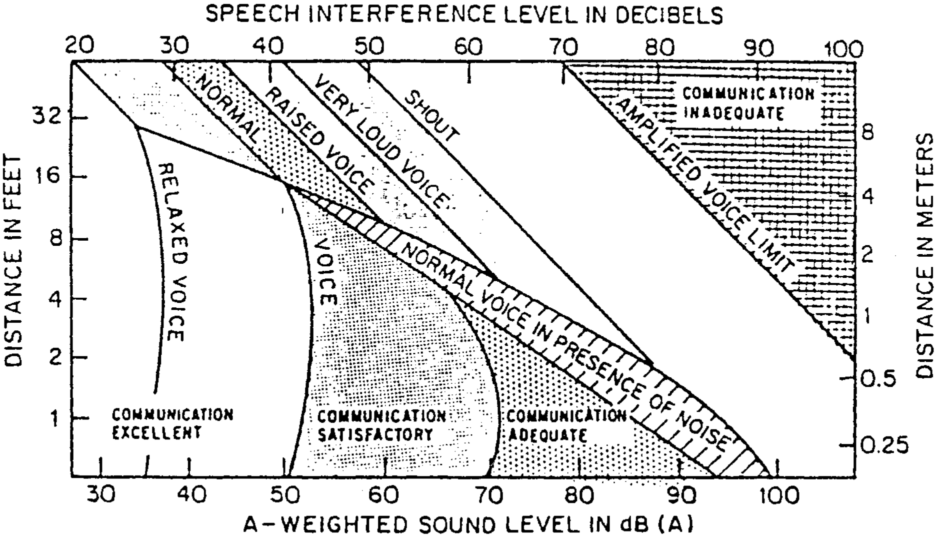

FIGURE 20.7.3 Recommended distances between speaker and listener for various voice levels for just reliable speech communication. (From C.M. Harris *Handbook of Noise Control,* McGraw-Hill, New York, 1979. With permission.)

Noise Measures

There are several rating measures and descriptors used to determine human response to noise. Only a few of the most important can be discussed here. The reader will find more such measures discussed in the literature. [1] Criteria derived from such measures can be used to produce regulations or legislation.

The speech interference level (SIL) is a measure used to evaluate the effect of background noise on speech communication. The SIL is the arithmetic average of the sound pressure levels of the interfering background noise in the four octave bands with center frequencies of 500, 1000, 2000 and 4000 Hz.[1,6]

The speech interference level of the background noise is calculated; then this may be used in conjunction with Figure 20.7.3 to determine if communication is possible at various distances for different voice levels. This figure is for male voices. Since the average female voice is normally quieter, for female voices the horizontal scale should be moved to the right by 5 dB. Use of the results obtained with Figure 20.7.3 and criteria for various spaces in buildings enable decisions to be made whether they are suitable for their desired uses.

The equivalent sound level L_{eq} is the A-weighted sound pressure level averaged over a suitable time period T. The averaging time T can be chosen to be a number of minutes, hours or days, as desired.

$$L_{\mathrm{eq}} = 10\log_{10}\left[(1/T)\int p_A^2\, dt/p_{\mathrm{ref}}^2\right] dB$$

where p_{A} is the instantaneous sound pressure measured using an A-weighting frequency filter. The L_{eq} is also sometimes known as the *average sound level* L_{AT}.

The *day-night equivalent sound level* (DNL) or L_{dn} is a measure that accounts for the different human response to sound at night. It is defined (Crocker, 1997d) as:

$$L_{\mathrm{dn}} = 10\log_{10}\left\{(1/24)\left[15\left(10^{L_d/10}\right) + 9\left(10^{(L_n+10)/10}\right)\right]\right\} dB$$

where L_d is the 15-hr daytime A-weighted equivalent sound level (from 0700 to 2200 hr) and L_n is the 9-hr nighttime equivalent sound level (from 2200 to 0700 hr). The nighttime level is subjected to a 10-dB penalty because noise at night is known to be more disturbing than noise during the day.

There is some evidence that noise that fluctuates markedly in level is more annoying than noise which is steady in level. Several noise measures have been proposed to try to account for the annoying effect of these fluctuations. The percentile levels are used in some measures. The *percentile level* L_n is defined to be the level exceeded n% of the time (Crocker, 1997d). The A-weighted sound level is normally used in Ln.

Response of People to Noise and Noise Criteria and Regulations

In industry, noise is often intense enough to interfere with speech and to create noise conditions that are hazardous to hearing. By using Figure 20.7.3 it is seen that if the SIL is above 50 dB, then the noise will interfere with normal speech communication between male voices at 4 m. If it is above 60 dB, then speech communication even when shouting is barely possible at the same distance. For women the comparable values of SIL are 45 and 55 dB at the same distance. If the SIL is 90 dB, then communication between male voices is only possible at distances less than 0.25 m, even when shouting. A-weighted sound levels are sometimes used instead of SIL values but with somewhat less confidence. It is seen that if one has difficulty in communicating in an industrial situation, then the A-weighted sound level is likely to be above 90 dB. In the United States, OSHA regulations start at this level for an 8-hr period. There is a halving in the allowable exposure time for every 5-dB increase in sound level. See Table 20.7.1. In almost all other countries the allowable exposure time is halved for every 3-dB increase in sound level (Ward, 1997).

Noise in communities is caused by many different sources. In most countries, the maximum equivalent A-weighted sound level L_{eq} is recommended for evaluating different types of noise source (Gottlob, 1995). In some countries there are regulations which use L_{eq} for road traffic noise and railroad noise, although some countries use L_{10} (e.g., the U.K.) or L_{50} (e.g., Japan) for planning permission in which road traffic noise is of concern (Crocker, 1997d; Gottlob, 1995). In the United States the L_{dn} has been used for community noise situations involving aircraft noise at airports and road traffic noise. Table 20.7.2 presents levels of noise given by the U.S. EPA and several other bodies to protect public health. Social surveys in several countries have been used to relate the percentage of respondents highly annoyed by noise to the day-night equivalent sound level, L_{dn} (Crocker, 1997d; Gottlob, 1995). See Figure 20.7.4. (Finegold et al., 1994). It is seen that many studies have shown that aircraft noise appears to be more annoying than other sources, perhaps because of the larger fluctuation in levels with time compared with the other sources. However, some other studies suggest that railroad noise is less annoying than traffic noise and this is borne out by the lower levels used for railroad noise than traffic noise regulations in several European countries (Gottlob, 1995).

Various investigations have shown that noise disturbs sleep (Crocker, 1997d). It is well known that there are several stages of sleep and that people progress through these stages as they sleep. Noise can change the progress through these stages and if sufficiently intense can awaken the sleeper. Recently, sleep disturbance data from several analyses have been reanalyzed and the preliminary sleep disturbance curve

TABLE 20.7.1 Maximum A-Weighted Sound Levels Allowed by the U.S. Occupational Safety and Health Administration (OSHA) for Work Periods Shown during a Workday

Duration per Day (hr)	Sound Level in dB(A)
8	90
6	92
4	95
3	97
2	100
1.5	102
1	105
0.5	110

TABLE 20.7.2 Guidelines from the U.S. Environmental Protection Agency (EPA), World Health Organization (WHO), Federal Interagency on Community Noise (FICON), and Various European Agencies for Acceptable Noise Levels

Authority	Specified Sound Levels	Criterion
EPA Levels Document	$L_{dn} \leq 55$ dB (outdoors) $L_{dn} \leq 45$ dB (indoors)	Protection of public health and welfare with adequate margin of safety
WHO Document (1995)	$L_{eq} \leq 50/55$ dB (outdoors: day) $L_{eq} \leq 45$ dB (outdoors: night) $L_{eq} \leq 30$ dB (bedroom) $L_{max} \leq 45$ dB (bedroom)	Recommended guideline values (Task Force consensus)
U.S. Interagency Committee (FICON)	$L_{dn} \leq 65$ dB	Considered generally compatible with residential development
	$65 \leq L_{dn} \leq 70$ dB	Residential use discouraged
Various European road traffic regulations	$L_{eq} \geq 65$ or 70 dB (day)	Remedial measures required

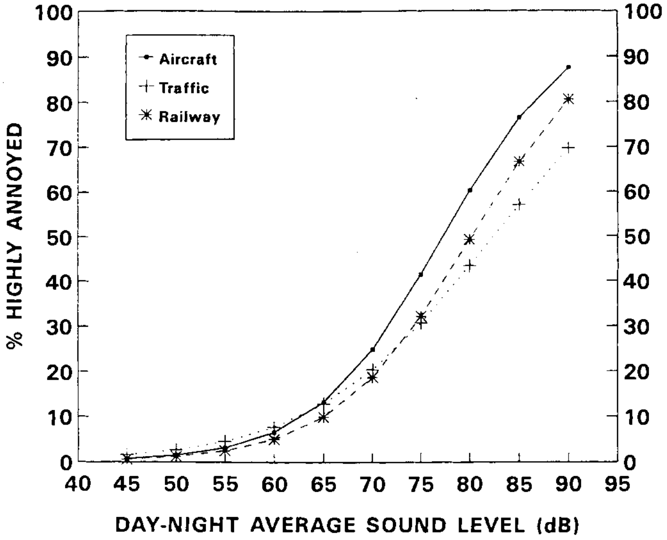

FIGURE 20.7.4 Percentage of survey respondents highly annoyed vs. day-night equivalent sound level for aircraft, road traffic, and railway noise.

given in Figure 20.7.5 has been proposed. A regression fit to these sleep disturbance data (Finegold et al., 1994) gave the following expression (which is also shown graphically in Figure 20.7.5) (Crocker, 1997d; Finegold et al., 1994):

$$\% \text{ Awakenings} = 7.1 \times 10^{-6} L_{AE}^{3.5}$$

where L_{AE} is the indoor A-weighted sound exposure level ASEL.

Noise Control Approaches

The main noise control approaches include use of sound absorption, enclosures, barriers, and vibration isolation and damping (Crocker, 1997c). Most porous materials absorb sound and those materials

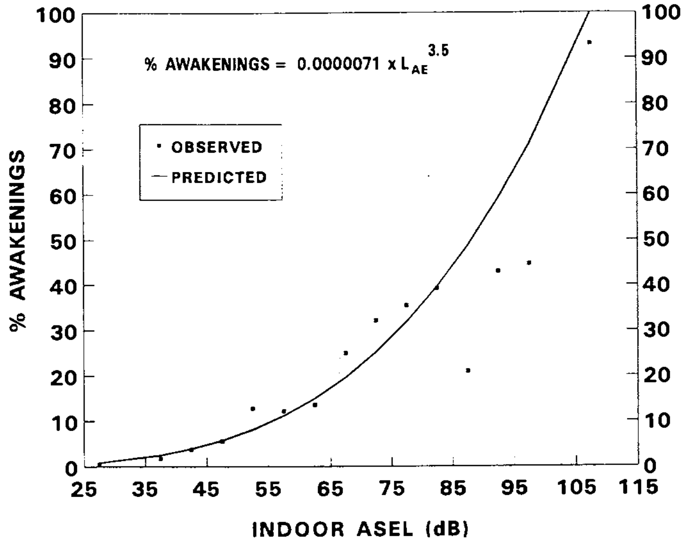

FIGURE 20.7.5 Proposed sleep disturbance curve: percentage of subjects awakened as a function of indoor sound exposure level.

specially made for this purpose include materials such as porous foams and fiberglass. However, ordinary materials such as carpets and drapes are also effective and can be used in building spaces to reduce reverberant sound buildup and noise. Although all these materials are rather ineffective at low frequency, at frequencies above 500 to 1000 Hz they can absorb almost all of the sound energy incident on them and in this case are said to have an absorption coefficient α of one. In industry they are used inside machine enclosures or placed on the walls and inside ceilings of manufacturing buildings to reduce the reverberant noise buildup (Crocker, 1997c).

Enclosures can be used to partially or completely enclose machines (machine enclosures) or to enclose operators of machines (personnel enclosures). The first approach may be regarded as *path* control and the second as *receiver* control. The improvement in noise reduction that these enclosures can achieve is related not only to the so-called transmission loss TL of the enclosure material used, $TL = 10 \log mf - 34$ dB, where m is the mass/unit area of the enclosure walls in kg/m^2 and f is the frequency in Hz, but also to the absorption coefficient α by $10 \log(1/\alpha)$. Thus, enclosures that have massive walls and absorbing material inside are the most effective at reducing noise both as machine enclosures or personnel enclosures. The enclosures should be well sealed to prevent sound being transmitted through leaks. If it is necessary to have a vent or hole in the enclosure for ventilation or for access, then the vent should be lined with sound-absorbing material and be bent or constructed like a labyrinth to try to reduce the direct transmission of noise through the vent or hole. As the relationship for TL indicates, enclosures are generally more effective at high frequency (Crocker, 1997c).

Barriers are used to shield personnel from sound sources. The effectiveness of a barrier depends not only on the effective height of the barrier in wavelengths, but also how far the receiver point is into the sound shadow. Barriers are thus most effective when they are taller (in wavelengths) and thus best for high-frequency noise and also best when placed close to the source or close to the receiver, since such placement increases the shadowing effect. Barriers are used in industry where it is desired to shield personnel from machinery noise sources. It is important in such cases to put sound-absorbing material on the ceiling of the building just above the barrier or on walls just behind a barrier where these surfaces could allow the reflection of sound to bypass the barrier and thus severely reduce its effectiveness (Crocker, 1997c).

The vibration isolation of machine sources from their supports can be particularly useful in reducing the noise produced especially if the machine is small compared with a large flexible support or enclosure that can act as a sounding board and radiate the sound. Soft metal springs or elastomeric isolators are often used as isolators. They should be designed so that the natural frequency of the machine mass on its isolators is much less than the forcing frequency, if possible. Care should be taken that such a design condition does not produce excessive static deflection of the system that could interfere with the proper machine operation. Vibrating pipes and ducts can also be vibration-isolated from walls of buildings using pipe hangers or soft rubber isolators. Vibration breaks made of rubber or similar soft material can be built into elements such as walls in buildings or structural elements in vehicles or machine enclosures to prevent vibration being propagated throughout the building or other structure and being reradiated as noise (Crocker, 1997c).

Damping materials can also be effective at reducing noise when applied properly to structures if their vibration is resonant in nature. Damping materials that are viscous, applied with thicknesses two or three times that of the vibrating metal panel, are particularly effective. Constrained damping layers can be very effective even when the damping layer is relatively thin (Crocker, 1997c).

Figure 20.7.6 shows the reduction in the A-weighted sound level that can be expected using these passive noise control approaches discussed above. Often it is insufficient to use one approach, and greater, more-economic noise reduction can be achieved by using two or more approaches in conjunction.

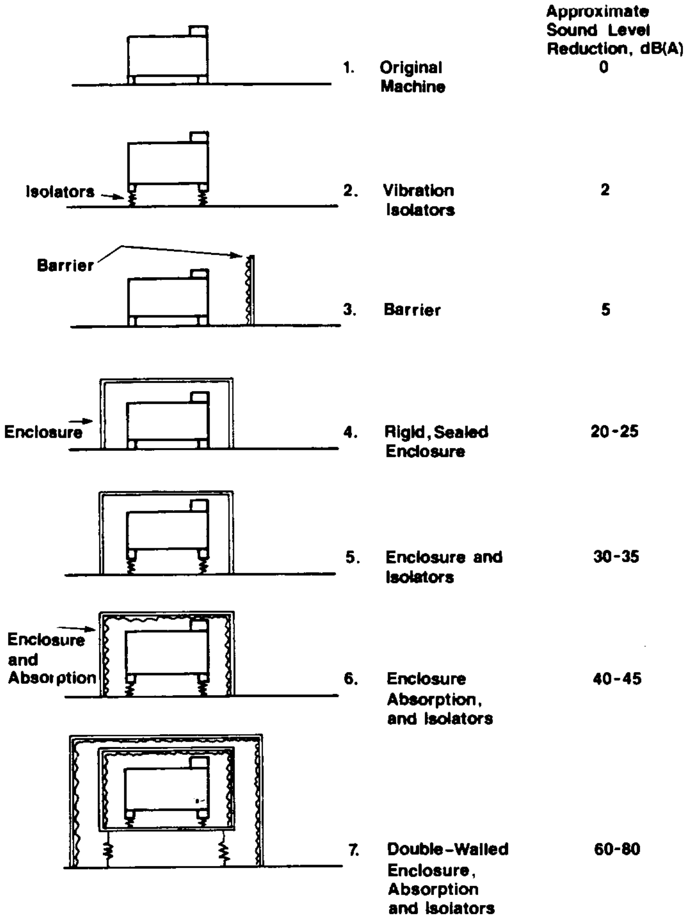

FIGURE 20.7.6 Approximate A-weighted sound level reductions expected from different noise control approaches.

20.8 Lighting Technology

Barbara Atkinson, Andrea Denver, Robert Clear, and James E. McMahon

In this section, we describe the technical and operating characteristics of the general categories of lamps, ballasts, and fixtures in use today.*

Because the purpose of a lamp is to produce light, and not just radiated power, there is no direct measure of lamp efficiency. Instead, a lamp is rated in terms of its **efficacy**,** which is the ratio of the amount of light emitted (lumens) to the power (watts) drawn by the lamp. The metric used to express lamp efficacy is lumens per watt (LPW). The theoretical limit of efficacy is 683 LPW and would be produced by an ideal light source emitting monochromatic radiation with a wavelength of 555 nm. The most efficient white light source in the laboratory provides 275–310 LPW. Of lamps currently on the market, the most efficient white light source, the T5 fluorescent lamp with electronic ballast, produces about 100 LPW. High-pressure sodium (not a white light source) can produce as high as 130 LPW.

The efficacies of various light sources are depicted in Figure 20.8.1. Lamps also differ in terms of their size, color, lifetime, optical controllability, dimmability, **lumen maintenance**,*** reliability, convenience in use, maintenance requirements, disposal, environmental impacts (mercury, lead), and electromagnetic and other emissions (e.g., radio interference, ultraviolet [UV] light, and noise).

---

*Much of the contents of this section have been abstracted and updated from Chapter 12B (Energy Efficient Lighting Technologies and Their Applications in the Commercial and Residential Sectors by Barbara Atkinson, Andrea Denver, James E. McMahon, Leslie Shown, and Robert Clear) published in the CRC *Handbook of Energy Efficiency*, Frank Kreith and Ronald E. West, Eds., 1997.

**The efficacies of fluorescent lamp/ballast combinations reported in this section are based on data from the Advanced Lighting Guidelines 2003, and from the Lawrence Berkeley National Laboratory's Lighting Systems Research Group, 2003.

***Over time, most lamps continue to draw the same amount of power but produce fewer lumens. The lumen depreciation of a lamp refers to the extent to which the lamp sustains its lumen output, and therefore efficacy, over time

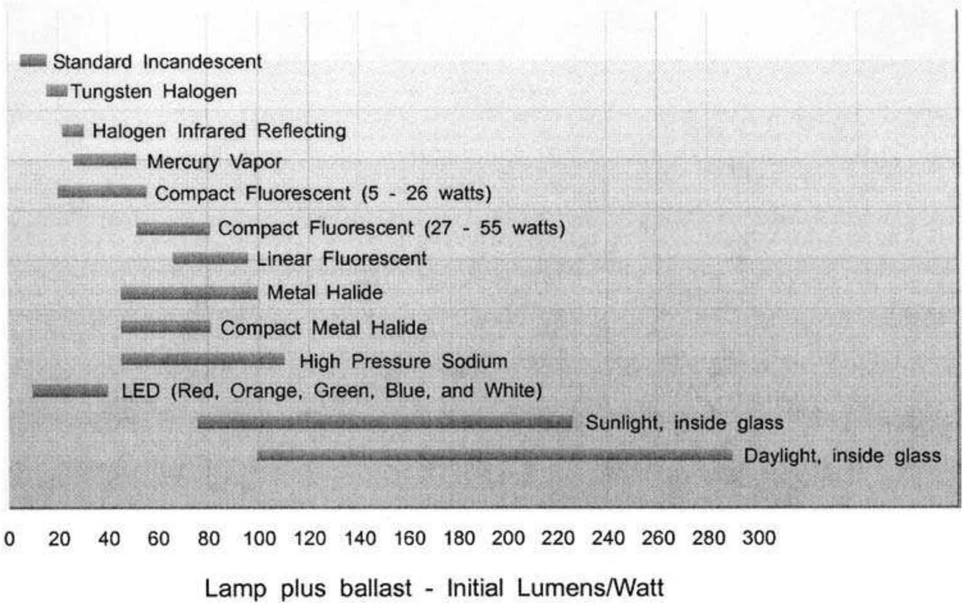

FIGURE 20.8.1 Efficacy comparison of light sources for general lighting. Lamp plus ballast—initial lumens/watts. Ballast watts are included for discharge lamp systems. Sunlight and daylight ranges are calculated inside of single pane clear glass and high performance glass. Source: Advanced Lighting Guidelines, 2003, New Buildings Institute.

The color properties of a lamp are described by its color temperature and its color rendering index. **Color temperature**, expressed in degrees Kelvin (K), is a measure of the color appearance of the light of a lamp. The concept of color temperature is based on the fact that the emitted radiation spectrum of a blackbody radiator depends on temperature alone. The color temperature of a lamp is the temperature at which an ideal blackbody radiator would emit light that is closest in color to the light of the lamp. Lamps with low color temperatures (3000 K and below) emit warm white light that appears yellowish or reddish in color. Incandescent and warm-white fluorescent lamps have a low color temperature. Lamps with high color temperatures (3500 K and above) emit cool white light that appears bluish in color. Cool-white fluorescent lamps have a high color temperature.

The **color rendering index (CRI)** of a lamp is a measure of how surface colors appear when illuminated by the lamp compared to how they appear when illuminated by a reference source of the same color temperature. For color temperatures above 5000 K, the reference source is a standard daylight condition of the same color temperature; below 5000 K, the reference source is a blackbody radiator. The CRI of a lamp indicates the difference in the perceived color of objects viewed under the lamp and under the reference source. There are 14 differently colored test samples, 8 of which are used in the calculation of the general CRI index. The CRI is measured on a scale that has a maximum value of 100 and is an average of the results for the 8 colors observed. A CRI of 100 indicates that there is no difference in perceived color for any of the test objects; a lower value indicates that there are differences. CRIs of 70 and above are generally considered to be good, while CRIs of 20 and below are considered to be poor. Most incandescent lamps have CRIs equal to or approaching 100. Low-pressure sodium lamps have the lowest CRI of any common lighting source; their light is essentially monochromatic.

The **optical controllability** of a lamp describes the extent to which a user can direct the light of the lamp to the area where it is desired. Optical controllability depends on the size of the light-emitting area, which determines the beam spread of the light emitted. Incandescent lamps emit light from a small filament area; they are almost point sources of light and their optical controllability is excellent. In contrast, fluorescent lamps emit light from their entire phosphored area; their light is extremely diffuse and their controllability is poor. In addition, controllability depends on the fixture in which the lamp is used.

Because of their many different characteristics and the variety of applications, no one light source dominates the lighting market. The types of lamps that are commonly available include incandescent, fluorescent, and high-intensity discharge (HID). Induction lighting systems have begun to come into use as well.

Lamps

The *incandescent lamp* was invented independently by Thomas Edison in the U.S. and Joseph Swan in England in the late 1800s. An incandescent lamp produces light when electricity heats the lamp filament to the point of incandescence. In modern lamps the filament is made of tungsten. Because 90% or more of an incandescent lamp's emissions are in the infrared (thermal) rather than the visible range of the electromagnetic spectrum, these lamps are less efficacious than other types of lamps.

The two primary types of standard incandescent lamps are general service and reflector lamps. General service lamps (also known as A-lamps) are the pear-shaped, common household lamps. Reflector lamps, such as flood or spotlights, are generally used to illuminate outdoor areas or highlight indoor retail displays and artwork. They are also commonly used to improve the optical efficiency of downlights (discussed later). Downlights are used where controlling glare or hiding the light source is important. In spite of the fact that they are the least efficacious lamps on the market today, standard incandescent general service lamps are used for almost all residential lighting in the U.S. and are also common in the commercial sector. They have excellent CRIs and a warm color; they are easily dimmed, inexpensive, small, and lightweight, and can be used with inexpensive fixtures. In a properly designed fixture, they permit excellent optical control. In addition, incandescent lamps make no annoying noises, provide no electromagnetic interference, and contain essentially no toxic chemicals. They are simple to install, maintain, and dispose of.

Halogen and *halogen infrared-reflecting (HIR) lamps* are more efficient versions of the incandescent lamp. Halogen lamps produce bright white light and have color temperatures and CRIs that are similar to, or slightly higher than, those of standard incandescent lamps. In addition, they have longer rated lives (2000 or more hours vs. 1000 hours or less), can be much more compact, are slightly more efficacious, and have better lumen maintenance than standard incandescent lamps. Halogen general service lamps are available but are still relatively rare; they offer longer life as well as slightly higher lumen output or lower wattage than standard incandescent lmaps. Halogen technology is also used in small reflector lamps operated on low-voltage transformers. These lamps, also known as dichroics, are used for accent lighting and sparkle in a variety of applications. Reflector lamps using halogen technology have gained market share because they meet the U.S. reflector lamp standards (see below). The HIR technology, which is more efficient than standard halogen, is available in reflector lamps. In general, HIR lamps have a small market share due to their high cost, even though HIR lamps last about 50% longer than regular halogen lamps.

The U.S. Energy Policy Act of 1992 (EPAct) set standards for incandescent reflector lamps that in essence can be met by halogen technology, while standard incandescent reflector lamps do not comply. However, exempted lamps such as bulged reflector (BR) and elliptical reflector (ER) lamps have gained in market share since the standards took effect in 1995. BR and ER lamps employ variations on reflector geometry to more efficiently focus light, but their efficacies are not as high as those of reflector lamps using halogen technology.

Fluorescent lamps came into general use in the 1950s. In a fluorescent lamp, gaseous mercury atoms within a phosphor-coated lamp tube are excited by an electric discharge between two electrodes (cathode and anode). As the mercury atoms return to their ground state, ultraviolet radiation is emitted. This UV radiation excites the phosphor coating on the lamp tube and causes it to flouresce, thus producing visible light (see Figure 20.8.2).

Early fluorescent tubes, and current compact fluorescent lamps as well as some shorter fluorescent tubes, use "preheat start" with an automatic or manual starting switch. "Instant start" lamps use a high voltage to strike the arc of the lamp. Electronic ballasts (discussed later) are available that can instant-start most types of fluorescent lamps. "Rapid start" circuits use low-voltage windings for preheating the

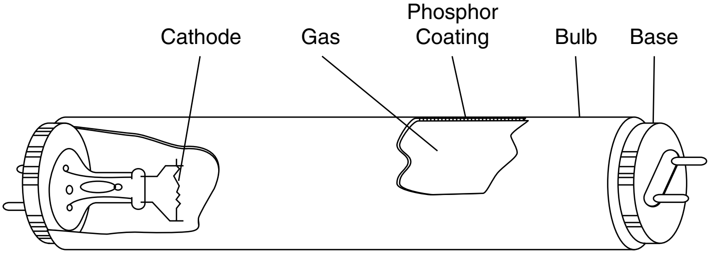

FIGURE 20.8.2 Typical full-size fluorescent lamp. (From Atkinson, B. et al. *Analysis of Federal Policy Options for Improving U.S. Lighting Energy Efficiency: Commercial and Residential Buildings*, Lawrence Berkeley National Laboratory, Berkeley, CA, 1992. With permission.)

electrodes and initiating the arc to start the lamps. "Programmed rapid start" technology further refines the starting circuit.

Fluorescent lamps are far more efficacious than incandescent lamps. The efficacy of a fluorescent lamp system depends on the lamp length and diameter, the type of phosphor used to coat the lamp, the type of ballast used to drive the lamp, the number of lamps per ballast, the temperature of the lamp (which depends on the fixture and its environment), and a number of lesser factors.

The majority of lighting used in the commercial sector is fluorescent. Fluorescent lighting is also common in the industrial sector. The small amount of full-size fluorescent lighting in the residential sector is primarily found in kitchens, bathrooms, garages, and workshops.

EPAct set efficacy standards for 4-ft and 8-ft fluorescent lamps that can be met using reduced wattage, or "energy saver," lamps. These lamps became popular in the 1970s to retrofit full-wattage lamps. The reduced wattage lamp is similar to its full-wattage predecessor, with kypton added to the gas fill and a conductive coating to lower starting voltage. The lumen output is generally reduced proportionate to the wattage reduction.

Fluorescent lamps have long lives and fairly good lumen maintenance. Of the full-size fluorescent lamps available today, *rare-earth phosphor lamps* are the most efficacious. In these lamps, rare-earth phosphor compounds are used to coat the inside of the fluorescent lamp tube. Rare-earth phosphor lamps are also called tri-phosphor lamps because they are made with a mixture of three rare-earth phosphors that produce visible light of the wavelengths to which the red, green, and blue retinal sensors of the human eye are most sensitive. These lamps have improved color rendition as well as efficacy. Fluorescent T8 lamps and those with smaller diameters use rare-earth phosphors almost exclusively. While the reduced wattage halophosphor (cool-white and warm-white) lamps have CRIs of 50 to 60, rare-earth phosphor lamps have CRIs in the 70s and 80s. Standard fluorescent lamps last 12,000 (8-ft) to 20,000 (4-ft) hours.

The most common fluorescent lamps are tubular and 4 feet (1.2 m) in length. Four-foot lamps are also available in U-tube shapes that fit into fixtures with 2-ft dimensions. Lamp tubes with a diameter of 1.5 inches (38 mm) are called T12s, tubes that are 1 inch (26 mm) in diameter are called T8s, and those that are 5/8 inch (16 mm) are called T5s. The 12, 8, and 5 refer to the number of eights of an inch in the diameter of the lamp tube. Lamp tubes are available in other diameters as well. Each type of fluorescent lamp requires a specific ballast, depending on the wattage, length, and current (milliamps) of the lamp.

Four-foot T12 lamps have been available in 34-watt (W) and 40-W versions, with 25-W lamps introduced more recently. The 40-W lamps with halophosphors do not meet EPAct lamp standards, but 40-W lamps are available with rare-earth phosphor technology and higher efficacy that do meet the standards.

T8 lamps, using rare-earth phosphors giving them higher CRIs, were introduced several years ago and have come into wide usage. T5 lamps are an even more recent addition, and have become popular for their better optical control, fit into fixtures, and aesthetics. The maximum efficacy of a T5 lamp is slightly

TABLE 20.8.1 Characteristics and Applications of Typical 4-ft Fluorescent T8 Lamps

Lamp wattage	32W
Efficacy	For two 32W T8s and a single electronic ballast, ~90LPW
Rated lifetime	15,000–20,000 hours
Color Rendering Index	75–86
Color temperature	2700–5000 K
Lumen maintenance	Very good (light output typically declines by 10% to 12% over rated lamp life)
Optical controllability	Poor (very diffuse light)
Technologies for which these lamps are energy-efficient alternatives	These systems are most often replacements for less-efficient fluorescents (T12s with magnetic ballasts).

higher than that of a T8 lamp, and is achieved in ambient conditions that are about 10°C warmer than those optimal for T8 or T12 lamps. T8 and T5 high output (HO) lamps are also available for higher ceiling applications, but this application must be designed to prevent overheating the ballast. Eight-foot lamps have long been available in high output and very-high output (VHO) versions.

The specified or nominal wattage of a lamp refers to the power draw of the lamp alone. The ballast typically adds another 10% to 20% to the power draw, thus reducing system efficacy.

The most common efficient fluorescent lamp-ballast systems available today are T8 lamps operating with electronic ballasts. The characteristics and applications of 4-ft T8 lamps are summarized in Table 20.8.1. High performance T8 lamps are available with higher lumen output, longer rated lifetime, and higher lumen maintenance.

In spite of their much greater efficiency, fluorescent lamps have several disadvantages when compared to incandescent lamps. Standard fluorescent lamps can be dimmed, but require special dimming ballasts that cost more than the dimming controls used for incandescent lamps. Standard fluorescent lamps are larger than incandescent lamps of equivalent output and are harder to control optically. Fluorescent lamps (particularly instant start lamps) are not as economical in situations where they are switched on and off very frequently, as this shortens their life. Fluorescent lamps contain trace amounts of mercury, a toxic metal, and users of large quantities are required to either recycle them or dispose of them at designated facilities. However, mercury is also emitted in the production of electricity, and the net total emission of mercury, including the power plant emissions, is lower for fluorescent lamps than for the incandescent lamps that they replace. Fluorescent lamps also emit more UV light than incandescent lamps. UV light can cause colors to fade, and fabrics to age, and therefore has to be blocked near sensitive materials such as museum displays. Magnetic ballasts and more rarely electronic ballasts, are sometimes noisy and may emit radio interference. Electronic ballasts may interfere with security equipment, such as that used in libraries, and with specialized hospital devices.

Circular fluorescent lamps in 20- to 40-W sizes have been available for many years, but have had a fairly small market. Essentially, a circular lamp is a standard fluorescent lamp tube (as described earlier) that has been bent into a circle. Although they have a more compact geometry than a straight tube, circular lamps are still moderately large (16.5 to 41 cm [6.5 to 16.1 in.] in diameter). Circular lamps are available in several sizes with magnetic or electronic ballasts.

Compact fluorescent lamps (CFLs), which are substantially smaller than standard fluorescent lamps, were introduced to the U.S. market in the early 1980s. In a CFL, the lamp tube is smaller in diameter and is bent into sections. CFLs have much higher power densities per phosphor area than standard fluorescents, and their design was therefore dependent on the development of rare-earth phosphors, which could hold up much better than standard phosphors at high power loadings. CFLs (except for very low-wattage CFLs) are much more efficacious than the incandescent lamps they replace, typically drawing 1/3 to 1/4 of the wattage for similar light output. CFLs sold in the U.S. are also rated to last 9000–10,000 hours, with some newer products having even longer rated livetimes.

CFLs are available as both screw-in replacements for incandescent lamps and as pin-base lamps for hard-wired fixtures. Common CFLs range from 11 to 26 watts, and both higher and lower wattage lamps are available. They may be operated with separate ballasts or purchased as integral lamp/ballast units; integral units with electronic ballasts are the most commonly sold. The electronic ballast provides higher efficacy, eliminates the starting flicker, and has a lighter weight. CFLs have a much higher retail cost than the incandescent lamps they replace, and so consumers have been reluctant to purchase them without discounts or incentives; as they became more popular, their prices have decreased. CFL users in the residential sector encountered some limitations such as inability to dim, difficult fit in fixtures, starting in outdoor use, and overheating in enclosed fixtures. Manufacturers have developed lamps with smaller, more compatible shapes, and lamps that start at low outdoor temperatures; dimmable CFLs became available in the late 1990s. CFL reflector lamps are also available. In the commercial sector, dedicated fixtures with built-in ballasts are often used in downlights, to ensure that incandescents do not replace the CFLs.

Induction lamps are electrodeless fluorescent lamps that produce light by exciting phosphors coating the lamp. The radio frequency (RF) power supply sends an electric current to an induction coil, generating an electromagnetic field. This field excites the mercury in the gas fill, causing the mercury to emit ultraviolet (UV) energy. The UV energy strikes and excites the phosphor coating on the inside of the glass bulb, producing light. Electrodeless lamps have efficacies similar to those of CFLs or metal halide lamps of comparable light output. Electrodeless lamps use rare-earth phosphors, giving them color properties similar to those of higher-end fluorescent lamps. Because the lamp has no electrodes that usually cause lamp failure, the life of this system is determined by the induction coil. Induction lamps are rated at 100,000 hours of life. Because of this long life, and the good color rendition, induction technology has come into use for areas where maintenance to change the lamp is expensive, such as high ceilings in commercial and industrial buildings, atria, tunnels, and roadway sign lighting.

Induction lamps are electronic devices, and like all electronic devices they may generate electromagnetic interference (EMI) if unwanted electromagnetic signals, which can travel through wiring or radiate through the air, interfere with desirable signals from other devices. Shielding of the system to protect people and equipment from these emissions is important. Manufacturers must comply with Federal Communications Commission (FCC) regulations on EMI to sell products in the U.S.

High-intensity discharge (HD) lamps produce light by discharging an electrical arc through a mixture of gases. In contrast to fluorescent lamps, HID lamps use a compact arc tube in which both temperature and pressure are very high. In contrast to a fluorescent lamp, the arc tube in an HID lamp is small enough to permit compact reflector designs with good light control. There are currently three common types of HID lamps available: mercury vapor (MV), metal halide (MH), and high-pressure sodium (HPS). Additionally, low-pressure sodium (LPS) lamps, while not technically HID lamps, are used in some of the same applications as HPS lamps.

Because of their higher light output levels, HID lamps are most often used for exterior applications such as street and roadway lighting, outdoor area pedestrian and parking lot lighting, commercial, industrial, and residential floodlighting and security lighting, and sports lighting. They are also used in large, high-ceilinged, interior spaces such as industrial facilities and warehouses, where good color rendering is not typically a priority. HID lamps are sometimes used for indirect lighting in commercial offices, retail stores, and lobbies. Interior residential applications are rare because of high cost, lower CRI, and high light level. Also, HID lamps take several minutes to warm up to full light output, and if they are turned off or there is a momentary power outage, the lamps must cool down before they will restrike. Some HID lamps are now available with dual arc tubes or parallel filaments. Dual arc tubes eliminate the restrike problem and a parallel filament gives instantaneous light output both initially and on restrike, but at a cost of a high initial power draw and higher lamp cost.

The *mercury vapor (MV) lamp* was the first HID lamp developed. Including ballast losses, the efficacies of MV lamps range from approximately 25 to 50 LPW. Uncoated lamps have a bluish tint and very poor color rendering (CRI ~ 15). Phosphor-coated lamps emit more red but are still bluish, and have a CRI of about 50. Because of their poor color rendition, these lamps are used only where good color is not a priority. MV lamps generally have rated lifetimes in excess of 24,000 hours. Both metal halide (MH) and high-pressure sodium (HPS) HID lamps have higher efficacies than MV lamps and have consequently replaced them in most markets. MV lamps and ballasts are cheaper than the other HID sources and are still often sold as residential security lights. They also persist in some street lighting applications, landscape lighting, and in some other older systems.

Including ballast losses, *metal halide lamps* range in efficacy from 45 to 100 LPW. They produce white light and have CRIs ranging from 65 to almost 90. Lamp lifetimes generally range from only 5,000 to 20,000 hours, depending on the type of MH lamp. Lower-wattage MH lamps (particularly 50-W, 70-W, and 100-W) are now available with CRIs of about 65 to 75 and color temperatures of 2900 to 4200 K. Reasonably good lumen maintenance, longer life, and reduced maintenance costs, along with the fact that they blend more naturally with fluorescent sources, have made MH lamps a very good replacement in the commercial sector for 300-W and 500-W PAR lamps. New fixtures utilizing these lamps, particularly 1-ft by 1-ft recessed lensed troffers (downlights), are becoming common in lobbies, shopping malls, and retail stores. Improvements in color stability have made MH systems cost-effective substitutions for high-wattage incandescent lighting in commercial applications.

Including ballast losses, *high-pressure sodium lamps* have efficacies ranging from 45 LPW for the smallest lamps to 130 LPW for the largest lamps. Standard high-pressure sodium (HPS) lamps emit a yellow-orange light and have poor color rendition in the 20s; high-color rendering versions can have CRIs up to 70 and higher. Like MV lamps, HPS lamps are used only where good color is not a priority. HPS lamps have come to dominate street and roadway lighting because of their high efficacy and long life. The rated lifetimes of HPS lamps rival those of MV lamps and typically exceed 24,000 hours.

Metal halide technology is also becoming increasing popular for outdoor lighting, especially in areas where color rendering is important, and because of people's preference for "white light." Pulse-start technology is improving MH lamp performance in almost every aspect. In MH pulse start lamps, a high-voltage pulse (typically 3 kV minimum) applied directly across the main electrodes initiates the arc. Ignitors are used to provide these starting pulses. The average lifetime of pulse-start MH lamps now approaches that of HPS and MV lamps. With the higher efficacy this technology provides, approaching that of HPS lamps, pulse-start MH lamps now compete with HPS lamps in many outdoor applications. Ceramic arc tube MH lamps, with CRIs as high as 90 and better color consistency, now compete with incandescent sources. MH lamps may fail "non-passively," so users should always follow the manufacturers recommended practices for safe operation of the lamps.

At low light levels, such as those found in many outdoor areas at night, the eye's peripheral vision becomes more sensitive to light that is bluish. Although MH lamps are less efficacious than HPS lamps at high, or "photopic" light levels found during daylight hours, they can actually provide higher visual quality and therefore allow lower light levels, making them more efficacious, at least for peripheral vision, than HPS lamps at low or "scotopic" levels. This has led to increased interest in their use for street lighting.

Low-pressure sodium (LPS) lamps are discharge lamps that operate at lower arc tube loading pressure than do HID lamps. LPS lamps are monochromatic in the yellow spectral band and have CRIs of 0. They have been used for street and tunnel lighting, especially in cities near astronomical observatories, because the LPS color spectrum can easily be filtered out so as not to interfere with telescopes. (In more current efforts to limit "sky glow" as well as glare from outdoor lighting, the emphasis has shifted from lamp types to luminaire light control, with various levels of "cut-off" luminaires directing light downward and not upward, or using shielding to the same effect. For street lighting, calculations suggest that the match of the luminaire light distribution to the street, rather than the cut-off classification, is the most critical factor in limiting sky glow.) The LPS lamp has limitations for many applications where color rendering is important for safety and for identification.

Light-emitting diodes (LEDs) have had recent design advances in color and efficacy and are used in a number of specialty applications. Their advantages are small size, high directional intensities, long life (10,000 to 100,000 hours), and high reliability and durability. The major disadvantages of LEDs at this time are their limited output in lumens per device, their high cost per lumen, their relatively poor color rendering when used as a "white" source, and their relatively low efficacy (15–20 LPW for white light, 15–40 LPW for colors). However, the technology for LEDs is changing rapidly. Efficacies as high as 100 LPW have reported in the laboratory. Light output per device of 10 lumens is attainable now and target values of 100 lumens are projected for the next few years (a standard 60-W incandescent lamp produces about 900 lumens). Research on using organic materials to produce light (OLEDs) is also under way. LEDs have become widely used for traffic lights, exit signs and emergency lights, bicycle warning lights, and in applications where optical control is critical.

Ballasts

Because both fluorescent and HID lamps (discharge lamps) have a low resistance to the flow of electric current once the discharge arc is struck, they require a device to limit current flow. A lamp ballast is an electrical device used to control the current provided to the lamp. In most discharge lamps, a ballast also provides the high voltage necessary to start the lamp. Older preheat fluorescent lamps require a separate starter, but these lamps are becoming increasingly uncommon. In many HID ballasts, the ignitor used for starting the lamp is a replaceable module.

The most common types of fluorescent ballasts are magnetic core-coil and electronic high-frequency ballasts. A *magnetic core-coil ballast* uses a transformer with a magnetic core coiled in copper or aluminum wire to control the current provided to a lamp. Magnetic ballasts operate in the U.S. at the standard AC input frequency of 60 Hz and operate lamps at the same 60 Hz. An *electronic high-frequency ballast* uses electronic circuitry rather than magnetic components to control current. Electronic ballasts use standard 60 Hz power but operate lamps at a much higher frequency (20,000 to 60,000 Hz). Both magnetic and electronic ballasts are available for most fluorescent lamp types.

The *cathode cut-out (hybrid) ballast* is a modified fluorescent magnetic ballast. It uses an electronic circuit to remove the filament power after the discharge has been initiated for rapid-start lamps. Cathode cutout ballasts use approximately 5% to 10% less energy than magnetic ballasts.

Of the ballasts that are currently available for fluorescent lamps, the most efficient option is the electronic ballast. Because an electronic ballast is more efficient than a standard core-coil magnetic ballast in transforming the input power to lamp requirements, and because fluorescent lamps are more efficient when operated at frequencies of 20,000 Hz or more, a lamp/ballast system using an electronic rather than magnetic ballast is more efficacious. T8 lamps can be operated on conventional magnetic ballasts although they are most commonly used with high-frequency electronic ballasts. Operation with electronic ballasts increases the lamp efficacy by about 9% over operation with magnetic ballasts. TS lamps operate exclusively with electronic ballasts.

In addition, electronic ballasts eliminate flicker, weigh less than magnetic ballasts, and operate more quietly. Since electronic ballasts are packaged in cans that are the same size as magnetic ballasts, they can be placed in the same fixtures designed to be used with magnetic ballasts. Fluorescent electronic ballasts are available for standard commercial-sector applications. They have become increasingly popular, particularly in new luminaires as well as in energy-efficiency retrofits. Advances in dimming fluorescent ballasts allow further energy savings through automatic controls.

The upcoming U.S. fluorescent ballast standards essentially require all ballasts driving T12 fluorescent lamps sold in luminaires to be electronic by 2006 and T12 ballasts sold separately (replacement ballasts) to be electronic beginning in 2010.

Most cathode cutout ballasts will not meet the new ballast standards. End users who cannot use electronic fluorescent ballasts for technical reasons (primarily electronic interference with specialized equipment) may use T8 lamps with magnetic ballasts.

The most commonly used ballasts for HID lamps are magnetic, and a number of different types are available. The various types differ primarily in how well they tolerate voltage swings and, in the case of HPS lamps, the increased voltage required to operate the lamp as it ages. Electronic ballasts are also available, although the energy savings are less than for fluorescent systems. As with fluorescent systems, HID electronic ballasts provide flicker-free lighting and regulate lamp power, which increases lamp life and maintains constant color.

Lighting Fixtures

A lighting fixture is a housing for securing lamp(s) and ballast(s) and for controlling light distribution to a specific area. The function of the fixture is to distribute light to the desired area without causing glare or discomfort. The distribution of light is determined by the geometric design of the fixture as well as the material of which the reflector and/or lens is made. The more efficient a fixture is, the more light it emits from the lamp(s) within it. Although the term *luminaire* is sometimes used interchangeably with *fixture, luminaire* refers to a complete lighting system, including the lamps and fixture (which includes the ballast/s).

Types of fluorescent lighting fixtures that are commonly used in the non-residential sectors include recessed troffers, pendant-mounted indirect and indirect/direct fixtures, and surface-mounted fixtures such as wraparound, strip, and industrial fixtures.

Until recently, most offices have been equipped with *recessed troffers*, which are direct (light emitted downward) fixtures and emphasize horizontal surfaces. Many forms of optical control are possible with recessed luminaires. In the past, prismatic lenses were the preferred optical control because they offer high luminaire efficiency and uniform illuminance in the work space.

Offices with electronic equipment have become increasingly common, however, and until fairly recently there was a trend away from the traditional direct lighting fixtures designed for typing and other horizontal tasks because they tend to cause reflections on video display terminal (VDT) screens. No lighting system reduces glare entirely, but some fixtures and/or components can reduce the amount of glare significantly. *Parabolic louvered fixtures* have come into use in office spaces. These fixtures have reflectors in the form of louvers, often aluminized, with parabolic geometry that directs light downward. Because the glossy, vertical VDT screen can potentially reflect bright spots on the ceiling, and because VDT work is usually done with the head up, existing fixtures are also sometimes replaced with indirect or direct/indirect fixtures, which produce light that is considered more visually comfortable. Most indirect lighting systems are suspended from the ceiling. They direct light toward the ceiling, where the light is then reflected downward to provide a calm, diffuse light. Some people describe the indirect lighting as similar to the light on an overcast day, with no shadows or highlights. Generally, indirect lighting does not cause bright reflections on VDT screens. A *direct/indirect fixture* is suspended from the ceiling and provides direct light as well as indirect. These fixtures combine the high efficiency of direct lighting systems with the uniformity of light and lack of glare produced by indirect lighting systems. New, flat-panel liquid crystal display monitors are much less sensitive to reflections than the older cathode-ray tube VDTs, and this may affect the types of fixtures used in offices in the future.

A *wraparound fixture* has a prismatic lens that wraps around the bottom and sides of the lamp, and is always surface mounted rather than recessed. Wraparound fixtures are less expensive than other commercial fixtures and are typically used in areas where lighting control and distribution are not a priority. *Strip* and *industrial fixtures* are even less expensive and are typically used in places where light distribution is less important, such as large open areas (grocery stores, for example) and hallways. These are open fixtures in which the lamp is not hidden from view.

The most common incandescent fixture in the nonresidential sector is the *downlight*, also known as a recessed can fixture. Fixtures designed for CFLs are available to replace incandescent downlight fixtures in areas where lighting control is less critical.

Interior HID fixtures include high-bay and low-bay fixtures (aisle lighters and parking garages, etc.), downlights, and accent lighting. Exterior HID fixtures include street and roadway fixtures (cobrahead, post-top, architectural), floods of all sizes and types (from sports to landscape), wall-mounted, and security fixtures.

Luminaire efficacy rating (LER) is a single metric that expresses *luminaire efficacy*, the luminaire's light output divided by the input power. The formula for fluorescent luminaires is

$$\mathrm{LER} = \frac{\mathrm{LuminaireEfficiency(EFF)}^{*}\mathrm{TotalRatedLampLumens(TLL)}^{*}\mathrm{BallastFactor(BF)}}{\mathrm{LuminaireWattsInput}}$$

Note that the effects of all components of the luminaire system (lamp, ballast, and fixture) are included in the LER. The National Electrical Manufacturers Association (NEMA) Standards Publication No. LE5, "Procedure for Determining Luminaire Efficacy Ratings for Fluorescent Luminaires," specifies the major fluorescent luminaire categories covered and the standard industry test procedures. NEMA's LE5A and LE5B give the procedures for commercial downlight luminaires and HID industrial luminaires.

Increasing Lighting Efficiency

Many existing lighting systems are equipped with relatively inefficient lamps and ballasts. Depending on the age and condition of the fixture, it may be cost-effective to either replace the luminaire or replace the existing lamps and ballasts (retrofit) with more efficient equipment. Care should always be taken to ensure that any changes to a lighting system will improve the quality of lighting as well as the economics. State-of-the-art lighting equipment is now synonymous with energy efficiency and lighting quality.

For more information on retrofitting existing lighting systems with more efficient equipment, refer the Illuminating Engineering Society of North America's LEM-3-04, "IESNA Guidelines for Retrofitting Lighting Systems in Commercial and Institutional Spaces" (see References).

Defining Terms

Ballast: An electrical device used to control the current provided to the lamp. In most discharge lamps, a ballast also provides the high voltage necessary to start the lamp.

Ballast factor: The fractional (luminous) flux of a fluorescent lamp operated on a ballast compared to the flux when operated on the standard (reference) ballast specified for rating lamp lumens.

Color Rendering Index (CRI): A measure of how surface colors appear when illuminated by a lamp compared to how they appear when illuminated by a reference source of the same color temperature. For color temperature above 5000 K, the reference source is a standard daylight condition of the same color temperature; below 5000 K, the reference source is a blackbody radiator.

Color temperature: The color of a lamp's light is described by its color temperature, expressed in degrees Kelvin (K). The concept of color temperature is based on the fact that the emitted radiation spectrum of a blackbody radiator depends on temperature alone. The color temperature of a lamp is the temperature at which an ideal blackbody radiator would emit light that is the same color as the light of the lamp.

Efficacy: The ratio of the amount of light emitted (lumens) to the power (watts) drawn by a lighting system. The unit used to express efficacy is lumens per watt (LPW). Efficacy may be expressed as *lamp efficacy*, using the nominal wattage of the lamp, or as *system efficacy*, using the system watts that include the ballast losses.

Lumen maintenance: The extent to which a lamp sustains its lumen output (and therefore efficacy) over time.

Appendix A. Properties of Gases and Vapors

TABLE A.1 Properties of Dry Air at Atmospheric Pressure

Symbols and Units:

K = absolute temperature, degrees Kelvin
deg C = temperature, degrees Celsius
deg F = temperature, degrees Fahrenheit
ρ = density, kg/m^3
c_p = specific heat capacity, kJ/kg·K
c_p/c_v = specific heat capacity ratio, dimensionless
μ = viscosity, N·s/m^2 × 10^6 (For N·s/m^2 (= kg/m·s) multiply tabulated values by 10^{-6})
k = thermal conductivity, W/m·k × 10^3 (For W/m·K multiply tabulated values by 10^{-3})
Pr = Prandtl number, dimensionless
h = enthalpy, kJ/kg
V_s = sound velocity, m/s

TABLE A.2 Ideal Gas Properties of Nitrogen, Oxygen, and Carbon Dioxide

Symbols and Units:

T = absolute temperature, degrees Kelvin
$\bar{h}$ = enthalpy, kJ/kmol
$\bar{u}$ = internal energy, kJ/kmol
$\bar{s}^\circ$ = absolute entropy at standard reference pressure, kJ/kmol K
[$\bar{h}$ = enthalpy of formation per mole at standard state = 0 kJ/kmol]

Part a. Ideal Gas Properties of Nitrogen, N_2

TABLE A.3 Psychrometric Table: Properties of Moist Air at 101 325 N/m^2

Symbols and Units:

P_s = pressure of water vapor at saturation, N/m^2
W_s = humidity ratio at saturation, mass of water vapor associated with unit mass of dry air
V_a = specific volume of dry air, m^3/kg
V_s = specific volume of saturated mixture, m^3/kg dry air

h_a^a = specific enthalpy of dry air, kJ/kg
h_s = specific enthalpy of saturated mixture, kJ/kg dry air
s_s = specific entropy of saturated mixture, J/K·kg dry air

Note: The P_s column in this table gives the vapor pressure of pure water at temperature intervals of five degrees Celsius. For the latest data on vapor pressures at intervals of 0.1 deg C, from 0–100 deg C, see "Vapor Pressure Equation for Water", A. Wexler and L. Greenspan, *J. Res. Nat. Bur. Stand.*, 75A(3):213–229, May–June 1971.

[a] For very low barometric pressures and high wet-bulb temperatures, the values of h_a in this table are somewhat low; for corrections see "ASHRAE Handbook of Fundamentals".

* Computed from: Psychrometric Tables, in "ASHRAE Handbook of Fundamentals", American Society of Heating, Refrigerating and Air-Conditioning Engineers, 1972.

TABLE A.4 Water Vapor at Low Pressures: Perfect Gas Behavior pv/T = R = 0.461 51 kJ/kg·K

Symbols and Units:

t = thermodynamic temperature, deg C
T = thermodynamic temperature, K
pv = RT, kJ/kg
u_o = specific internal energy at zero pressure, kJ/kg
h_o = specific enthalpy at zero pressure, kJ/kg
s_l = specific entropy of semiperfect vapor at 0.1 MN/m^2, kJ/kg·K
ψ_l = specific Helmholtz free energy of semiperfect vapor at 0.1 MN/m^2, kJ/kg
ψ_l = specific Helmholtz free energy of semiperfect vapor at 0.1 MN/m^2, kJ/kg
ζ_l = specific Gibbs free energy of semiperfect vapor at 0.1 MN/m^2, kJ/kg
p_r = relative pressure, pressure of semiperfect vapor at zero entropy, TN/m^2
v_r = relative specific volume, specific volume of semiperfect vapor at zero entropy, mm^3/kg
c_{po} = specific heat capacity at constant pressure for zero pressure, kJ/kg·K
c_{vo} = specific heat capacity at constant volume for zero pressure, kJ/kg·K
$k = c_{po}/c_{vo}$ = isentropic exponent, $-(\partial \log p/\partial \log v)_s$

TABLE A.7 Chemical, Physical, and Thermal Properties of Gases: Gases and Vapors, Including Fuels and Refrigerants, English and Metric Units

Common name(s)	*Acetylene (Ethyne)*	*Air [mixture]*	*Ammonia, anhyd.*	*Argon*
Chemical formula	C_2H_2		NH_3	*Ar*
Refrigerant number	—	*729*	*717*	*740*
CHEMICAL AND PHYSICAL PROPERTIES				
Molecular weight	26.04	28.966	17.02	39.948
Specific gravity, air = 1	0.90	1.00	0.59	1.38
Specific volume, ft³/lb	14.9	13.5	23.0	9.80
Specific volume, m³/kg	0.93	0.842	1.43	0.622
Density of liquid (at atm bp), lb/ft³	43.0	54.6	42.6	87.0
Density of liquid (at atm bp), kg/m³	693.	879.	686.	1 400.
Vapor pressure at 25 deg C, psia			145.4	
Vapor pressure at 25 deg C, MN/m²			1.00	
Viscosity (abs), lbm/ft·sec	6.72×10^{-6}	12.1×10^{-6}	6.72×10^{-6}	13.4×10^{-6}
Viscosity (abs), centipoises[a]	0.01	0.018	0.010	0.02
Sound velocity in gas, m/sec	343	346	415	322
THERMAL AND THERMODYNAMIC PROPERTIES				
Specific heat, c_p, Btu/lb·deg F or cal/g·deg C	0.40	0.240 3	0.52	0.125
Specific heat, c_p, J/kg·K	1 674.	1 005.	2 175.	523.
Specific heat ratio, c_p/c_v	1.25	1.40	1.3	1.67
Gas constant *R*, ft-lb/lb·deg R	59.3	53.3	90.8	38.7
Gas constant *R*, J/kg·deg C	319	286.8	488.	208.
Thermal conductivity, Btu/hr·ft·deg F	0.014	0.015 1	0.015	0.010 2
Thermal conductivity, W/m·deg C	0.024	0.026	0.026	0.017 2
Boiling point (sat 14.7 psia), deg F	−103	−320	−28.	−303.
Boiling point (sat 760 mm), deg C	−75	−195	−33.3	−186
Latent heat of evap (at bp), Btu/lb	264	88.2	589.3	70.
Latent heat of evap (at bp), J/kg	614 000	205 000.	1 373 000	163 000
Freezing (melting) point, deg F (1 atm)	−116	−357.2	−107.9	−308.5
Freezing (melting) point, deg C (1 atm)	−82.2	−216.2	−77.7	−189.2
Latent heat of fusion, Btu/lb	23.	10.0	143.0	
Latent heat of fusion, J/kg	53 500	23 200	332 300	
Critical temperature, deg F	97.1	−220.5	271.4	−187.6
Critical temperature, deg C	36.2	−140.3	132.5	−122
Critical pressure, psia	907.	550.	1 650.	707.
Critical pressure, MN/m²	6.25	3.8	11.4	4.87
Critical volume, ft³/lb		0.050	0.068	0.029 9
Critical volume, m³/kg		0.003	0.004 24	0.001 86
Flammable (yes or no)	Yes	No	No	No
Heat of combustion, Btu/ft³	1 450	—	—	—
Heat of combustion, Btu/lb	21 600	—		
Heat of combustion, kJ/kg	50 200	—	—	—

[a] For N·sec/m² divide by 1 000.

Note: The properties of pure gases are given at 25°C (77°F, 298 K) and atmospheric pressure (except as stated).

TABLE A.7 (continued) Chemical, Physical, and Thermal Properties of Gases: Gases and Vapors, Including Fuels and Refrigerants, English and Metric Units

Common name(s)	*Butadiene*	*n-Butane*	*Isobutane (2-Methyl propane)*	*1-Butene (Butylene)*
Chemical formula	C_4H_6	C_4H_{10}	C_4H_{10}	C_4H_8
Refrigerant number	—	*600*	*600a*	—
CHEMICAL AND PHYSICAL PROPERTIES

Flammable (yes or no)	Yes	Yes	Yes	No
Heat of combustion, Btu/ft^3	3 150.	3 150.	3 150.	—
Heat of combustion, Btu/lb	21 000.	21 000.	21 000.	—
Heat of combustion, kJ/kg	48 800.	48 800.	48 800.	—

[a] For $N \cdot sec/m^2$ divide by 1 000.

[b] Sublimes.

TABLE A.7 (continued) Chemical, Physical, and Thermal Properties of Gases: Gases and Vapors, Including Fuels and Refrigerants, English and Metric Units

Common name(s)	*Carbon monoxide*	*Chlorine*	*Deuterium*	*Ethane*
Chemical formula	CO	Cl_2	D_2	C_2H_6
Refrigerant number	—	—	—	*170*
CHEMICAL AND PHYSICAL PROPERTIES				
Molecular weight	28.011	70.906	2.014	30.070
Specific gravity, air = 1	0.967	2.45	0.070	1.04
Specific volume, ft^3/lb	14.0	5.52	194.5	13.025
Specific volume, m^3/kg	0.874	0.344	12.12	0.815
Density of liquid (at atm bp), lb/ft^3		97.3		28.
Density of liquid (at atm bp), kg/m^3		1 559.		449.
Vapor pressure at 25 deg C, psia			0.756	
Vapor pressure at 25 deg C, MN/m^2			0.005 2	
Viscosity (abs), lbm/ft·sec	12.1×10^{-6}	9.4×10^{-6}	8.75×10^{-6}	$64. \times 10^{-6}$
Viscosity (abs), centipoises[a]	0.018	0.014	0.013	0.095
Sound velocity in gas, m/sec	352.	215.	930.	316.
THERMAL AND THERMODYNAMIC PROPERTIES				
Specific heat, c_p, Btu/lb·deg F or cal/g·deg C	0.25	0.114	1.73	0.41
Specific heat, c_p, J/kg·K	1 046.	477.	7 238.	1 715.
Specific heat ratio, c_p/c_v	1.40	1.35	1.40	1.20
Gas constant R, ft-lb/lb·deg F	55.2	21.8	384.	51.4
Gas constant R, J/kg·deg C	297.	117.	2 066.	276.
Thermal conductivity, Btu/hr·ft·deg F	0.014	0.005	0.081	0.010
Thermal conductivity, W/m·deg C	0.024	0.008 7	0.140	0.017
Boiling point (sat 14.7 psia), deg F	−312.7	−29.2		−127.
Boiling point (sat 760 mm), deg C	−191.5	−34.		−88.3
Latent heat of evap (at bp), Btu/lb	92.8	123.7		210.
Latent heat of evap (at bp), J/kg	216 000.	288 000.		488 000.
Freezing (melting) point, deg F (1 atm)	−337.	−150.		−278.
Freezing (melting) point, deg C (1 atm)	−205.	−101.		−172.2
Latent heat of fusion, Btu/lb	12.8	41.0		41.
Latent heat of fusion, J/kg		95 400.		95 300.
Critical temperature, deg F	−220.	291.	−390.6	90.1
Critical temperature, deg C	−140.	144.	−234.8	32.2
Critical pressure, psia	507.	1 120.	241.	709.
Critical pressure, MN/m^2	3.49	7.72	1.66	4.89
Critical volume, ft^3/lb	0.053	0.028	0.239	0.076
Critical volume, m^3/kg	0.003 3	0.001 75	0.014 9	0.004 7
Flammable (yes or no)	Yes	No		Yes
Heat of combustion, Btu/ft^3	310.	—		
Heat of combustion, Btu/lb	4 340.	—		22 300.
Heat of combustion, kJ/kg	10 100.	—		51 800.

[a] For N·sec/m^2 divide by 1 000.

TABLE A.7 (continued) Chemical, Physical, and Thermal Properties of Gases: Gases and Vapors, Including Fuels and Refrigerants, English and Metric Units

Common name(s)	*Ethyl chloride*	*Ethylene (Ethene)*	*Fluorine*
Chemical formula	C_2H_5Cl	C_2H_4	F_2
Refrigerant number	*160*	*1 150*	
CHEMICAL AND PHYSICAL PROPERTIES			
Molecular weight	64.515	28.054	37.996
Specific gravity, air = 1	2.23	0.969	1.31
Specific volume, ft^3/lb	6.07	13.9	10.31
Specific volume, m^3/kg	0.378	0.87	0.706
Density of liquid (at atm bp), lb/ft^3	56.5	35.5	
Density of liquid (at atm bp), kg/m^3	905.	569.	
Vapor pressure at 25 deg C, psia			
Vapor pressure at 25 deg C, MN/m^2			
Viscosity (abs), lbm/ft·sec		6.72×10^{-6}	16.1×10^{-6}
Viscosity (abs), centipoises[a]		0.010	0.024
Sound velocity in gas, m/sec	204.	331.	290.
THERMAL AND THERMODYNAMIC PROPERTIES			
Specific heat, c_p, Btu/lb·deg F or cal/g·deg C	0.27	0.37	0.198
Specific heat, c_p, J/kg·K	1 130.	1 548.	828.
Specific heat ratio, c_p/c_v	1.13	1.24	1.35
Gas constant R, ft-lb/lb·deg F	24.0	55.1	40.7
Gas constant R, J/kg·deg C	129.	296.	219.
Thermal conductivity, Btu/hr·ft·deg F		0.010	0.016
Thermal conductivity, W/m·deg C		0.017	0.028
Boiling point (sat 14.7 psia), deg F	54.	−155.	−306.4
Boiling point (sat 760 mm), deg C	12.2	−103.8	−188.
Latent heat of evap (at bp), Btu/lb	166.	208.	74.
Latent heat of evap (at bp), J/kg	386 000.	484 000.	172 000.
Freezing (melting) point, deg F (1 atm)	−218.	−272.	−364.
Freezing (melting) point, deg C (1 atm)	−138.9	−169.	−220.
Latent heat of fusion, Btu/lb	29.3	51.5	11.
Latent heat of fusion, J/kg	68 100.	120 000.	25 600.
Critical temperature, deg F	368.6	49.	−200
Critical temperature, deg C	187.	9.5	−129.
Critical pressure, psia	764.	741.	810.
Critical pressure, MN/m^2	5.27	5.11	5.58
Critical volume, ft^3/lb	0.049	0.073	
Critical volume, m^3/kg	0.003 06	0.004 6	
Flammable (yes or no)	No	Yes	
Heat of combustion, Btu/ft^3	—	1 480.	
Heat of combustion, Btu/lb	—	20 600.	
Heat of combustion, kJ/kg	—	47 800.	

[a] For N·sec/m^2 divide by 1 000.

TABLE A.7 (continued) Chemical, Physical, and Thermal Properties of Gases: Gases and Vapors, Including Fuels and Refrigerants, English and Metric Units

Common name(s)	*Fluorocarbons*			
Chemical formula	CCl_3F	CCl_2F_2	$CClF_3$	$CBrF_3$
Refrigerant number	*11*	*12*	*13*	*13B1*
CHEMICAL AND PHYSICAL PROPERTIES				
Molecular weight	137.37	120.91	104.46	148.91

TABLE B.1 Properties of Liquid Water*

Symbols and Units:

ρ = density, lbm/ft^3. For g/cm^3 multiply by 0.016018. For kg/m^3 multiply by 16.018.

c_p = specific heat, Btu/lbm·deg R = cal/g·K. For J/kg·K multiply by 4186.8

μ = viscosity. For lbf·sec/ft^2 = slugs/sec·ft, multiply by 10^{-7}. For lbm·sec·ft multiply by 10^{-7} and by 32.174. For g/sec·cm (poises) multiply by 10^{-7} and by 478.80. For N·sec/m^2 multiply by 10^{-7} and by 478.880.

k = thermal conductivity, Btu/hr·ft·deg R. For W/m·K multiply by 1.7307.

Temp, °F	At 1 atm or 14.7 psia				At 1,000 psia				At 10,000 psia

†At 7,500 psia.

*From: "1967 ASME Steam Tables", American Society of Mechanical Engineers, Tables 9, 10, and 11 and Figures 6, 7, 8, and 9.

The ASME compilation is a 330-page book of tables and charts, including a 2½ × 3½-ft Mollier chart. All values have been computed in accordance with the 1967 specifications of the International Formulation Committee (IFC) and are in conformity with the 1963 International Skeleton Tables. This standardization of tables began in 1921 and was extended through the International Conferences in London (1929), Berlin (1930), Washington (1934), Philadelphia (1954), London (1956), New York (1963) and Glasgow (1966). Based on these world-wide standard data, the 1967 ASME volume represents detailed computer output in both tabular and graphic form. Included are density and volume, enthalpy, entropy, specific heat, viscosity, thermal conductivity, Prandtl number, isentropic exponent, choking velocity, p-v product, etc., over the entire range (to 1500 psia 1500°F). English units are used, but all conversion factors are given.

TABLE B.2 Physical and Thermal Properties of Common Liquids

Part a. SI Units

(At 1.0 Atm Pressure (0.101 325 MN/m^2), 300 K, except as noted.)

Common name	*Density, kg/m^3*	*Specific heat, kJ/kg·K*	*Viscosity, N·s/m^2*	*Thermal conductivity, W/m·K*	*Freezing point, K*	*Latent heat of fusion, kJ/kg*	*Boiling point, K*	*Latent heat of evaporation, kJ/kg*	*Coefficient of cubical expansion per K*

†Some values reported as low as 1.6

*Based largely on: "Smithsonian Physical Tables", 9th rev. ed., W.E. Forsythe, Ed., The Smithsonian Institution, 1956, p. 292.

Note: In the case of substances with voids, such as paper or leather, the bulk density is indicated rather than the density of the solid portion. For density in kg/m^3, multiply values in g/cm^3 by 1,000.

TABLE C.3 Specific Stiffness of Metals, Alloys, and Certain Non-Metallics*

Specific stiffness is usually expressed as the modulus of elasticity (in tension) per unit weight-density, i.e., E/ρ, in units of pounds and inches. While the stiffness of similar alloys varies considerably, there are definite ranges and groups to be recognized. Since the specific stiffness of steel is about 100 million, the values in the following table are also approximately the percentage stiffness, referred to steel.

Material	*Specific stiffness, millions*
Beryllium	650
Silicon carbide	600
Alumina ceramics	400
Mica	350
Titanium carbide cermet	250
Alumina cermet	200
Molybdenum and alloys; silica glass	130

** To convert to SI units note that l cal = 4.186 J.

TABLE C.5 Mechanical Properties of Metals and Alloys:* Typical Composition, Properties, and Uses of Common Materials

For MN/m^2 multiply strength in thousands of psi by 6.895.

FERROUS ALLOYS

Ferrous alloys comprise the largest volume of metal alloys used in engineering. The actual range of mechanical properties in any particular grade of alloy steel depends on the particular history and heat treatment. The steels listed in this table are intended to give some idea of the range of properties readily obtainable. Many hundreds of steels are available. Cost is frequently an important criterion in the choice of material; in general the greater the percentage of alloying elements present in the alloy, the greater will be the cost.

No.	*Material*	*Nominal composition*	*Form and condition*	*Typical mechanical properties*				*Comments*
				Yield strength (0.2% offset), 1000 lb/sq in.	*Tensile strength, 1000 lb/sq in.*	*Elongation, in 2 in., %*	*Hardness, Brinell*

TABLE C.5 (continued) Mechanical Properties of Metals and Alloys:* Typical Composition, Properties, and Uses of Common Materials

CAST IRONS AND CAST STEELS

These alloys are used where large and/or intricate-shaped articles are required or where over-all dimensional tolerances are not critical. Thus the article can be produced with the fabrication and machining costs held to a minimum. Except for a few heat-treatable cast steels, this class of alloys does not demonstrate high-strength qualities.

SUPER ALLOYS

The advent of engineering applications requiring high temperature and high strength, as in jet engines and rocket motors, has lead to the development of a range of alloys collectively called super alloys. These alloys require excellent resistance to oxidation together with strength at high temperatures, typically 1800°F in existing engines. These alloys are continually being modified to develop better specific properties, and therefore entries in this group of alloys should be considered "fluid". Both wrought and casting-type alloys are represented. As the high temperature properties of cast materials improve, these alloys become more attractive, since great dimensional precision is now attainable in investment castings.

ALUMINUM ALLOYS

Although the strength of aluminum alloys is in general less than that attainable in ferrous alloys or copper-base alloys, their major advantage lies in their high strength-to-weight ratio due to the low density of aluminum. Aluminum alloys have good corrosion resistance for most applications except in alkaline solutions.

No.	Material	Nominal composition	Form and condition	Typical mechanical properties: Yield strength (0.2% offset), 1000 lb/sq in.	Tensile strength, 1000 lb/sq in.	Elongation, in 2 in., %	Hardness, Brinell	Comments

COPPER ALLOYS

Because of their corrosion resistance and the fact that copper alloys have been used for many thousands of years, the number of copper alloys available is second only to the ferrous alloys. In general copper alloys do not have the high-strength qualities of the ferrous alloys, while their density is comparable. The cost per strength-weight ratio is high; however, they have the advantage of ease of joining by soldering, which is not shared by other metals that have reasonable corrosion resistance.

81	Solder	Sn 20.0 Pb 80.0	Cast	3.6	5.8	16	11	Coating and joining, filling seams on automobile bodies

MAGNESIUM ALLOYS

Because of their low density these alloys are attractive for use where weight is at a premium. The major drawback to the use of these alloys is their ability to ignite in air (this can be a problem in machining); they are also costly. Magnesium alloys are used in both the wrought and die-cast forms, the latter being the most frequently used form.

No.	Material	Nominal composition	Form and condition	Yield strength (0.2% offset), 1000 lb/sq in.	Tensile strength, 1000 lb/sq in.	Elongation, in 2 in., %	Hardness, Brinell	Comments

*Compiled from several sources.

TABLE C.7 Composition and Melting Points of Binary Eutectic Alloys:* Binary Alloys and Solid Solutions of Metallic Components

This table represents most of the common binary combinations of metals. For many pairs no eutectic exists; for many others the information is uncertain or unavailable. In a fair number of cases, there is complete mutual solubility in all proportions; hence, there is a smooth temperature vs. composition curve, with no point of inflection from the melting point of one constituent to that of the other. For purposes of comparison, all values must be considered approximate in view of the experimental difficulties and the many sources of data.

Those pairs for which the liquidus curve exhibits more than one cusp are designated by a superscript *a*. In a few cases the cusp selected for this table does not represent the lowest possible melting point for the binary mixture.

*The data in this table are compiled from various sources—hence the variations in the melting point of the metals as shown in this column.

**Based largely on: "Smithsonian Physical Tables", 9th rev. ed., W.E. Forsythe, Ed., The Smithsonian Institution, 1956.

TABLE C.9 Trade Names, Composition, and Manufacturers of Various Plastics

Trade name	*Composition*	*Manufacturer*
Abson	Acrylonitrile-butadiene, ABS polymers	B. F. Goodrich Chemical Co.
Alathon	Polyethylene resins	E. I. du Pont de Nemours & Co., Inc.
Alkor	Furane resin cement	Atlas Minerals & Chemicals Div., The Electric Storage Battery Co.
Amres	Phenolics, urea, and melamine resins	American Marietta Co., Pacific Resins & Chemicals, Inc.
Araldite	Epoxy resins	CIBA Products Co., Div. CIBA Corp.
Atlac	Polyester resins	Atlas Chemical Industries, Inc.
Bakelite	Acrylics, epoxies, phenolics, polyethylenes, copolymers	Union Carbide Corp., Chemicals and Plastics Div.
Bavick-11	Methyl methacrylate and methylstyrene copolymer	J. T. Baker Chemical Co.
Boltaflex	Supported and unsupported flexible vinyl sheeting	The General Tire & Rubber Co.
Boltaron	Rigid polyvinyl chloride sheet	The General Tire & Rubber Co., Chemical & Plastics Div.
Butacite	Polyvinyl butyral resins	E. I. du Pont de Nemours & Co., Inc.
Conolite	Polyester resins and laminates	Shellmar-Betner, Div. Continental Can Co. Woodall Industries, Inc., Conolite Div.
Corvel	Epoxies, vinyls Fusion-bond finishes	The Polymer Corp., Export-Polypenco Div.
Cumar	Paracoumarone-indene resins	Allied Chemical Corp., Plastics Div.
Cycolac	ABS polymers, acrylonitrile-butadiene-styrene copolymers	Marbon Chemical Div., Borg-Warner Corporation
Dacovin	Polyvinyl chlorides	Diamond Shamrock Corp.
Dapon	Diallyl phthalate resins	FMC Corp., Organic Div.
Delrin	Acetal resin and pipe	E. I. du Pont de Nemours & Co., Inc.
Dylan	Polyethylene	Sinclair-Koppers Co.
Dylene	Polystyrene	Sinclair-Koppers Co.
Dylite	Expandable polystyrene	Sinclair-Koppers Co.
Epi-Rez	Epoxy resins	Celanese Coatings Co., Celanese Resin Div.
Epolene	Low molecular-weight polyethylene resins	Eastman Chemical Products, Inc., Sub. Eastman Kodak Company
Epoxical	Epoxy resins	United States Gypsum Co.
Epon	Epoxy resins and curing agents	The Shell Chemical Company, Plastics and Resins Div.
Escon	Polypropylene resins	Enjay Chemical Co., Div. Humble Oil & Refining Company
Estane	Polyurethane materials	B. F. Goodrich Chemical Company
Fluorogreen	Teflon with glass and ceramic fibers, fluorocarbons	John L. Dore Co.
Fluororay	Ceramic-filled fluorocarbons	Raybestos-Manhattan, Inc., Plastic Products Div.
Formica	Melamines	Formica Corp. of American Cyanamid
Forticel	Cellulose propionate sheet films, molding powders	Celanese Plastics Co.
Fortiflex	Polyethylene resins	Celanese Plastics Co.
Fosta-Tuf-Flex	Polystyrene, high-impact	Foster-Grant, Inc.
Furnane	Furanes	Atlas Minerals & Chemicals Div., The Electric Storage Battery Co.
GenEpoxy	Epoxy resins for adhesives, coatings, etc.	General Mills, Inc., Chemical Div.
Genetron	Fluorinated hydrocarbons, monomers, and polymers	Allied Chemical Corp., General Chemical Div.
Geon	Polyvinyl chloride materials	B. F. Goodrich Chemical Co.
Grex	High-density polyethylenes	Allied Chemical Corp., Plastics Div.
Halon	Fluorohalocarbon resins	Allied Chemical Corp.
Hetron	Fire-retardant polyester resin	Hooker Chemical Corp., Durez Plastics Div.
Isothane	Polyurethane foam, ester, and ether	Bernel Foam Products Co., Inc.
Kel-F	Chlorotrifluoroethylene, molding resins, and dispersions	3M Company
Kralac	High-styrene resins, styrene-butadiene copolymers	Uniroyal Chemical, Div. of Uniroyal Inc.
Kralastic	ABS polymers, copolymers	Uniroyal Chemical, Div. of Uniroyal Inc.
Kynar	Polyvinylidene fluoride	Pennsalt Chemical Corp.
Lexan	Polycarbonate resin, film, and sheet	General Electric Company, Plastics Dept.
Lucite	Acrylic resin and syrup	E. I. du Pont de Nemours & Co., Inc.
Lustran	ABS polymers	Monsanto Co.
Lustrex	Styrene molding and extrusion resins	Monsanto Co.
Lytron	Styrene molding and extrusion resins	Monsanto Co.
Madurit	Melamine resins and compounds	Cassella Farbwerke Mainkur, A.G.
Maraglas	Epoxy-casting resin	The Marblette Corporation, Div. of Allied Products
Marlex	Polyethylenes, polypropylenes, copolymers	Phillips Petroleum Co.
Marvinol	Vinyl chloride resins and compounds	Uniroyal Chemical, Div. of Uniroyal Inc.
Merlon	Polycarbonate resins	Mobay Chemical Co.
Micarta	Melamines, phenolics, polyesters	Westinghouse Electric Co., Industrial Micarta Div.
Microthene	Polyethylenes, polyolefins	U.S. Industrial Chemicals Co.
Multrathane	Urethane elastomers	Mobay Chemical Company
Nopcofoam	Polyurethane plastics	Nopco Chemical Co., Plastics Div.
Novodur	Polyacrylonitrile-butadiene-styrene	Farbenfabriken Bayer, A. G.
Opalon	Vinyl chloride resins and compounds	Monsanto Co.
Paraplex	Polyester resins, acrylic-modified polyester resins	Rohm & Haas Company

TABLE C.9 (continued) Trade Names, Composition, and Manufacturers of Various Plastics

Trade name	*Composition*	*Manufacturer*
Permelite	Melamines	Melamine Plastics, Inc., Div. of Fiberlite Corp.
Petrothene	Polyethylene resins, polypropylene resins	U.S. Industrial Chemicals Co.
Piccoflex	Styrene-copolymer resins	Pennsylvania Industrial Chemical Corp.
Piccolastic	Styrene-polymer resins	Pennsylvania Industrial Chemical Corp.
Plaskon	Nylons, melamines, phenolics, polyesters	Allied Chemical Corp.
Pleogen	Alkyds, polyesters, copolymers	Mol-Rez Div., American Petrochemical Corp.
Plexiglas	Acrylics	Rohm & Haas Company
Pliovic	Polyvinyl chlorides	The Goodyear Tire & Rubber Co., Chemical Div.
Plyophen	Phenolic resins	Reichhold Chemicals, Inc.
Poly-Eth	Polyethylene resins	Gulf Oil Corp., U.S. Div. of Gulf Oil Corp.
Polylite	Polyester resins	Reichhold Chemicals, Inc.
Polypenco	Acrylics, chlorinated polyethers, fluorocarbons, nylons, polycarbonates	Polymer Corp.
Resimene	Urea and melamine resins	Monsanto Co.
Resinox	Phenolic resins and compounds	Monsanto Co.
Rhonite	Urea resins	Rohm & Haas Company
Roylar	Polyurethanes	Uniroyal Chemical, Div. of Uniroyal Inc.
Ryertex	Laminated phenolics and rigid polyvinyl chloride extrusions	Joseph T. Ryerson & Son, Inc., Industrial Plastics and Bearings Sales Div.
Super Dylan	Polyethylene	Sinclair-Koppers Co.
Supreme	Polyethylenes	Johns-Manville Company
Sylplast	Urea-formaldehyde compounds	FMC Corp., Organic Chemicals Div.
Teflon	Fluorocarbon resins	E. I. du Pont de Nemours & Co., Inc.
Tenite	Cellulose acetate, cellulose-acetate-polyethylene, polypropylenes, urethane elastomers, copolymers	Eastman Chemical Products, Inc., Sub. Eastman Kodak Co.
Tetran	Fluorocarbons	Pennsalt Chemicals Corp.
Texin	Urethane elastomers	Mobay Chemical Company
Thioment	Polyisoprenes	Atlas Minerals & Chemicals Div., The Electric Storage Battery Co.
Ultrapas	Melamine resins	Dynamit Nobel, A. G.
Ultrathene	Ethylene-vinyl acetates	U.S. Industrial Chemicals Co.
Ultron	Polyvinyl chlorides	Monsanto Co.
Vibrathane	Urethane elastomers	Uniroyal Chemical, Div. of Uniroyal Inc.
Vibrin	Polyester resins	Uniroyal Chemical, Div. of Uniroyal Inc.
Vitel	Polyesters	The Goodyear Tire & Rubber Co., Chemical Div.
Viton	Synthetic rubbers	E. I. du Pont de Nemours & Co., Inc.
Vitroplast	Polyester cements	Atlas Minerals & Chemicals Div., The Electric Storage Battery Co.
Vyron	Polyvinyl chlorides	Industrial Vinyls, Inc.

Notes:

Most nylon resins listed in this table are used for injection molding, and test values are determined from standard injection-molded specimens. In these cases a single typical value is listed. Exceptions are MoS_2-filled nylon and direct-polymerized (castable) nylon, which are sold principally in semifinished stock shapes. Ranges of values listed are based on tests on various forms and sizes produced under varying processing conditions.

Because single values apply only to standard molded specimens, and properties vary in finished parts of different sizes and forms produced by various processes, these values should be used for comparison and preliminary design considerations only. For final design purposes the manufacturer should be consulted for test experience with the form being considered. Listed values should not be used for specification purposes.

For Conversion factors see Table C.10.

TABLE C.11 Properties of Silicate Glasses*

Most of the commercially produced glass is for windows, bottles, and inexpensive containers; it is a soda-lime-silica glass of fairly uniform composition, similar to glass No. 0080 in the table below and in Table 1-93. The following tables on glasses (Tables 1-92 through 1-103) deal largely with that one-tenth of the glass output for which special properties are required. All data are subject to normal manufacturing variations.

Silica glass is inherently high in viscosity and melting point. These are reduced by fluxes such as Na_2O, K_2O, and B_2O_3. Soda and potash glasses have a high expansion coefficient (column 7), while that of fused silica is very low. Because the borosilicate glasses are intermediate, and their thermal shock resistance is high (e.g., Corning Code 7740 glass), they are widely used for laboratory and kitchen glassware. Aluminosilicate glasses are hard, heat-resisting, and of high chemical durability. Glass hardness (indentation) correlates closely with the elastic modulus (column 14). Lead oxide is also used as flux, with a result of reduced softening point and high refractive index: hence its uses for optical glass and art glass.

Sealing of glass with metal calls for close control of the coefficient of expansion (column 7 and Figure 1-99).

EXPLANATION OF COLUMNS:

Column 5:

B—blown ware
M—multiform
U—panels
P—pressed ware
R—rolled sheet
LC—large castings
S—plate glass
T—tubing and rod

Column 6:

[2] Since weathering is determined primarily by clouding, which changes transmission, a rating for the opal glasses is omitted.

[3] These borosilicate glasses may rate differently if subjected to excessive heat treatment.

Column 8:

Normal service: No breakage from excessive thermal shock is assumed.

Extreme limits: Glass will be very vulnerable to thermal shock. Recommendations in this range are based on mechanical stability considerations only. Tests should be made before adopting final designs. These data are approximate only.

Column 9:

Based on plunging sample into cold water after oven heating. Resistance of 100°C means no breakage if heated to 110°C and plunged into water at 10°C. Tempered samples have over twice the resistance of annealed glass. These data are approximate only.

Column 10:

[4] These data are estimated.

Resistance in °C is the temperature differential between the two surfaces of a tube or a constrained plate that will cause a tensile stress of 1000 psi on the cooler surface.

Column 11:

Viscosity is given in poises. At the strain point the stresses are significantly reduced in a matter of hours, while at the annealing point there is adequate stress reduction in minutes.

Column 12:

Data show relative resistance to sandblasting.

Column 15:

Data at 25°C are extrapolated from high temperature readings and are approximate only.

Plate or float	1	13.13	79	49
Gray[a]	$\frac{1}{4}$	3.28	43	46
Bronze[a]	$\frac{1}{4}$	3.28	49	45
Green[a]	$\frac{1}{4}$	3.28	75	46
Double[b]	$\frac{1}{4}$ each	6.56	78	—

Note: Many types of glass are available, including tempered heat-strengthened glass, laminated shatter-proof glass, conductive-coated glass, reflective-coated glass. Several double-pane combinations are offered.

Direct 90° transmittance of solar ultraviolet radiation through non-tinted window glass is about 85 percent as high as the values for total solar energy transmittance. Ultraviolet transmittance of gray or bronze glass is lower.

Infrared transmittance is considerably lower than visual transmittance. This is significant in view of the large percentage of infrared radiation from most sources.

Visible reflectance of untinted glass is about 8 percent.

Approximate shading coefficients, ASHRAE, $\frac{1}{4}$-in. glass only: clear, 0.93; gray, 0.67; bronze, 0.65; green, 0.67.

Overall heat transfer coefficient of window area (air to air) is usually assumed to be 1.0 Btu/ft² hr, but it is lower if there is no wind.

For other data on shading coefficients, spectral transmittance, coated glass, special glasses, etc., see Tables I-91, 2-19, and 7-19.

[a] Transmittance of tinted glass depends on depth of tint.

[b] Two $\frac{1}{4}$-in. panes with $\frac{1}{2}$-in. air space, sealed.

Note: For weight-density in kg/m^3, multiply value in lb/ft^3 by 16.02.

TABLE C.14 Properties of Natural Fibers*

Because there are great variations within a given fiber class, average properties may be misleading. The following typical values are only a rough comparative guide.

Name	*Specific gravity*	*Tenacity, g/denier*	*Tensile strength, 10^3 psi*	*Elongation at break (dry), %*	*Standard regain, % of dry*[b]	*Fiber diameter, microns*	*Fiber length, in.*	*Fiber shape and kind*	*Resistant to*
ANIMAL ORIGIN									
Wool	1.32	1.0–1.7	17–29	23–35	15–18	17–40	1.5–5	Oval, crimped, scales	Age, weak acids, solvents
Silk	1.25	3.5–5	90	20–25	10	10–13		Flexible, soft, smooth	Heat, solvents, weak acids, wear
Cashmere						15–16	1–4	Round, scales, soft	
Mohair	1.32	1.2–1.5		30	13	24–50	6–12	Round, silky	Wear, age, solvents, weak acids
Camel hair	1.32	1.8		40	13	10–40	1–6	Oval, striated	Age, solvents
VEGETABLE ORIGIN									
Cotton	1.54	2–5	30–120	5–11	7.5–8.5	10–20	0.5–2	Flat, convoluted, ribbon	Age, heat, washing, wear, solvents, alkalies, insects
Jute (bast)	1.5		50	1–1.5	14	15–20		Woody, rough, polygon	
Sisal (leaf)	1.49	2.2	75	2–2.5	13	10–30	Strand 30–40	Stiff, straight	
Flax (bast)	1.52	4–7		2–3	12	15–18	Strand 40–50	Soft, fine	Age, solvents, washing, insects, weak acids, and alkalies
Kenaf (bast)			45			15–30		Polygon or oval	
Hemp (bast)	1.48			2		18–25	Strand 30–70	Polygon or oval, irregular	
Henequen (leaf)			60				Strand 30–60	Finer than sisal	
Abaca (leaf) (Manila)	1.48	2.3–2.9	100	2–3	13		Strand 30–120		
MINERAL ORIGIN									
Asbestos	2.5		40–200			Various	0.5–10	Smooth, straight	Heat to 400 deg C, acids, chemicals, organisms
Glass[a]	2.5	7–12	200–500	3–4.5	0	Various		Circular, smooth	Chemicals, insects
Silicate[a] (Ca, Al, Mg)	2.85				0				Heat to 900 deg C, most chemicals, insects, rot

Note: Wide variations may be expected, especially for different grades of cotton. Wet strength is lower (for rayon, very much lower), but it depends on the duration of soaking. The strength of yarn is only a fraction of the cumulative strength of all individual fibers.

Most fibers exhibit relaxation of stress at constant strain and also increase in elongation at constant load (creep). The stress-strain curve is greatly affected by the rate of extension. When the stress is removed, there is a quick elastic recovery, a delayed recovery, and a permanent set. Hence the elastic behavior of any fiber depends on its stress-strain history. The elastic recoveries of nylon and wool are high; those of cotton, flax, and rayon are much lower.

The heat capacity (specific heat) of most fibers is about one-third that of water.

Other fibers: Fur hair is slightly coarser than silk fibers. Camel and llama hairs are almost as coarse as wool but only about one-third the size of human hair. Horse hair is over 100 microns; hog bristles, over 200 microns. Jute, sisal, and hemp are intermediate between cotton and wool. These are rough average sizes, and many natural fibers range 50% above or below such averages.

[a] Here classified as natural fibers for convenience, although they are man-made by processing.

[b] Expected equilibrium moisture regain of dry fiber, in percent of dry weight, when exposed in air at 70 deg F, 65% relative humidity.

*Compiled from several sources.

TABLE C.16 Properties of Rubbers and Elastomers*

Elastomers cannot be classified in any brief and simple manner, nor are they well characterized by the usual mechanical tests. The terms *rubber* and *synthetic rubber* are loosely applied to a great variety of elastic materials, from pure gum natural rubber and pure synthetics to cured, compounded, filled, and even reinforced products.

ASTM designations (D1418) by chemical polymer description are used in the following table; yet within each class the properties can vary widely, depending on the exact composition, heat treatment service temperature, and application. Typical uses, such as rubber springs and cushioning, permit an almost unlimited number of combinations of design variables.

Mechanically, rubbers may be expected to lose strength rapidly with increase in temperature, to show a large hysteresis in stress-strain behavior, to exhibit marked creep and set, and to be greatly affected by rates of load application or frequency of repeated stress. "Heat build-up", i.e., increase in temperature in service, as well as deterioration from environment (sunlight, oils, ozone, etc.) will reduce the valuable properties of many rubbers, both natural and synthetic.

The following data apply to typical samples of commercial elastomers for common uses.

KEY:

A—Acetone
B—Benzene
C—Carbon tetrachloride
D—Carbon disulfide
E—Phenol
F—Sulfur compounds
G—Glycerol or glycol
H—Hexane
I—Acids
J—Alkalies
K—Ketones
L—Alcohols
M—Ammonia
N—Turpentine
O—Coal derivatives; bitumens
P—Petroleum products
R—Aromatics
S—Salts
T—Heat or high temperature
U—Ultraviolet
V—Vegetable oils
W—Weathering
X—Oxidation
Y—Aging
Z—Ozone

Appendix E. Miscellaneous

TABLE E.1 Sizes and Allowable Unit Stresses for Softwood Lumber

American Softwood Lumber Standard. A voluntary standard for softwood lumber has been developing since 1922. Five editions of Simplified Practice Recommendation R16 were issued from 1924–53 by the Department of Commerce; the present NBS voluntary Product Standard PS 20-70, "American Softwood Lumber Standard", was issued in 1970. It was supported by the American Lumber Standards Committee, which functions through a widely representative National Grading Rule Committee.

				12	$11\frac{1}{4}$	$11\frac{1}{2}$
				14		$13\frac{1}{2}$
				16		$15\frac{1}{2}$
Timbers	5 and thicker		$\frac{1}{2}$ off	5 and wider		$\frac{1}{2}$ off

[a] Maximum moisture content of 19% or less.

[b] Boards less than the minimum thickness for 1 in. nominal but $\frac{5}{8}$ in. or greater thickness dry ($\frac{11}{16}$ in. green) may be regarded as American Standard Lumber, but such boards shall be marked to show the size and condition of seasoning at the time of dressing. They shall also be distinguished from 1-in. boards on invoices and certificates.

* Reprinted from: "American Softwood Lumber Standard", NBS PS 20-70, National Bureau of Standards, 1970; available from Superintendent of Documents.

Note: This table applies to boards, dimensional lumber, and timbers. The thicknesses apply to all widths and all widths to all thicknesses.

TABLE E.1 (continued) Sizes and Allowable Unit Stresses for Softwood Lumber

The "American Softwood Lumber Standard", PS 20-70, gives the size and grade provisions for American Standard lumber and describes the organization and procedures for compliance enforcement and review. It lists commercial name classifications and complete definitions of terms and abbreviations.

Eleven softwood species are listed in PS 20-70, viz., cedar, cypress, fir, hemlock, juniper, larch, pine, redwood, spruce, tamarack, and yew. Five dimensional tables show the standard dressed (surface planed) sizes for almost all types of lumber, including matched tongue-and-grooved and shiplapped flooring, decking, siding, etc. Dry or seasoned lumber must have 19% or less moisture content, with an allowance for shrinkage of 0.7–1.0% for each four points of moisture content below the maximum. Green lumber has more than 19% moisture. Table A illustrates the relation between nominal size and dressed or green sizes.

National Design Specification. Part b is condensed from the 1971 edition of "National Design Specification for Stress-Grade Lumber and Its Fastenings," as recommended and published by the National Forest Products Association, Washington, D.C. This specification was first issued by the National Lumber Manufacturers Association in 1944; subsequent editions have been issued as recommended by the Technical Advisory Committee. The 1971 edition is a 65-page bulletin with a 20-page supplement giving "Allowable Unit Stresses, Structural Lumber," from which Part b has been condensed. The data on working stresses in this Supplement have been determined in accordance with the corresponding ASTM Standards, D245-70 and D2555-70.

Part b. Species, Sizes, Allowable Stresses, and Modulus of Elasticity of Lumber

Normal loading conditions: Moisture content not over 19%, No. 1 grade, visual grading. To convert psi to N/m^2, multiply by 6 895.

Species[a]	*Sizes, nominal*	*Typical grading agency, 1971*[b]	*Allowable unit stresses, psi*[d]				*Modulus of elasticity, psi*
			Extreme fiber in bending[c]	*Tension parallel to grain*	*Compression perpendicular*	*Compression parallel*

	2 or 4 × 6+	WC	1 300	775	280	925	1 500 000

Note: Allowable unit stresses in horizontal shear are in the range of 60–100 psi for No. 1 grade.

[a] Grade designations are not entirely uniform. Values in the table apply approximately to "No. 1." There is seldom more than one better grade than No. 1, and this may be designated as select, select structural, dense, or heavy. In addition to lower grades 2 and 3, there may be other lower grades, designated as construction, standard, stud, and utility. In bending and tension the allowable unit stresses in the lowest recognized grade (utility) are of the order of $\frac{1}{8}$ to $\frac{1}{6}$ of the allowable stresses for grade No. 1. The tabular values for allowable bending stress are for the extreme fiber in "repetitive member uses," and edgewise use. The original tables give correction factors, which are less than unity for moist locations and for short-time loading; they are greater than unity if the moisture content of the wood in service is 15% or less. In general, all data apply to uses within covered structures. From the extensive tables, only the No. 1 grade in nominal 2 × 4 size and 2-in. or 4-in. planks, 6 in., and wider have been selected for illustration.

In a few cases the allowable stresses specified for the Canadian products will vary slightly from those given here for the same species by the U.S. agencies.

[b] Grading agencies represented by letters in this column are as follows:

NC = National Lumber Grades Authority (a Canadian agency)
NH = Northern Hardwood and Pine Manufacturers Association
NL = Northern Lumber Manufacturers Association
RI = Redwood Inspection Service
SP = Southern Pine Inspection Bureau
WC = West Coast Lumber Inspection Bureau
WW = Western Wood Products Association

[c] It is assumed that all members are so framed, anchored, tied, and braced that they have the necessary rigidity.

[d] For short term loads, these values may be increased: add 15% for 2-month snow load; add 33% for wind or earthquake; add 100% for impact load.

TABLE E.4 Commercial Copper Tubing*

The following table gives dimensional data and weights of copper tubing used for automotive, plumbing, refrigeration, and heat exchanger services. For additional data see the standards handbooks of the Copper Development Association, Inc., the ASTM standards, and the "SAE Handbook."

Dimensions in this table are actual specified measurements, subject to accepted tolerances. Trade size designations are usually by actual OD, except for water and drainage tube (plumbing), which measures 1/8-in. larger OD. A 1/2-in. plumbing tube, for example, measures 5/8-in. OD, and 2-in. plumbing tube measures 2 1/8-in. OD.

KEY TO GAGE SIZES

Standard-gage wall thicknesses are listed by numerical designation (14 to 21), BWG or Stubs gage. These gage sizes are standard for tubular heat exchangers. The letter *A* designates SAE tubing sizes for automotive service. Letter designations *K* and *L* are the common sizes for plumbing services, soft or hard temper.

OTHER MATERIALS

These same dimensional sizes are also common for much of the commercial tubing available in aluminum, mild steel, brass, bronze, and other alloys. Tube weights in this table are based on copper at 0.323 lb/in^3. For other materials the weights should be multiplied by the following approximate factors:

aluminum	0.30	monel	0.96
mild steel	0.87	stainless steel	0.89
brass	0.95		

Size, OD		*Wall Thickness*			*Flow Area*		*Metal*	*Surface Area*

Note: The present trend, especially for sheet and strip, is to quote thickness as decimal or fraction of an inch rather than gage number. ANSI Standard preferred thicknesses have been adopted. These preferred sizes for thickness of uncoated sheet, strip, and plate under 0.25 in. are as follows: .224, .220, .180, .160, .140, .125, .112, .100, .090, .080, .071, .063, .056, .050, .045, .040, .036, .032, .028, .025, .022, .020, .018, .016, .014, .012, .011, .010, .009, .008, .007, .006, .005, .004.

KEY: (1) Manufacturer's standard for hot- and cold-rolled uncoated carbon steel sheet and most alloy steel sheet.
(2) U.S. Standard for cold-rolled steel strip and stainless and nickel alloy sheet.
(3) Birmingham or Stub for hot-rolled carbon and alloy steel strip and tubing.
(4) Washburn and Moen, Roebling, or U.S. Steel for steel wire.
(5) American wire gage or Brown and Sharpe for non-ferrous wire, sheet, and strip.

Dimensions in approximate decimals of an inch.

TABLE E.6 Properties of Typical Gaseous and Liquid Commercial Fuels*

Gaseous fuels	*Composition, percent by volume*								*Mol wt of fuel*	*Theor. air/fuel ratio by wt*	*Higher heating value, Btu/lb$_m$*	*Density, lb$_m$/ft^3*
	H_2	*N_2*	*O_2*	*CH_4*	*CO*	*CO_2*	*C_2H_4*	*C_6H_6*				
Blast furnace gas	1.0	60.0	—	—	27.5	11.5	—	—	29.6	0.667	1,170	.075 5[a]
Blue water gas	47.3	8.3	0.7	1.3	37.0	5.4	—	—	16.4	3.759	6,550	.042 2[a]
Carb. water gas	40.5	2.9	0.5	10.2	34.0	3.0	6.1	2.8	18.3	7.299	11,350	.046 6[a]
Coal gas	54.5	4.4	0.2	24.2	10.9	3.0	1.5	1.3	12.1	10.87	16,500	.031 1[a]
Coke-oven gas	46.5	8.1	0.8	32.1	6.3	2.2	3.5	0.5	13.7	17.24	17,000	.032 6[a]
Natural gas (15.8% C_2H_6)	—	0.8	—	83.4	—	—	—	—	18.3	17.24	24,100	.045 1[a]
Producer gas	14.0	50.9	0.6	3.0	27.0	4.5	—	—	24.7	14.29	2,470	.063 6[a]

Liquid commercial fuels	*Vapor*		*Gravity, API, 60°F*	*Distillation*			*Flash point, °F*	*Viscosity, centi-stokes, 100°F*	*Mol wt of fuel*	*Theor. air/fuel ratio by wt*	*Higher heating value, Btu/lb$_m$*	*Density, lb$_m$/ft^3*
	c_p, 60°F	*c_p/c_v, 60°F*		*10%, °F*	*90%, °F*	*End point, °F*						
	(approximately)											
Gasoline	0.4	1.05	63	121	320	397	0	—	113	14.93	20,460	43.8[b]
Gasoline	0.4	1.05	63	118	330	410	0	—	126[c]	14.97	20,260	46.1[b]
Kerosene	0.4	1.05	41.9	370	510	546	130	—	154[c]	14.99	19,750	51.5[b]
Diesel oil (1-D)	0.4	1.05	42	—	550	—	100	1.4–2.5	170	15.02	19,240	54.6[b]
Diesel oil (2-D)	0.4	1.05	36	—	540–576	—	125	2.0–5.8	184	15.06	19,110	57.4[b]
Diesel oil (4-D)	0.4	1.05	—	—	—	—	130	5.8–26.4	198	14.93	18,830	59.9[b]

[a] Based on dry air at 25°C and 760 mm Hg.

[b] Based on H_2O at 60°F, 1 atm ($\rho = 62.367$ lb$_m$/ft^3).

[c] Estimated.

*Abridged from: "Engineering Experimentation", G.L. Tuve and L.C. Domholdt, McGraw-Hill Book Company, 1966; and "The Internal Combustion Engine", 2nd ed., C.F. Taylor and E.S. Taylor, International Textbook Co., 1961.

Note: For heating value in J/kg, multiply the value in Btu/lb$_m$ by 2324. For density in kg/m^3, multiply the value in lb/ft^3 by 16.02.

TABLE E.7 COMBUSTION DATA FOR HYDROCARBONS*

Hydrocarbon	*Formula*	*Higher heating value (vapor),* Btu/lb_m	*Theor. air/fuel ratio, by mass*	*Max flame speed, ft/sec*	*Adiabatic flame temp (in air), °F*	*Ignition temp (in air), °F*	*Flash point, °F*	*Flammability limits (in air), % by volume*
